L. indica has yielded β-amyrenyl acetate, germanicyl acetate, taraxasteryl acetate, α-lactucerol, β-amyrin, β-sitosterol, stigmasterol and an unidentified aliphatic alcohol (Hui & Lee 1971).

L. sativa fresh aerial parts have yielded [w/w] 0.0002% lactucopicrin, 0.0001% *lactucin*, 0.00015% 11β,13-dihydro-*lactucin*, 0.0025% 3β-OH-11β,13-dihydro-acanthospermolide, 0.0005% 3β-14-dihydroxy-11β,13-dihydrocostunolide, 0.0017% β-sitosterol, 0.0005% β-sitosterol glucoside, 0.02% lupeol, 0.013% lupeyl acetate (Mahmoud et al. 1986), vitamin A, vitamin B1, vitamin C, vitamin E, vitamin K and traces of an essential oil (Watt & Breyer-Brandwijk 1962). Up to 0.02% of a mydriatic alkaloid was isolated from the flowering plant, identified as *hyoscyamine* (Felter & Lloyd 1898). Traces of *morphine* [2-10ng/g] have also been found in lettuce (Hazum et al. 1981). The latex has also yielded 10.26% rubber (Watt & Breyer-Brandwijk 1962). Latex from L. sativa cv. 'Diana' and cv. 'Benita' was shown to contain mostly lactucopicrin-15-oxalate, as well as lactucopicrin, *lactucin*, *lactucin*-15-oxalate, 8-deoxylactucin-15-oxalate, 15-deoxylactucin-8-sulfate, 11,13-dihydro-8-deoxylactucin-15-glycoside [jacquinellin glycoside], 15-p-OH-phenylacetyl-*lactucin*-8-sulfate and 2,3,4-tri-O-(4-OH-phenylacetyl)glucopyranose. The cultivars 'Capitan', 'Cobham Green', and 'Salinas' have similar chemical profiles to 'Diana' (Sessa et al. 2000). Seeds of L. sativa cv. 'Grand Rapids' yielded [as % of sterol fraction] 52% β-sitosterol, 14% campesterol, 12% stigmasterol, 12% stigmast-7-en-3β-ol, 6% Δ7-avenasterol and 4% Δ5-avenasterol (Knights & Middleditch 1972).

L. serriola latex has been found to contain *lactucin*, *lactucin*-15-oxalate, 8-deoxylactucin-8-sulfate, 15-p-OH-phenylacetyl-*lactucin*-8-sulfate, lactucopicrin, lactucopicrin oxalate, and 2,3,4-tri-O-(4-OH-phenylacetyl)-glucopyranose and homologues (Sessa et al. 2000). L. serriola leaf [harv. Jan.] from Brisbane, Queensland [Australia], tested positive for alkaloids; roots only gave a weak positive in one test. Herbage from Yarraman, Qld. [harv. Oct.] also gave positive tests, except for one sample, which was a very young plant (Webb 1949).

L. virosa latex has yielded α-lactucerin [lactucone, taraxasterol acetate], β-lactucerin, c.50% α-lactucerol [taraxasterol, pyrethrol, saussurol], *lactucin* [c.0.2% of plant], *lactucin*-15-oxalate, 15-deoxylactucin-8-sulfate, 8-deoxylactucin-15-oxalate, lactucopicrin, lactucopicrin oxalate, jacquinellin glycoside, germanicol, β-amyrin, mannitol and inositol (Bauer & Brunner 1939; Bauer & Schub 1929; Budavari et al. ed. 1989; Forst 1941; Schenck & Graf 1937; Sessa et al. 2000; Simpson 1944). Up to 0.02% of a mydriatic alkaloid was isolated from the plant, identified as *hyoscyamine*; however, no *hyoscyamine* was found in samples of German or English lactucarium (Felter & Lloyd 1898). The fresh latex has yielded neo-*lactucin*, which was proposed to be a possible precursor, converting to *lactucin* during the drying of the latex (Bauer & Brunner 1937).

Lactuca virosa is an annual or biennial herb; roots foetid; stems usually solitary, erect, to 2m, branched, glabrous or setose below. Leaves obovate-oblong, dentate to pinnatifid with wide lobes, spinulose on midrib beneath, lateral veins on underside smooth. Inflorescence a long, pyramidal panicle; capitula with c.15 florets; involucre cylindrical; bracts in several rows, with appressed auricles; corolla ligulate, ligules pale yellow; stamens 5, epipetalous. Ovary inferior, unilocular; ovule solitary, basal, anatropous; style solitary, with 2 stigmatic branches. Achenes 6-10mm long, body elliptical, compressed, narrowly winged, rugose, 5-ribbed on one side, blackish, beaked, beak as long as body, lighter in colour; pappus of 2 equal rows of simple hairs.

In dry, sandy or stony places; s., w. & c. Europe, also cultivated, and naturalised as a weed in many areas over the world (Tutin et al. ed. 1964-1980).

L. virosa and L. serriola have frequently been confused, due to the fact that they both exist in various forms which can overlap in appearance. When bruised or broken, L. virosa can be distinguished by its 'opium poppy-like' smell [**Papaver** somniferum]; L. serriola has a smell closer to that of L. sativa. Fresh achenes of L. virosa are a strong purplish or maroon in colour; fresh achenes of L. serriola are smaller, and olive-grey in colour (Oswald 2000).

LAGGERA

(Compositae/Asteraceae)

Laggera alata *(D. Don.) Sch.-Bip. ex Oliv.* **(L. angustifolia** *Hayata*; **L. heudelotii** *C.D. Adams*; **Blumea alata** *(D. Don.) DC.*; **B. heudelotii** *(C.D. Adams) Lisowski*; **Conyza alata** *Roxb.*; **Erigeron alatum** *D. Don.*; **Inula exsiccata** *H. Lév.*; **Vernonia alata** *F. Heyne ex DC.***)** – anriandro

The leaf of this shrubby African herb is smoked as a 'narcotic' by the Bapunu and Bavungu of Gabon (Watt 1967). The herb is strongly aromatic, with a sweet thymol-like odour. It is also eaten as a vegetable in parts of Nigeria, and in other parts of Africa it is used as a disinfectant, and to treat rheumatic pain, fevers, and pneumonia. In TCM, it is an ingredient in an ointment used to apply to skin tumours (Onayade et al. 1990). In Tanganyika, the related L. brevipes is used to treat 'sexual disorders'; in other areas of s.e. Africa, a decoction of the plant is given to a woman after childbirth (Watt & Breyer-Brandwijk 1962).

L. alata growing wild in Nigeria [harv. August] yielded an essential oil containing 44% 2,5-dimethoxy-p-cymene, 16% sabinene, 12% sesquiterpenes, 3% 6-OH-carvotanacetone and 2% 4-OH-carvotanacetone-7-O-angelate (Onayade et al. 1990); 5-desoxylongilobol has also been found in the plant (Buckingham et al. ed. 1994). Another study, using material from Madagascar, obtained 0.476% essential oil from aerial parts, containing eudismane sesquiterpenes [7-epi-pseudoeudesmol, 7-epi-β-eudesmol, 7-epi-α-eudesmol and isointermedeol], juniper *camphor*, β-dihydroagarofuran and β-selinene (Raharivelomanana et al. 1998).

Laggera alata is a strongly aromatic erect woody herb up to 3m or more tall. Leaves alternate, round-sided, broad-obtuse, venation clearly visible; stem leaves broadly oblong-elliptic and obtuse; leaves in the inflorescence elliptic-lanceolate; stem and undersurface of leaves puberulous; stem-wings c.3mm broad. Capitula 1cm or more diam., numerous, usually more than 20 in a spreading paniculate inflorescence; florets usually mauve in numerous heads c.1.3cm long; involucral bracts puberulous; calyx epigynous, reduced to a pappus of persistent or caducous hairs/bristles; corolla sympetalous, 4-5-fid, disc-florets actinomorphic, filiform, ligulate or rarely bilabiate, ray florets zygomorphic; stamens 5, rarely 4, epipetalous; filaments free; anther base not tailed. Ovary inferior, 1-locular, 1-ovuled; ovule erect from the base; style arms clavate without an apical appendage. Pappus bristles numerous; achene sessile, sometimes beaked.

Guinea, Sierra Leone, Liberia, Ghana, Nigeria, British Cameroons, Madagascar [highlands, e. coast], w. coast of Africa (Hutchinson & Dalziel 1954-1972).

LAGOCHILUS

(Labiatae/Lamiaceae)

Lagochilus ferganensis *Ikramov*
Lagochilus gypsaceus *Vved.*
Lagochilus inebrians *Bunge* – inebriating mint, intoxicating lagochilus
Lagochilus proskorjakovii *Ikramov*
Lagochilus setulosus *Vved.* **(L. hirtus** *Lapin***)**
Lagochilus spp. – lagochilus

In the Steppes of Turkestan, central Asia, the shrub L. inebrians is well known to the Uzbek, Turkmen, Tartar and Tajik, who have used it for centuries. The fruiting tops, leaves and stems are collected in October, and flowers are discarded. The herb is bundled and hung to dry in the house during winter; its strength is said to increase on drying, as does its aroma. For use, it is boiled or infused with water, sugar and honey to make a strong tea that acts as a sedative, hypotensive and antispasmodic, with no undesirable side-effects. This 'standard tea' [a.k.a. '5-10% extract'] is prepared by taking a pre-warmed teapot, filling to 1/3 with leaves and flowers, pouring in boiling water to the top, then covering and leaving wrapped in a tea cosy to infuse for 8-10hrs; this may keep for 2-3 days in a fridge. Modernly, it has been used in Russia as a haemostatic, and to treat nervous disorders, skin disorders, glaucoma and allergies. However, due to the current scarcity of the plant, and lack of organised cultivation efforts, any use today would be of synthetic derivatives or of related species. For example, L. ferganensis, L. gypsaceus, L. proskorjakovii and L. setulosus have the same properties as L. inebrians (Emboden 1979a; Schultes 1966; Turney 2004; Tyler 1966).

The psychotropic effects of L. inebrians are thought to stem largely from its content of lagochiline (Abramov et al. 1960; Pulatova 1960), an epoxylabdane or grindelane diterpene alcohol, sometimes referred to as an alkaloid in the older literature [such as Akopov 1954a] (Chizhov et al. 1969; Tyler 1966). Lagochiline has sedative effects, but is not very soluble in water or organic solvents. Two derivatives of lagochiline, lagochiline tetraacetate and lagochilidine [inebrine, a synthetic derivative], have similar sedative properties, but are more readily soluble, and were thus considered better candidates for potential medicinal use than lagochiline (Abramov 1959). Lagochiline acetate has shown sedative activity in humans at a dose of 30mg, and was hypotensive in dogs; like lagochiline, it is also haemostatic [see below] (Asliddinov 1958).

L. gypsaceus has a similar chemical composition to L. inebrians [see below] (Radchenko 1964), and has the same pharmacological properties (Turney 2004).

L. hirsutissimus has yielded 1.2% lagochiline (Sharipova et al. 1974), and the diterpene lactone lagochirzidin (Nurmatova et al. 1980).

L. inebrians has yielded lagochiline [lagochilin; 15.67% in resin, in one analysis], lagochiline tetraacetate, lagochiline 3-monoacetate, 3 diacetates of lagochiline, vulgarol [a labdane diterpenoid], and the alkaloid stachydrine [0.2%] (Abramov 1957; Abramov & Yaparova 1964; Islamov et al. 1978, 1981a, 1981b; Pulatova & Khazanovich 1964). At the beginning of the growing season, 1% lagochiline and 3% lagochiline tetraacetate were found; during full growth, this was reversed to yield 3% lagochiline and 1% lagochiline tetraacetate (Abramov & Yaparova 1964). Compared to wild plants, cultivated plants yielded 20% more lagochiline, as well as higher levels of tannins, and lower levels of carotene (Abramov et al. 1960).

L. pubescens has yielded lagochiline, and 8 acetyl-derivatives of lagochiline (Mavlankulova et al. 1978).

L. seravschanicus did not contain any detectable lagochiline (Radchenko 1964).

L. setulosus has yielded 0.608% stachydrine (Pulatova & Khazanovich 1964), lagochiline, tannins, resins, essential oil, ascorbic acid, carotene, and sugars. It has been suggested as a medicinal substitute for L. inebrians, due to their very similar chemical compositions (Pulatova 1960; Turney 2004).

A range of Lagochilus spp. were studied and all found to contain coumarins [0.3-2.5%], lipids [4.25-8.3%] and tannins [2.0-3.3%] (Sharipova et al. 1974). Members of the genus have also yielded new grindelane-derived diterpenoids (Zainutdinov et al. 1976). Extracts of Lagochilus spp. [given s.c.] were antispasmodic in frogs and rats, antagonising spasms induced by *camphor*, *caffeine*, picrotoxin, and *strychnine* (Akopov 1954b). Extracts or infusions of Lagochilus spp., as well as lagochiline, showed haemostatic activity (Akopov 1954a). An infusion of L. inebrians [old and possibly stale dried herb] was compared to chamomile [see **Anthemis and Matricaria**] in effect; also, the aroma of the dried flowers [which more or less lack aroma when fresh and growing, unlike the leaves] was compared to an intermediate between chamomile and hops [see **Humulus**] (Turney 2004, pers. comm.).

Lagochilus inebrians is a perennial herb, 25-40cm tall; stems numerous, woody at base, simple or branched, densely leafy and densely long-haired, the hairs horizontally spreading, 1-3-jointed, interspersed with numerous capitate sessile glandular hairs. Leaves broad-ovate in outline, 3-5-parted, the lobes broad-ovate, rounded or toothed, cuneate at base, both sides covered with scattered 1-2-jointed spreading hairs and glands; petioles densely beset with 2-3-jointed spreading hairs, the lower 1.5-2cm, the upper dilated, 2-5mm long. Inflorescence semiverticils 4-6-flowered; bracts firm, reclinate, trigonous, subulate, covered with long 2-3-jointed spreading and sessile capitate glandular hairs; calyx tubular-campanulate-infundibular, calyx teeth recurved, broad-ovate or broadly triangular, 5-6mm long, spiny-pointed, the spine 1-1.5mm long, calyx tube covered with short 1-2-jointed thick hairs interspersed with sparse 3-5-jointed slender and numerous sessile capitate-glandular hairs; corolla pale pink, as long to 1.5 times as long as calyx, bilabiate, the tube with a ring of hairs near base; upper lip oblong, erect, flat, densely hairy outside, notched at apex, with 2 lobes; lower lip oblong, 3-lobed, with short straight lateral lobes, middle lobe larger, deeply bifid; stamens 4, as long as or shorter than corolla, the filaments glabrous or pubescent at base; anthers approximate, hirsute; style lobes equal. Seeds sharply trigonous, truncate at apex. Fl. Jun.-Aug.

Submontane plains and low foothills, on pebble-beds and fluviatile outwash, gravelly slopes, in wormwood-grass and wormwood forb associations [see **Artemisia**]; endemic to central Asia, described from Samarkand area (Shishkin ed. 1987) and Nuratau, the only places it has been found. Endangered; wild-harvest and export are prohibited. Difficult to cultivate, and seeds remain viable for only c.1yr; does not root from cuttings. Plant seeds where they are to grow, not too close together, 1-1.5cm deep if sown in autumn or 1.5-2cm deep if sown in spring; seed may require scarification. Sprouts c.6 months later, with 25-40% germination rate. Soil in native range is poor, dry, fine-grained and slightly clayey, and should be ploughed before cultivation; temperatures range from -15°C at night in winter, to over 45°C in summer days; direct sun all day. Roots like to grow deeply [although aerial parts grow slowly and remain short], so cultivation in pots might not be ideal (Turney 2004); however, this extra root growth may reflect the arid climate in which the plant grows, hence if grown in pots with some minimal watering, preferably from a tray underneath [plants don't like it too damp], the roots might not need the extra depth (pers. obs.).

LANCEA

(Scrophulariaceae)

Lancea tibetica *Hook. f. et Thomson* – depgul, Tibetan Lancea

This common Tibetan herb is used to manufacture an intoxicant in Ladakh, India, known as 'berzeatsink'. To prepare it, the roots are dried and roasted over a fire, before being powdered and mixed with tobacco [see **Nicotiana**]. The mixture is then either smoked, or drunk with milk. The effects are said to consist of a strong stimulation, which 'activates' the person consuming it (Navchoo & Buth 1990).

Nothings appears to be known of the chemistry of this species.

Lancea tibetica is a small, glabrous herb; stem very short, to 2.5-10.2cm; rootstock slender, horizontal, creeping. Leaves rosulate, or opposite on stem, 2.5-8.9cm long, obtuse or subacute, narrowed into a ½-amplexicaul petiole 0.6-2.54cm long, rather coriaceous, sometimes very obscurely toothed. Flowers in a very short terminal few-flowered raceme, sunk amongst the leaves; pedicels very short, bracteate, bracts lanceolate; calyx campanulate, 5-fid, lobes acute; corolla 1.9-2.5cm long, blue, tube dilated above; upper lip suberect, concave, 2-lobed; lower large, spreading, 3-lobed, hairy within, palate 2-convex; stamens didynamous, subexserted; anther cells diverging; style filiform; stigma 2-lamellate. Fruit globose, indehiscent, exserted, pea-sized, hardly fleshy. Seeds brown, numerous, small, subglobose, testa thin. Extremely variable in size and luxuriance. Fl. Aug.

In sandy and moist places, often closely appressed to the ground; alpine Himalaya and w. Tibet, India from Kashmir to Sikkim, 7620-12190m (Hooker 1857, 1954-1961).

LATUA

(Solanaceae)

Latua pubiflora *(Grisebach) Baillon* **(L. pubiflora** *(Gris.) Phil.***; L. venenosa** *R.A. Philippi***; Lycioplesium pubiflorum** *Gris.***)** – latué, latúe, latuy, latue-hue, árbol de los brujos ['sorcerer's tree'], palo mato ['tree that kills'], palo de bruja

This feared shrub is used by Mapuche-Huilliche shamans ['machi'] of s. Chile as their most important shamanic plant [see also **Datura**, **Desfontainia**, **Lobelia** and Ovidia pillopillo in *Endnotes*]. It is believed by shamans to give strength, good luck, curing properties and shamanic knowledge if respected, and harvested with appropriate prayers and offerings. It is also used by witches or 'black shamans' ['kalku'] to kill or otherwise harm people. Its use is usually kept very secret, and details are generally not shared with outsiders. Most 'ordinary' locals will attest that only witches use latué. The bark of stems or young shoots ['with plenty of sap'] is taken as an infusion or decoction, drunk during the night in small amounts at 20-30min. intervals. Actual doses of the herb have unfortunately not been disclosed by native informants. The leaves, or juice pressings from the leaves mixed with water or wine, are also sometimes used. Some say the fresh fruits are also equally intoxicating, but they have not tested positive for the tropane alkaloids found in the rest of the plant [the seeds however, have – see below]. The effects of the intoxication are similar to those of **Atropa**, **Brugmansia** or **Datura**, and the plant is sometimes given maliciously to poison others. Shamans are knowledgeable about appropriate doses for use of this plant, either to cure or to drive one insane, but they are reluctant to divulge such information. During the experience [which may last up to 36hrs or more], the shaman is said to perform 4-6 hours of dancing in a circle rigidly, with rhythmic stomping, and chanting of variations on the word 'latué'. Tobacco [see **Nicotiana**] is smoked throughout [perhaps instead **Lobelia** tupa?]. In curing rituals, there may be intermittent praying and attempts to drive out evil spirits from the patient [which sometimes involves slapping the patient with branches of **Cestrum** parqui]. The plant is sometimes thrown on a fire with other herbs [such as **Drimys** winteri (see **Canella**, **Drimys**) bark, Fabiana imbricata foliage (see *Endnotes*), **Cestrum** parqui leaves, **Ilex** paraguariensis foliage] to repel evil spirits and negative emotions (Mohl ed. 1858; Plowman et al. 1971; Rätsch 2001; Schleiffer ed. 1973; Schultes 1979; Schultes & Hofmann 1980).

L. pubiflora is also used in Mapuche initiations of pubescent boys and girls, after a days fast. A beverage is prepared by village elders from the juice of the fresh leaves and branches, collected in the early morning. This is drunk in two stages before the initiate is tied to a tree until the effects wear off, after which the initiate is believed to have "died and is born again to a new life" (Rätsch 2001).

In the past, Chileans used juice from L. pubiflora and **Drimys** winteri to poison fish. Medicinally, it may be applied externally as a bath or alcoholic tincture [sometimes with other herbs] to treat rheumatism. Fruits may be applied directly for this purpose, and infusions made from the leaves and fruit have been used as a sedative. Taken in small doses, the plant is believed to give strength (Rätsch 2001). L. pubiflora has reputedly been used as an aphrodisiac and an ingredient in love potions (Plowman et al. 1971). One psychonaut found the smoked leaves provided him with "a very pleasant physical effect with aphrodisiacal sensations" and compared the accompanying "spiritual relaxation and associative thinking" to the effects of **Brugmansia**. It was warned that not more than 1g be smoked at a time (Rätsch 2001). I have also found the leaves, when smoked in small amounts, to give effective short-term relief of mild asthma. These experiments were prompted by the known use of **Datura** leaves for the same purpose (pers. obs.).

Accidental poisonings sometimes occur, as the plant resembles another, known as 'tayu' [see below], which is decocted to treat shock and pain. Such poisonings are remedied by administration of **Solanum** nigrum ['hierba mora'], an Oxalis sp. ['culle'] and/or Raphithamnus spinosus ['espino negro'] fruit. In the case of S. nigrum, the plant is decocted and drunk during an 8 day fast, during which time the decoction is also applied externally [head, neck and back] as a compress. L. pubiflora is reputed to be able to cause death, though such deaths rarely occur (Plowman et al. 1971), probably due to the respect accorded to the plant and the centuries of accumulated knowledge regarding safe use (pers. obs.), or to the local fear of the properties of the plant (Rätsch 2001).

L. pubiflora leaves have yielded 0.07-0.185% alkaloids [70-86% *atropine*, 14-30% *hyoscine*]; stems yielded 0.24-0.496% alkaloids [87-92% *atropine*, 8-13% *hyoscine*]; seeds yielded 0.09% alkaloids [86% *atropine*, 14% *hyoscine*] (Plowman et al. 1971).

Latua pubiflora is a shrub or small tree 2-10m tall, with 1-several main trunks 3-25cm diam., spreading up and outwards from base; bark thin, streaked with corky, longitudinal fissures, becoming rough, reddish to greyish-brown; branches smooth, grey, with spines; branchlets cylindrical, current growth yellow-brown pubescent, glabrescent; spines erect, arising from axils as modified branches, rigid, to 2cm long, usually subtended by a small leaf, with 1-2 minute cataphylls near apex. Leaves alternate, fascicled on short shoots or scattered on long shoots, simple, narrowly-elliptic to oblong lanceolate, apex acuminate, margin entire to erose-serrate, base attenuate, 3.5-12 x 1.5-4cm, pilose, glabrescent; stipules absent. Flowers pendulous; peduncle solitary, axillary, 1-flowered, 5-9(-20)mm long, tomentose, with series of overlapping bud-scales at base, scales ciliate, ovate, c.2mm long; calyx inferior, gamosepalous, 5-partite, campanulate, persistent, accrescent, 8-10mm long, rugulose with tomentose pubescence, pale green to purplish, lobes valvate, acute, triangular, erect, c.3mm long, calyx in fruit 11-16mm long, splitting irregularly; corolla much larger than calyx, gamopetalous, 5-partite, regular, elongate-urceolate, inflated, 3.5-4cm long, 1.5cm diam. at middle, densely pilose without, magenta to red-violet, lobes short, trilobate, recurved, c.5mm long with induplicate-valvate aestivation; stamens 5, inserted at base of corolla; filaments variable in length, slightly exceeding corolla, filiform, 3-4cm long, adnate for 8mm, base pilose, glabrous above, bright pink; anthers bilocular, elliptic, longitudinally dehiscent, 2mm long, brownish. Ovary ovoid, base gibbous, bilocular, with numerous anatropous ovules attached on axile placenta; style filiform, equalling corolla, 3cm long, pink; stigma short, semicircular, slightly bilobulate, bright green. Fruit a fleshy berry, globose, 2cm diam., apiculate, pale green to yellow; seeds numerous, somewhat reniform or irregular, often flattened ventrally, 2mm diam., albuminous, testa thick, reticulate-pitted, dark brown to black. Fl. from Oct.-Jul., depending on climate; fr. Feb.-Mar.

In wet coastal mountain forest, pastures and roadsides, mostly 300-900m; Chile, from Valdivia Province s. to Chiloé Province.

Propagate from green branch cuttings, or from seed. Prefers mild, rainy climate [but not too wet]; may need protection from frost. Although it often grows relatively in the open, plants grown in shady spots produce larger leaves (Rätsch 2001; pers. obs.). Although Rätsch (2001) stated that "Up to now, it has never been cultivated or spread by man in any other place", L. pubiflora has been available in s.e. Australia for many years as an exotic ornamental shrub, although still very uncommon (pers. obs.).

Rätsch (2001) noted that two forms of this species [the only member of its genus] are distinguished by the Mapuche. The 'male' form is +-

thornless, but the 'female' form is thorny; it is the 'female' form said to bear the magical properties associated with L. pubiflora (Rätsch 2001). Sometimes confused with Dasyphyllum diacanthoides [Flotowia diacanthioides] or 'tayu', a medicinal plant from the same region (Plowman et al. 1971). However, since this plant is a member of the Compositae, this confusion should not occur when the plants are in flower (pers. obs.).

LAURUS

(Lauraceae)

Laurus azorica *(Seub.) J. Franco* **(L. canariensis** *Webb et Berth, non Willd.***; Persea azorica** *Seub.***)** – loireiro, loureiro, louro

Laurus nobilis *L.* – bay laurel, bay tree, sweet bay, laurel, Grecian laurel, lorbeer

The bay laurel holds a rather noble place in European history, and was used as a drug by cultures as early as the Mesopotamians. It has long been used to dispel evil spirits. The Greeks identified it with Apollo, the god of prophecy, poetry and healing. The herb is also dedicated to Apollo's son, Aesculapius, god of medicine. The oracular priestesses at Delphi [the 'Pythia'] were reputed by some researchers to have chewed and inhaled the smoke from the leaves of the bay [which the roof of the Delphi temple was made of], as well as other psychotropic herbs [such as **Hyoscyamus**] to communicate with Apollo (Bremness 1988; Cunningham 1994; Duke 1983; Rätsch 1992). A recent hypothesis which received much publicity suggested that the Pythia may have instead been inhaling hydrocarbon gases [such as ethylene] emitted from bedrock fissures of underground springs at the site (Ball 2001; Reese 2001). However, the evidence used to support this scenario has been comprehensively discredited (Lehoux 2007) [which did not receive the same publicity!].

Bay was also sometimes an ingredient of Greek wines [see *Methods of Ingestion*]. To the Romans, it symbolised wisdom and glory, and was woven into wreaths to crown victorious athletes or other social achievers of the time. The Romans burned their sacrifices together with bay and **Juniperus**. For many years, it was used to treat a wide variety of diseases including plague, and the fruits and leaves have been used to treat hysteria. Bay is considered narcotic, nervine, stimulant, antiseptic, digestive, balsamic, carminative, antitussive and antirheumatic. Today, it is mostly used for culinary purposes in small amounts, particularly in bouquet garni, marinades, soups and stews. The wood is used to smoke meat and cheese, and the essential oil is sometimes used as a flavouring in liqueurs (Bremness 1988, 1994; Duke 1983; Mabey et al. ed. 1990; Rätsch 1992). The essential oil of L. nobilis should not be confused with 'bay oil', which derives from **Pimenta**.

L. azorica leaf essential oil comprised 12.7% α-*pinene*, 10.3% 1,8-cineole, 0.5% *methyleugenol*, *eugenol*, *elemicin* and other compounds, in one study (Hokwerda et al. 1982). L. azorica collected from the Azores yielded 0.3-0.7% essential oil from leaves [consisting of 15-37% α-*pinene*, 9-18% β-*pinene*, 12-31% 1,8-cineole, and 2.2-14.6% trans-cinnamyl acetate as the major components, with traces of *methyleugenol*, trans-iso-*eugenol*, ledol (see **Ledum**), and many others], and 0.4-0.9% from berries [consisting of 27-45% trans-β-ocimene, 9-16% cis-β-ocimene, 12-22% α-*pinene*, and 7-13% β-*pinene* as the major components, with traces of many others] (Pedro et al. 2001).

L. nobilis leaves may yield 1-3% essential oil, comprised of c.38.6% *eugenol*, 0.3% *estragole*, acetyl-*eugenol*, 2.1-7.7% *methyleugenol*, 30-50% 1,8-cineole, 11% chavicol, 31.6% myrcene, and small amounts of *pinene*, limonene, linalool, neral, α-terpineol, geranyl acetate, geraniol and β-phellandrene. Leaves also contain the sesquiterpene lactones costunolide, artemorin, dehydrocostus lactone, verlotorin, santamarine, reynosin, zaluzanin D, 3α-acetoxyeudesma-1,4(15),11(13)-trien-12,6α-olide, and 3-oxoeudesma-1,4,11(13)-trien-12,6α-olide; as well as palmitic acid, lauric acid, oleic acid and linoleic acid. Some of the sesquiterpene lactones inhibit ethanol absorption, and have α-methylene-γ-butyrolactone [α-methylene-GBL] moieties [see *GHB* in *Chemical Index*] (Chiej 1984; El-Feraly & Benigni 1980; Hokwerda et al. 1982; Lawless 1995; Mabey et al. ed. 1990; Schermerhorn et al. ed. 1957-1974; Yoshikawa, M. et al. 2000).

Laurus nobilis is a dioecious shrub or small tree 2-20m tall, with slender glabrous twigs. Leaves 5-10 x 2-4(-7.5)cm, narrowly oblong-lanceolate, acute or acuminate, entire, glabrous, alternate, smooth, leathery, glossy on upper side, opaque on the lower, deep green, veins prominent, among which the numerous oleiferous glands are clearly visible against the light; petiole very short. Flowers actinomorphic, small, yellowish-green; inflorescence subsessile; male flowers with 6-8 stamens, all or most with 2 glands at base; anthers opening by 2 valves, introrse; perianth deeply 4-lobed; female flowers with 2-4 staminodes; ovary superior, 1-celled; style simple; stigma present. Fruit a berry, 10-15mm, ovoid, blackish when ripe.

Mediterranean region, cultivated elsewhere and naturalised in some places (Chiej 1984; Tutin et al. ed. 1964-1980). Grows best in full sun with wind protection in a rich, moist, well drained soil. Cultivate from 10cm stem cuttings or by layering in late summer; plant cuttings in heated propagator with high humidity, if in a cold climate. Gather in summer (pers. comms.).

LEDUM

(Ericaceae)

Ledum groenlandicum *Oeder* **(L. latifolium** *Aiton***; L. palustre ssp. groenlandicum** *(Oeder) Hultén***)** – labrador tea, la dee muskat

Ledum hypoleucum *Kom.*

Ledum palustre *L.* – wild rosemary, marsh rosemary, crystal tea ledum, Dutch myrte, porst, sumpforst, tannenporst, kienporst, mottenkraut, wanzenkraut, bauerkraut, senkura, senkia, synkiu, bagul'nik, puyasmes, makum

'Labrador tea' [L. groenlandicum] was used by the Kwakiutl and Salish of w. Canada, who steeped the leaves to make an intoxicating tea. The leaves also expel catarrh and treat colds, and a tea of them is used in Alaska to relieve colds and hangovers (Bremness 1994; Festi & Samorini 1996; Ott 1993). It has similar medicinal and psychotropic properties to L. palustre [see below], but is generally less potent (Buhner 1998). When smoked, the leaves act as a pleasant stimulant (Zombiebowl pers. comm.).

The Tungus of n. Siberia [including the Nannay, Udegay, Ulk and Orocci] use L. hypoleucum and L. palustre as inebriants, by heating the dried leaves in a frying pan and inhaling the fumes – the effects were said to be stupefying and analgesic (Brekhman & Sam 1967). It has been reported that the root was sometimes chewed at the same time as inhaling the fumes of the smouldering foliage. Ainu shamans use a salted tea of 'spruce', L. palustre and 'mint' [Mentha spp. – see *Endnotes*] during their shamanic curing rituals; the plant alone was used to treat dysmenorrhoea. Leaves, flowers, and/or seeds of L. palustre were once widely used in Europe in beer brewing, often with Myrica gale [see *Methods of Ingestion*, *Endnotes*]. The beer thus prepared was known as 'gruitbier' or 'gruebsing'. The Swedish Vikings were known to consume it in public festivities. L. palustre has been demonstrated to synergise with alcohol, and produce a fuller intoxication more quickly than would either taken alone. Its consumption has been suggested to have been productive of the Berserkers' rage, which is a matter of debate. Alone, the herb has effects similar to alcohol, as well as causing muscle cramps, later paralysis, and strong digestive tract stimulation (Buhner 1998; Festi & Samorini 1996; Rätsch 1992).

In n.w. Europe, L. palustre was used as an ingredient of a magic potion also containing 'hemlock' [see **Conium**], 'henbane' [see **Hyoscyamus**], 'asa-foetida' [see **Ferula**], 'saffron' [see **Crocus**], 'poppy' seeds [see **Papaver**], 'mandrake' [see **Mandragora**], a **Solanum** sp. and an Aloe sp. [see *Endnotes*]. Medicinally, L. palustre is used today as an expectorant, galactagogue, emmenagogue, diuretic, antidiabetic, abortive, antiparasitic and whooping cough treatment (Buhner 1998; Festi & Samorini 1996).

L. palustre has been suspected of producing toxic ericolin-containing honeys; however there is no evidence for the occurrence of this compound in the plant (Ott 1993).

The essential oil is believed to be the psychoactive component of Ledum spp., the activity of which has so far been mainly attributed to the sesquiterpene alcohol ledol ['ledum *camphor*'], one of the major constituents. In humans and other animals, ledol produces initial CNS-excitation, sometimes with convulsive activity and palpitations, accompanied by inebriation; later, paralysis may occur. Its effects are somewhat similar to those of *camphor*. Usually in humans the toxic symptoms only arise with larger doses, which may induce miscarriage (Buhner 1998; Festi & Samorini 1996).

L. groenlandicum foliage yielded 0.035% essential oil, containing small amounts of phenols, aldehydes, sesquiterpenes and azulene, as well as ledol (Lynn et al. 1926).

L. hypoleucum essential oil yielded 2.2% ledol [it was not made clear whether this was as % of oil, or % of plant material] (Festi & Samorini 1996).

L. palustre var. palustre yielded 0.5-1% essential oil, with 1-2.5% ledol [see comment for L. hypoleucum], as well as palustrol, myrtenal, myrcene, *estragole*, alloaromadendrene, lepadol, lepalene, isopinocamphone, germacrone, aesculetin, umbelliferone, *scopoletin*, fraxetin, hyperoside, quercetin, sterols and aliphatic monoterpenes. Aerial parts also yield coumarin glycosides – palustroside, fraxine and esculine (Buckingham et al. ed. 1994; Festi & Samorini 1996; Tattje & Bos 1981).

L. palustre var. macrophyllum essential oil has yielded 22.3% ledol [see comment for L. hypoleucum] (Festi & Samorini 1996).

Ledum palustre is an evergreen shrub, with stems up to 120cm, decumbent to erect; young twigs ferruginous-tomentose. Leaves alternate, shortly petiolate, 12-50 x 1.5-12mm, linear to elliptic-oblong, ferruginous-tomentose beneath, deflexed in winter, margins revolute. Flowers numerous, 5-merous, in terminal, umbel-like, +- corymbose racemes; pedicels 5-25mm, persistently glandular-verrucose and also often ferruginous-tomentose at first, erect in flower, deflexed in fruit; bracts scarious, decidu-

ous; bracteoles absent; sepals small, connate for most of their length; petals free, 4-8mm, obovate, white, patent; stamens (5-)8-10(-14); anthers without appendages. Ovary and capsule verrucose-glandular. Fruit a septicidal capsule; seeds with very loose testa.

In bogs, heaths and coniferous woods; n. & c. Europe, south to s. Germany, n.e. Austria and n. Ukraine, North America from Alaska south to Newfoundland (Tutin et al. ed. 1964-1980). Becoming very rare in Europe (Festi & Samorini 1996).

LEONOTIS

(Labiatae/Lamiaceae)

Leonotis dysophylla *Benth.* **(L. ocymifolia var. raineriana** *(Vis.) Iwarsson***)**

Leonotis leonotis *R. Br.* **(L. ovata** *Spreng.***)** – lion's ear, klipdagga, knoppiesdagga

Leonotis leonurus *(L.) R. Br.* **(Phlomis leonurus** *L.***)** – lion's tail, lion's ear, wild dagga, red dagga, klipdagga, dagga dagga, twalainoyani, minaret flower

Leonotis mollis *Benth.* – balm of gilead [usually applied to the unrelated Populus x candicans]

Leonotis nepetaefolia *R. Br.* **(L. kwebensis** *N.E. Br.***; L. nepetifolia** *(L.) W.T. Aiton***; Phlomis nepetaefolia** *L.***)** – lion's ear, Christmas candlestick, chandelier, cordão de São Francisco, molinillo

L. leonurus is sometimes used as a smoking herb by the Hottentot of S. Africa, when **Cannabis** or tobacco [see **Nicotiana**] are not available. The shoots and immature flower buds are picked, dried and smoked, or a resin may be scraped from the leaves and smoked with tobacco. It has also been used for recreational purposes by the Kaffirs, as well as white farmers, and its 'narcotic' properties are known in the Belgian Congo. Nama tribesmen used to chew a wad of the powdered leaf to produce the desired effects. Decoctions of the plant have been used medicinally, treating skin eruptions, haemmorrhoids, flu, coughs and colds, indigestion, headache, jaundice, partial paralysis, epilepsy and 'cardiac asthma', also acting as a purgative, anthelmintic and emmenagogue. L. leonotis is used in the same way as L. leonurus. The Suto sometimes smoke L. mollis with tobacco. Europeans in southern Africa sometimes use L. dysophylla as a nerve tonic, and L. nepetaefolia as an antispasmodic. L. microphylla is also known as 'wild dagga', 'knopdagga' and 'klipdagga' (Emboden 1979a; Watt 1967; Watt & Breyer-Brandwijk 1932, 1962), suggesting a similar usage. However, some doubt that Leonotis spp. are psychoactive at all. To support this doubt, De Smet (1998) cited an earlier researcher who noticed no effects after smoking 'several successive pipefuls' of L. leonurus. This is in conflict with many modern anecdotal reports of success [eg. see below], though it is possible that some people simply do not respond much to this drug (pers. obs.). One friend suggested from her observations that in general, women are more affected by it than men (Baill pers. comm.).

It should be said that the taste of the plant and its smoke is rather sickly and bitter [perhaps due to the bitter compound marrubiin – see below], a fact acknowledged by the Hottentot. Most people simply don't find it worth the bother, except mixed with other psychoactive herbs to mask the taste. The effect of smoking L. leonurus is rather mild for most people, though some do enjoy it for producing a light, 'playful' high. In practice it may be difficult to obtain resin by scraping the plant directly [as was mentioned above] (pers. comms.; pers. obs.). Observations by growers in New South Wales [Australia] indicate that the plant only produces useful quantities of resin in hot, dry climates, preferably over 40°C. Some claim that resin is only produced in the leaves, with larger and thicker leaves bearing more resin (Torsten pers. comm.) – however, sometimes the flower buds are sticky and thus appear to contain resin. The plant may be hand-rubbed to acquire small amounts of resin in a similar way to making hashish by the rubbing technique [see **Cannabis**]. It may be more desirable to make an extract for smoking purposes. One person described the effects of a dried alcohol extract as "like having a (small) cone [of **Cannabis**] and a (small) line of speed [some variety of *amphetamine*] at the same time. Lasts only about half an hour". Another person obtained a 'crystalline' green powder from sun-drying a liquid extract made by simply passing fresh flower buds through an electric juicer. The smoke from this extract was reportedly quite active and lacked most of the bad taste of the smoked herb (pers. comms.; pers. obs.).

L. dysophylla leaves have yielded 0.44% 8β-OH-marrubiin (Kaplan et al. 1970).

L. leonotis leaves have yielded 0.47% leonitin, a grindelane diterpenoid (Eagle et al. 1978).

L. leonurus has yielded 0.4% marrubiin, premarrubiins I & II, 0.5% compound X and 0.5% compound Y; the leaf may contain up to 19.8% resin (Rastogi & Mehrotra ed. 1990-1993; Watt & Breyer-Brandwijk 1962).

L. nepetaefolia leaves [from Trinidad] have yielded labdane diterpenoids, including nepetaefolin [major component], methoxynepetaefolin, nepetaefolinol, nepetaefuran, nepetaefuranol, leonotin, and leonotinin. Indian plants yielded nepetaefolinol as the major component, and also contained dilactone (Blount & Manchand 1980); 8β-OH-marrubiin (Kaplan et al. 1970) and the coumarin 4,6,7-trimethoxy-5-methylchromen-2-one have also been found in this species (Rastogi & Mehrotra ed. 1990-1993). Plants from Puerto Rico have shown antitumour activity (Blount & Manchand 1980).

None of the diterpenoids found in Leonotis spp. have been shown to be psychoactive, though it would seem that neither have they been adequately studied in this regard.

Leonotis leonurus is a perennial shrub to 2m tall; branches densely hairy, hairs both short and long, simple and multicellular, mostly antrorse. Leaves opposite, green, lanceolate to narrow-elliptic, sparsely hairy, 5-8 x 1-1.5cm, apex subacute, base tapering into petiole, margins irregularly toothed; petiole 3-10mm long. Inflorescence dense whorled clusters of 12 or more flowers per axil; calyx 8-10-veined, funnel-shaped, 8-10-toothed, mouth slightly oblique, tube 10-15mm long, densely shortly hairy, lobes to 1mm long, shortly and broad-triangular, +- mucronate; corolla 30-55mm long, bright orange, 2-lipped, lower lip 3-lobed, upper lip concave, longer than lower; stamens 4, ascending upper lip of corolla; anther loculi divergent. Ovary deeply 4-lobed; style gynobasic; stigma reduced to a tiny tooth. Mericarps +- smooth. Fl. all year.

Native to S. Africa; a garden escapee in coastal areas of Victoria, New South Wales and Western Australia [Australia]. Common in cultivation (Harden ed. 1990-1993).

Propagate these attractive plants from seed in winter, or from cuttings in spring. Provide with full sun, watering deeply and infrequently. Very hardy in Melbourne, Australia (pers. obs.).

LEONURUS

(Labiatae/Lamiaceae)

Leonurus cardiaca *L.* – common motherwort, lion's ear

Leonurus heterophyllus *Sweet* **(L. artemisia** *(Lour.) S.Y. Hu***)** – chong wei, i-mu-tsao, yi-mu-cao, yet-mo-juo

Leonurus sibiricus *L.* – Siberian motherwort, marihuanilla, honeyweed, i-mu-tsao, yi-mu-cao

'Motherworts' have long been used for their relaxing and therapeutic properties. Culpepper stated "there is no better herb to take melancholy vapours from the heart, to strengthen it, and make a merry, cheerful, blithe soul." Some early herbals also recommended it against 'wicked spirits' (Ody 1993). L. cardiaca is used to relieve anxiety in new mothers. It is sedative, calms tachycardia, lowers blood pressure, treats menstrual pain and irregularity, contracts the uterus after birth, reduces muscle spasms and reduces blood fat levels (Bremness 1994; Chevallier 1996; Mabey et al. ed. 1990; Pendell 1995; Polunin & Robbins 1992).

L. heterophyllus and L. sibiricus are often used interchangeably in

TCM – they are considered pungent, bitter and cold in energetics, with an affinity for the liver and heart meridians. They have the same gynaecologic applications as L. cardiaca, and are used [in a 15-60g deoction] to stimulate circulation and respiration, cause vasodilation, clear clots and disperse phlegm. The seeds, known as 'huang wei zi', have similar uses to the herb, as well as brightening tired or sore eyes (Bremness 1994; Hsu et al. 1986; Huang 1993; Reid 1995), and acting as a diuretic and aphrodisiac, increasing sperm count (Perry & Metzger 1980).

Since at least 1918, L. sibiricus has been smoked in Malaya when **Cannabis** was not available. In some areas of Chiapas, Mexico, it is known as 'marihuanilla', and is smoked for its sedative effect. It is also used in a tincture to treat rheumatic fever (Diaz 1979; Emboden 1979a). The effects of Leonurus spp., smoked in large joints, are somewhat similar to those of smoked **Cannabis** leaf (pers. comms.; pers. obs.). Dried, powdered leaves and flowering tops of L. sibiricus [c.500mg or ¼tsp for a starting dose] may be taken orally with fruit juice for mild psychotropic effects lasting 2-3hrs; blending with **Cannabis** and/or **Tagetes** is reported to enhance the effects (Lazar 2002).

L. cardiaca has yielded 0.0068% of the guanidine alkaloid leonurine when flowering [diuretic, stimulates skeletal muscle, followed by neuromuscular depression], 0.055% stachydrine, leocardin, 0.001% of the labdane diterpene 10-acetoxypregaleopsin, the iridoid glucosides leonuride [ajugoside] and ajugol, flavonoids [such as marrubiin (see **Leonotis**), rutin, quinqueloside, quercitrin, isoquercitrin, hyperoside, genkwanin, 5,4'-dihydroxy-7-methoxyflavone, *apigenin*-derivatives and kaempferol-3-O-D-glucoside] and vitamin A (Buckingham et al. ed. 1994; Gulubov & Chervenkova 1971; Huang 1993; Kartnig et al. 1985; Ody 1993; Papanov et al. 1998a, 1998b; Rastogi & Mehrotra ed. 1990-1993; Schermerhorn et al. ed. 1957-1974).

L. heterophyllus has yielded 0.01% leonurine, stachydrine, leonuridine, leonurinine, lauric acid, oleic acid, vitamin A and fatty oils (Hsu et al. 1986; Huang 1993).

L. sibiricus has yielded 0.02-0.04% leonurine, stachydrine, leonuridine, leonurinine, cycloleonurinin, leosibirin, isoleosibirin, leosibiricin, rutin, arginine, stachyose, 4-guanidino-1-butan-ol, 4-guanidinobutyric acid, 12,13-epoxyoleic acid, palmitoleic acid, linoleic acid, oleic acid, eicosanoic acid, benzoic acid, lauric acid, sterol and vitamin A (Buckingham et al. ed. 1994; Hsu et al. 1986; Rastogi & Mehrotra ed. 1990-1993).

Leonurus sibiricus is an erect annual or biennial herb to 180cm tall; stems obtusely quadrangular, furrowed, usually softly retrorse-pubescent. Leaves 3.8-10cm long, deeply 3[or more]-parted, palmatipartite with linear incised segments, glabrous or nearly so above, pale and +- pubescent on the veins beneath, upper floral leaves often entire; nerves strong below; petioles up to 5cm long. Inflorescence of axillary spiked whorls; bracts subulate, ½-fully as long as the calyx tube; calyx 6-8mm long, turbinate, glabrous or slightly pubescent, 5-lobed, lobes spinescent from a triangular base, tube weakly 10-nerved, 5mm long; corolla pink-reddish, to 13mm long, tube roughly equalling the limb, annulate within, upper lip obovate, galeate, entire, pubescent, lower lip roughly equalling the upper, 3-lobed, the middle lobe subcordate, the 2 lateral lobes smaller, rounded; stamens 4; anthers conniving, cells transverse. Nutlets 2.5mm long.

Waste places; tropical Asia, plains of India, Africa, America (Gleason 1952; Kirtikar & Basu 1980), naturalised weed in Australia [N.S.W.] (Hnatiuk 1990).

LEPTACTINIA

(Rubiaceae)

Leptactinia densiflora *Hook. f.* – karo-karoundé, nami, wata, tangboruku

The leaves of this African shrub contain an essential oil, which is used in perfumery. Its wood might be useful in craft [such as for making musical instruments, snuff boxes, hairpins and combs], as is the wood from L. senegambica (Burkill 1985-1997; Usher 1974). This plant is of greater interest here due to its chemistry.

L. densiflora leaves have yielded 0.5% *leptaflorine* [tetrahydroharmine], which was first found in this plant (Paris & Caiment-Le Blond 1955); roots have yielded 0.18% crude alkaloids, including *tetrahydroharman* (Paris et al. 1957). The root bark has also yielded 2% catechuic tannin, and a small amount of flavones. Flower essential oil contains c.32% phenolic acids. Trunk bark and root bark of L. senegambica have also tested positive for alkaloids (Burkill 1985-1997).

Leptactinia densiflora is a large, bushy shrub; branchlets densely or sparingly pilose, or nearly glabrous. Leaves broadly elliptic to obovate, obtuse or cuneate at base, +- acuminate at apex, more than 7.5-20 x 3-11cm, with 7-10 main lateral nerves on each side of the midrib, usually with long weak hairs and tufts of shorter hairs by the midrib and nerves beneath; petioles more than 5mm long. Inflorescence a terminal corymb; white fragrant tubular flowers 2.3-7.6cm long, velvety outside, in dense heads; calyx lobes contorted in bud, 1.3-3cm long; corolla tube (2-)4-8(-10.5)cm, lobes (1.2-)1.8-3(-3.5)cm long; anther cells not divided into compartments. Ovary 1-2-celled; ovules several to numerous; style included in corolla tube, with 2 recurved spreading arms. Fruits black, ribbed and wrinkled, 1.3cm diam., crowned by the long calyx.

Sierra Leone, Liberia, Ivory Coast, Ghana, s. Nigeria (Hutchinson & Dalziel 1954-1972).

LESPEDEZA

(Leguminosae/Fabaceae)

Lespedeza bicolor *Turcz.* – bicolor Lespedeza, bush clover

Lespedeza bicolor var. japonica *Nakai* – bicolor Lespedeza, bush clover, wild stem, hu chih tzu

Over much of the world, Lespedeza spp. are used as a protein-supplement forage for stock animals, and for green manure, as well as being grown to prevent soil erosion (Allen & Allen 1981). L. bicolor var. japonica is reportedly used in Brazil in a similar way to 'jurema' [see **Mimosa**] (Der Marderosian 1967; Watt 1967). In N. America, L. bicolor is used as an analgesic, as is L. capitata (Ott 1993). The Kiowa give a leaf tea of L. capitata as a tonic for the sick, and the Omaha and Ponca used the herb as a 'moxa' [see **Artemisia**] for neuralgia and rheumatism (Kindscher 1992).

Recently, red autumn leaves of L. bicolor [cultivated in US] were reported to be useful as a component of an ayahuasca analogue [see *Methods of Ingestion*]; c.30g or more of these leaves, with an MAOI, was sufficient to produce the desired effects (Ringworm pers. comm.).

L. bicolor var. japonica from Japan has yielded *tryptamine* alkaloids [0.068-0.106% crude alkaloids from leaf, 0.206% from root bark]. Leaves contained *DMT* [major alkaloid – 0.25% in one test], *5-methoxy-DMT*, *bufotenine*, and 0.035% *lespedamine* [1-methoxy-*DMT*]; root-bark contains these alkaloids in greater amounts, as well as *DMT* N-oxide and *5-methoxy-DMT* N-oxide (Goto et al. 1958; Morimoto & Matsumoto 1966; Morimoto & Oshio 1965). Independent TLC-analysis of L. bicolor var. bicolor has found alkaloids to be in greater concentration in the seeds; no alkaloids were detected in foliage of the 1st year's growth (Trout ed. 1997d). In a broad alkaloid screening, L. bicolor roots [from US, harv. Sep.] tested negative for alkaloids, and seeds tested positive only in preliminary tests; the confirmation tests were negative (Fong et al. 1972). Leaves also contain the carbohydrate d-pinitol; unripe seeds contain the amino acid canavanine [see **Canavalia**], as well as orientin, homoorientin, quercetin, isoquercetin, kaempferol [MAOI (Sloley et al. 2000)], trifolin, and 6 other flavonoids (Glyzin et al. 1971; International... 1994).

L. capitata has yielded a great array of flavonoid glycosides [including kaempferitrin and iso-orientin], as well as the alkanes n-pentacosane, n-hentriacontane, n-hexacosane and n-tritriacontane (Linard et al. 1982; Tin-Wa et al. 1969). In a broad alkaloid screening, root, stem, leaf and fruit tested negative (Fong et al. 1972).

L. cuneata leaves have yielded the C-glycosylflavones isoorientin, isovitexin, vicenin-2, lucenin-2, and the C-glycosylflavonoid 6,8-di-C-pentosyl-*apigenin* [a feeding stimulant for larvae of Eurema hecabe mandarina, a butterfly which uses this plant as its host] (Numata et al. 1980).

L. cyrtobotyra root bark has yielded isoflavanones [lespedeol A, lespedeol B] and pterocarpans [lespein, lespedezin]; stem bark yielded chalcones [lespeol, xanthoangelol]; heartwood yielded isoflavonoids [daidzein, dalbergioidin, genistein, haginins A-D, lespedeol C, 3,9-dihydroxypterocarp-6a-en, 2-(2,4-dihydroxyphenyl)-6-OH-benzofuran], as well as isoliquiritigenin (Miyase et al. 1980, 1981), which has shown MAOI properties (Pan et al. 2000).

Canavanine has also been found in L. macrocarpa, L. sericea and L. tomentosa (Bell et al. 1978); alkaloids were not found in leaves and stems [harv. Mar.-Jul.] of L. hirta, L. sericea, L. striata, or L. stipulacea growing in New Zealand (White 1951).

Lespedeza bicolor is an erect shrub to 1m, woody at base; stems stout and erect. Leaves mostly trifoliate; leaflets ovate, rounded or emarginate at tip, petioluled, pinnately veined; stipules linear or ovate-lanceolate, awl-shaped, setaceous, persistent. Flowers small, purple, in conspicuous clustered racemes; 2 kinds of flowers – petaliferous (papilionaceous) and apetalous, the apetalous fertile; peduncles 1-3cm long; bracts linear, small, subtending each pedicel, persistent; pedicels often 2-3 together, long and slender, bearing 1 or 4 persistent bracteoles at base of calyx; calyx campanulate, cylindric, 5-lobed, acuminate but not setaceous, calyx teeth ovate-lanceolate; standard oblong-obovate, clawed; wings oblong, slightly curved, clawed; keel petals obovate, incurved; stamens diadelphous, grouped 9 and 1; anthers uniform. Ovary sessile or stalked, 1-ovuled; style filiform, incurved; stigma small, terminal. Pod oval-orbicular, sessile or short-stalked, compressed, reticulate, tipped with remnant style, indehiscent; seed 1, flat, rounded. Fl. Jul.-Sep., fr. Oct.

In brushland; n. China, Manchuria, Japan and Hawaii.

L. bicolor var. rosea is found in the US (Allen & Allen 1981; Steward 1958).

Cultivate from seed; scarification is beneficial, but seed damages easily, and clean seed should not need it; may be inoculated with bean inocu-

lant, but can germinate and grow without; sow early spring, c.6mm deep, germinates 1-3 weeks. Grow in full sun, almost any soil; drought resistant (pers. comm.).

LICARIA

(Lauraceae)

Licaria cannella *(Meisn.) Kosterm.* **(Aydendron cannella** *Meisn.***)**
Licaria puchury-major *(Mart.) Kosterm.* **(Acrodiclidium puchury-major** *Mez.***; Nectandra puchury-major** *Nees***; Ocotea puchury-major** *Mart.***)** – pixuri, puchuri, puchury, puchery, puchyry, picheri

The seeds of L. puchury-major, known as 'puchuri', are widely used in Brazil as a sedative tranquilliser, and to treat intestinal disorders. A dose is prepared by taking one seed [weighing c.4-5g], powdering it, and infusing in 70-100ml boiling water, in a wrapped, sealed container. This preparation is referred to as 'abafado' (Carlini et al. 1983). The seeds are readily harvested from the rainforest floor as they strongly resist decomposition, and can thus be easily picked out from other rotting vegetable matter (Himejima & Kubo 1992).

L. aritu [also from Brazil] contains the neolignans licarin-A and licarin-B in the wood; licarin-A is almost identical to dehydrodiiso-*eugenol*, except for its differing optical activity (Aiba et al. 1973).

L. cannella [again from Brazil] has yielded *elemicin*, *dillapiole*, sitosterol and neolignans [canellins A-C], all from the trunk wood (Giesbrecht et al. 1974).

L. puchury-major seed essential oil [yield 1.8%] is rich in phenylpropenes – 36-51.3% *safrole*, 3.3-14% *eugenol*, 2.9% *methyleugenol*, and *anethole*; as well as 25% 1,8-cineole, 5.4% eucalyptol, 8.9% lauric acid, 8.6% α-terpineol, 4-terpineol, geraniol, limonene, γ-terpinene, linalool, caryophyllene, and lauric acid. Essential oil from the leaves contained 21.7% *safrole*, 1.7% *eugenol*, 47.6% eucalyptol and 11.7% α-terpineol; branchwood essential oil contained 20.1% *safrole*, 61% *eugenol*, 10.8% eucalyptol and 6.8% α-terpineol. The non-essential oil fraction of an aqueous seed preparation showed depressant activities in mice [administered i.p.] different to those caused by the less potent essential oil fraction (Carlini et al. 1983; Da Silva et al. 1973; Himejima & Kubo 1992).

Licaria puchury-major is a tree with straight branchlets, glabrous, bark very aromatic. Leaves sparse to subopposite, glabrous, elliptic, +-120 x 55mm, base obtuse to subacute, apex shortly caudate-acuminate, loosely prominently reticulate on both sides, especially beneath; petioles to c.20mm long. Inflorescence axillary, (sub)few-flowered, racemose-paniculate, base subfasciculate-divided, moderately tomentellous, inflorescence-leaves short, pedicels barely present; flowers tomentellous, 4mm long; perianth tube largest, ellipsoid, apex not constricted, lobes long, 4, scale-shaped, ovate, obtusely acute. Male parts in 2 exterior perianthiform series, sterile, perianth lobes subequal in 2 exterior series, foliaceous; 1/3 of biglandulose base fertile, 1/4 entirely abortive; filaments introrse, thick, fleshy, glabrous, free, apex not constricted; anthers 2, shortly separate, introrse, apex obtuse. Ovary subsuperior, glabrous, ellipsoid; style very short, conical, terete, gradually attenuate, glabrous; stigma slightly obtuse. Berry totally included in cupule when immature, adult oval, cupule doubly high, mostly c.5cm long; cupule large, thick, rugulose, sub-saucer-shaped, obscurely double-marginate.

In forests; n.w. provinces of Brazil, upper Amazon, near Tabatinga, Rio Negro (Garke & Urban 1889).

LIMONIA

(Rutaceae)

Limonia acidissima *L.* **(L. crenulata** *Correa***; Feronia elephantum** *Correa***; F. limonia** *(L.) Sw.***; Schinus limonia** *L.***)** – elephant apple, wood apple, monkey fruit, curd fruit, citron des mois, kapitthah, velagapandu, bela, katbel, kaith, kavita

In India, this plant has a variety of medicinal applications. The leaves treat epilepsy; the root is purgative, diaphoretic, and treats colic; and the fruits treat indigestion and persistent fevers, and prevent contagion of smallpox. The fruit is also considered tonic, and an antidote to various poisons (Kirtikar & Basu 1980; Nadkarni 1976). In Thailand, the fruit juice is used as a yellow ink, and a yellow powder made from the stems [called 'tanaka'] is used as a cosmetic face paint. A water soluble gum from the tree ['feronia gum', or 'velampisini'] is used in the manufacture of glue, varnish and water paints. The tree is also cultivated for its aromatic fruit, which may be eaten raw or made into a variety of beverages and desserts (Usher 1974; Zarga 1986).

L. acidissima fruit has yielded acidissiminol, acidissiminin epoxide and N-benzoyl-*tyramine* [see **Casimiroa**] (Ghosh et al. 1991). Root bark has yielded the coumarin dihydrosuberenol (Ghosin et al. 1982). Stem bark has yielded 0.045% *DMT*, 0.0027% N-acetyl-*N-methyltryptamine*, 0.0035% 2-methyl-THβC, 0.0004% 3-formylindole, 0.0027% tanakine, 0.003% tanakamine, 0.00025% tembamide, 0.0005% N-(p-OH-β-phenethyl)-p-OH-cinnamide, 0.004% 4-MeO-2-quinolone, 0.001% 4-MeO-1-methyl-2-quinolone, 0.0025% 4,8-dimethoxy-2-quinolone [edulitine], 0.0003% physcion [a laxative anthraquinone], 0.0017% syringaresinol [a cytotoxic lignan], and limonoids [0.0007% acidissimin, 0.0017% obacunone, limonin and methyl-deacetylnominilate]. The plant has also yielded other coumarins, including umbelliferone, geranyl umbelliferone, marmesin, xanthotoxine, luvangetin, suberosin, epoxysuberosin, suberenol, crenulin and crenulatin; as well as β-sitosterol and lupeol (MacLeod et al. 1989; Zarga 1986); leaf essential oil contains *estragole* (Harborne & Baxter ed. 1993).

Limonia acidissima is a spiny, glabrous shrub or small tree; spines sharp, 1.2-2.5cm long. Leaves alternate, pinnate, 2.5-10cm long; leaflets in 2-4 pairs, 2.5-5 x 1.2-2.5cm, trapezoid-ovate, obtuse, rarely acute, notched at apex, crenulate, glabrous, base cuneate; petiole and rachis jointed, the former narrowly, the latter very broadly winged; joints of rachis obovate-oblong, crenulate. Flowers in umbelliform, often leafy racemes; peduncles 2-3 together from axils of fallen leaves; pedicels slender; calyx small, glandular, lobes 4, broadly ovate, acute; petals 4, glandular, imbricate, 6mm long, elliptic-oblong; stamens 8, free, subequal; filaments linear-subulate; anthers cordate or linear-oblong; disc stipitiform. Ovary papillose, 4-celled; ovules 1-2 in each cell; style stout; stigma obtuse or capitate. Berry c.1.2cm diam., globose, 1-4 seeded, very acidic; seeds embedded in mucilage.

W. & s. India, Punjab, n.w. Himalaya, Simla, Kumaon, Bihar, Bengal, Assam, Burma, Siam, Cambodia, Laos, Yunnan, Malaya, Java (Kirtikar & Basu 1980).

LOBELIA

(Campanulaceae/Lobeliaceae)

Lobelia alata *Labill.* – angled lobelia
Lobelia cardinalis *L.* **(Dortmannia cardinalis** *(L.) Kuntze***)** – cardinal flower, common red lobelia
Lobelia chinensis *Lour.* **(L. caespitosa** *Blume***; L. campanuloides** *Thunb.***; L. erinus** *Thunb.***; L. radicans** *Thunb.***)** – ban bian lian
Lobelia deckenii *(Asch.) Hemsl.* – Tanganyika lobelia, giant lobelia
Lobelia excelsa *Bonpland*
Lobelia inflata *L.* – Indian tobacco, wild tobacco, lobelia, poke weed, emetic weed, asthma weed, gagroot
Lobelia laxiflora *Kunth* **(Tupa laxiflora** *(Kunth) Planch. et Oerst.***)** – chilpanxóchitl
Lobelia pyramidalis *Wall.* – rato phul ['red flower'], deu nigalo ['bamboo of the gods']
Lobelia quadrangularis *R. Br.* – jarrinymawu ['cave dweller']
Lobelia syphilitica *L.* – blue cardinal flower, giant lobelia
Lobelia spicata *Lam.*
Lobelia tupa *L.* – tupa, tabaco del diablo
Lobelia spp.

L. inflata is used as a medicine and ritual smoking herb by many native North American groups. Although today in herbal medicine many consider it too toxic to use, low doses can be used safely with care and in moderation. The Cherokee use it to break tobacco addiction [see **Nicotiana**], to treat asthma and sore throat, and as an emetic; it is also applied as a poultice to sores and aches. The Cherokee also use L. spicata to treat shaking and trembling. The Crow used L. inflata ritually, and the Mesquakie and Pawnee used it in love magic. The Penescot used it to induce sweating and vomiting, to drive out evil spirits. It may be smoked to improve mental clarity and relax the body, as well as to treat asthma and bronchitis. The plant is also taken internally as a decoction, though it is potentially more toxic via this route (Bremness 1994; Hamel & Chiltoskey 1975; Hutchens 1973; Kindscher & Hurlburt 1998; Ott 1993; Rätsch 1992). In more recent times, L. inflata has been explored as a mild psychotrope in smoking mixtures amongst curious psychonauts (Rätsch 1990; Siegel 1976).

The Cherokee also use L. cardinalis and L. syphilitica interchangeably – a root tea treats worms and stomach troubles, and a leaf tea treats fever, rheumatism, colds and sores. L. cardinalis is also used as an antispasmodic, and acts as a nervine. These two species are also used by the Mesquakie in love magic. The Iroquois use L. cardinalis as a kind of panacea, and often mix it with other ingredients to strengthen their effects; they consider it to protect against witchcraft, treat depression, and render one attractive to the opposite sex. They also use a root decoction of L. syphilitica to treat syphilis, fluid retention, and diarrhoea [in small doses for the latter]. The powdered root was put in the bed of quarrelling couples to rekindle their love. In Mexico, L. laxiflora root is used as a respiratory stimulant and anti-spasmodic, and has *lobeline*-like effects [see below]. In the Chilean highlands, the Mapuche smoke L. tupa ['tobacco of the devil'] to produce a narcotic or even visionary stupor. The Mapuche also press the milky sap from the leaves or roots, to apply externally to headache and toothache (Bremness 1994; Emboden 1979a; Hamel & Chiltoskey 1975; Heffern

1974; Rätsch 1992). Other reports of Mapuche shamans using tobacco [either smoked, snuffed or chewed] as one of their most important 'narcotic' plants during curing ceremonies (eg. see Plowman et al. 1971) most likely also refer to L. tupa, rather than **Nicotiana** (pers. obs.).

In TCM, L. chinensis leaves and stems are used as a hypotensive, diuretic, respiratory stimulant, antibacterial, and to stimulate bile secretion (Huang 1993). They may be used also for similar effects to other species such as L. inflata (pers. obs.). In India, L. excelsa is smoked by poor people. L. nicotianifolia is used to treat asthma, scorpion stings, and as an antiseptic, but it is more commonly used as a poison – as little as 1 drachm [1.8g] of the dried leaves is said to produce death (Chopra et al. 1965). In Nepal, L. pyramidalis may sometimes be used to transform water into 'amrita' (Müller-Ebeling et al. 2002). In northern Australia, the Ngarinyman chew dried L. quadrangularis as a 'bush tobacco' [see **Nicotiana**]; nowadays, it is often used mixed with commercially-available chewing-tobacco, and some ash made from the bark of Eucalyptus camaldulensis (Smith et al. 1993). In S. Africa, L. pinifolia root is used as a diuretic, and to treat rheumatism, gout, and skin diseases; it is also credited with stimulant and diaphoretic properties (Watt & Breyer-Brandwijk 1962). The giant L. gibberoa bears a latex, with a smell described as 'nauseating', which can cause violent emesis from ingestion of very small quantities (Watt & Breyer-Brandwijk 1962).

Lobelia spp. all seem to have similar chemistry and properties. Common to the genus is the alkaloid *lobeline*, which has a *nicotine*-like action, with only 1/5th-1/20th of the potency. The herbs are either smoked, steeped in water [1 tab. herb or more to 1 pint of water] or lightly decocted. The tea has an acrid taste which may cause prickling sensations in the mouth and throat, and smoking can cause headache. The effects, at low doses, are a short-lived mild stimulation, euphoria, and relaxation. Higher doses are more narcotic, and may be accompanied by nausea, vomiting, sweating, trembling, paralysis, pain, hypothermia, diarrhoea, dilated pupils, incoordination, confusion, and rapid or irregular pulse. Severe cases of poisoning may result in convulsions, coma and death from respiratory paralysis (Foster & Caras 1994; Huang 1993; Turner & Szczawinski 1991; pers. obs.). Grubber (1973) claimed that the seeds are the most potent part of these plants.

L. alata gave a positive result in an alkaloid screening (CSIRO 1990); when smoked, it had similar effects to L. cardinalis or L. inflata (Torsten pers. comm.).

L. cardinalis has yielded 0.71% *lobeline*, as well as lobelanidine and 2 unidentified alkaloids (Krochmal et al. 1972b)

L. deckenii has yielded *lobeline* (Watt & Breyer-Brandwijk 1962).

L. inflata [consisting of flowering and fruiting aerial parts] has yielded 0.36-2.38% *lobeline* (Krochmal et al. 1972a), as well as lobelinine, lobelanine, lobelanidine, isolobinine, meso-lobanine, meso-lobelanidine, isolobilanidine, lelobanidine, norlelobanidine, lobetidine, lobinanidine, lobinine, allosedamine, norallosedamine, sedinine, lobetyol, lobetyolin, 8-ethylnorlobelol, (+)-8-phenylnorlobelol, 8,10-diethyllobelidiol, 3-OH-3-phenylpropanoic acid, 8-methyl-10-ethyllobelidiol, and 8-methyl-10-phenyl-lobelidiol (Bruneton 1995; Buckingham et al. ed. 1994; Krochmal et al. 1972b; Morton 1977; Rastogi & Mehrotra ed. 1990-1993). *Lobeline* content was, on average, highest in cultivated plants, though one wild plant analysed gave the highest yield reported [2.38%]. Cultivated plants also tended to be larger than wild plants (Krochmal et al. 1972a).

L. portoricensis leaves [from flowering plants] yielded c.1.25% alkaloids, with a *lobeline*-like alkaloid, portoricin, as the major component; in animals, portoricin acted as a respiratory stimulant and anticholinergic (Meléndez et al. 1967).

L. puberula has yielded c.1% *lobeline*, as well as lobelanidine and 2 unidentified alkaloids (Krochmal et al. 1972b).

L. purpurascens from Queensland, Australia [harv. Mar. & Nov.] tested strongly positive for alkaloids (Webb 1949), and contains *lobeline*. The plant is strongly emetic (Cribb & Cribb 1981).

L. syphilitica has yielded 0.49% *lobeline*, as well as lobelanidine, and 2 unidentified compounds, one of them an alkaloid (Krochmal et al. 1972b).

Lobelia inflata is an erect herb, stems usually branched, villous, up to 1m tall. Leaves alternate, exstipulate, sessile or subsessile, ovate-oblong to oblong-obovate, 5-8 x 1.5-3.5cm, obtuse or acute, +- serrate, usually pubescent. Racemes terminating the branches, 10-20cm long; lower bracts foliaceous, the upper gradually reduced; pedicels 3-8mm long, glabrous or puberulent, bracteolate at base; flowers 7-10mm long, irregular, epigynous, gamopetalous, 5-merous; sepals linear, 3-5mm long; corolla blue or white, split to base along dorsal side, 2-lipped, 2 lobes of upper lip usually erect, the lower lip pubescent, with 3 spreading lobes; stamens 5, inserted at very base of corolla, alternate with corolla lobes, +- protruding through the cleft corolla, shorter than or exceeding corolla tube; anthers united into a tube around style, usually coloured, lower 2 bearded at apex. Ovary 2-celled; hypanthium much inflated in fruit. Fruit a capsule, opening apically; seeds many. Fl. Jul.-Oct.

Open woods in moist or dry soil, sometimes a weed of gardens or lawns; eastern US (Gleason 1952).

Sow seed where they are to grow early in spring, after the last frosts; in very cold areas, start inside in flats. Sprinkle seed on ground and rake lightly. Enjoys plenty of sun, and adequate [but not excessive] water; does not respond well to high-humidity conditions. Harvest when in flower (Krochmal et al. 1972a; Torsten pers. comm.).

LOLIUM including some ACREMONIUM endophytes

(Gramineae/Poaceae)

Lolium perenne *L.* **(L. brasilianum** *Nees***; L. canadense** *Bernh. ex Rouville***; L. marschallii** *Steven***; L. multiflorum** *Lam.***)** – perennial rye grass

Lolium temulentum *L.* **(L. arvense** *With.***; L. giganteum** *Roem. et Schult.***; L. maximum** *Willd.***; L. speciosum** *Stev. ex M. Bieb.***; Craepalia temulenta** *(L.) Schrank***)** – darnel, bearded darnel, drake, drunken rye grass, thyaros ['plant of frenzy'], aira, eaver, ivray ['inebriating'], cizana, borrachuela ['drunkenness'], taumellolch ['delirium grass'], cheat, cockle, zawan, tares, zizanion

(Clavicipitaceae/Balansiae)

Acremonium lolii *Latch., Christensen et Samuels* **(Neotyphoideum lolii** *(Latch et al.) Glenn et al.***)**

Acremonium spp.

'Darnel' [L. temulentum] has an age-old reputation for causing intoxications in both humans and animals, though some crops are non-toxic. People throughout history have occasionally become intoxicated by darnel grains baked into bread, or from the barley in beer-brewing being contaminated with darnel. Such contaminated barley is said to produce a beer that is "very intoxicating" and "unusually and even dangerously heady". Three different recipes for witch's flying potions contain darnel in their ingredients. Rumour has it that in Lebanon, a mystic group living in the mountains make a water infusion of darnel, to induce "religious ecstasy". In the Chiquian valley of Peru, L. temulentum seeds are known as 'cizana', and are added to the fermented chicha brew [see *Methods of Ingestion*] to increase its intoxicating potency. In the Canary Islands, darnel is used as a tranquilliser (Bacon 1995; Duke 1983; Gardner & Bennetts 1956; Ott 1993; Samorini 2001). L. temulentum infected with ergot [see **Claviceps**] was suggested as a possible ingredient in the Eleusinian kykeon (Wasson et al. 1978). The 'zizanion' referred to in the Bible [Matthew 13] as a weed of wheat plantations has been translated as 'tares', 'darnel' or simply 'weed', and is believed by many researchers to represent L. temulentum, though another weed of wheat fields, Cephalaria syriaca, has also been proposed as a possible identity. Both also share the name 'zawan' in Jordan and Syria (Musselman 2000).

Consumption of L. temulentum seed can cause dizziness, headache, tremor, weakness, gastrointestinal disturbance, and a delirious state accompanied by visual and auditory phenomena. Toxic doses may cause convulsions, paralysis and even death, though death in humans is very rare. L. perenne can cause similar symptoms; it also has detergent, oestrogenic, antigangrene, antiperiodic and sometimes antibiotic actions, also relieving diarrhoea. In animals, symptoms may include incoordination, head shaking, and collapse, effects which are only temporary. Seeds of these two grasses are not life-threatening in moderate amounts (Cheeke 1995; Chopra et al. 1965; Duke 1983; Gallagher et al. 1984; Gardner & Bennetts 1956; Pammel 1911; Watt & Breyer-Brandwijk 1962). However, some state that Lolium spp. have 'no pharmacological activity' themselves, and that any psychotropic effects experienced would be due to infection of the grasses by **Claviceps** ergot, or other endophytes with which they are frequently infected [see below] (Wasson et al. 1978; Samorini 2001).

Intoxicating properties of darnel are most likely due to compounds formed by the fungi living symbiotically in most examples of L. temulentum, long believed to be an Acremonium sp. Recently, strains of Neotyphoideum occultans have been isolated from specimens of L. temulentum. Neotyphoideum spp. are asexual forms of Epichloë spp., closely related to Acremonium spp. L. perenne, which is toxic to livestock [causing 'rye-grass staggers'], supports the endophyte Acremonium lolii [now regarded as Neotyphoideum lolii]. These fungi have a protective rather than a deleterious effect on the grass they inhabit. The loline alkaloids [see below] were long believed to be formed by the host grass in response to endophyte infection (Casabuono & Pomilio 1997; Freeman & Ward 1902; Moon et al. 2000); however, it now appears that these compounds can also be produced by the endophytes themselves [see **Festuca**] (Blankenship et al. 2001). For more discussion of Acremonium, Epichloë, and Neotyphoideum endophytes, see **Stipa** and **Festuca**.

In Western Australia, L. rigidum ['annual ryegrass', 'Wimmera ryegrass'] is a prominent pasture grass, and has caused poisoning in stock animals. Symptoms may be noted within 2 days to 12 weeks after feeding on the grass. "The disease is characterised by staggering and convulsions and affected animals collapse, convulse for some minutes then may regain their feet and stagger away with a stiff-legged 'rocking horse' gait".

These symptoms are most noted when animals are disturbed or forced to move, and although they often recover after a few minutes of apparent intoxication, a mortality rate of up to 53% in sheep and 45% in cattle has been recorded. Toxicity is believed to be due to infection by nematodes [Auguina lollii] which hitch a ride on the growing plant, later eating into developing flowers, where they develop into adult worms and lay their eggs. The nematode is host to a yellow, slimy bacteria [a Corynebacterium sp.], which develops fully in the flowering plant, often killing the nematode in the process. It is uncertain which organism is the cause of the toxicity (Pearce et al. 1974).

L. cuneatum has yielded loline, norloline, N-methylloline, N-formylloline, N-formylnorloline and N-acetylloline (Petroski et al. 1989).

L. perenne has yielded *harman* and *norharman* (Allen & Holmstedt 1980). When infected with Acremonium lolii it has yielded 0.0005-0.004% peramine [a pyrrolopyrazine alkaloid; insect feeding deterrent, tremorgen], perloline [mildly toxic, but rapidly destroyed metabolically after administration], 0.0005-0.001% lolitrems A, B, C, D and E [indole isoprenoid diterpenoids; tremorgens], paxilline [precursor to lolitrem B], 13-desoxypaxilline, paspaline [an indole-diterpenoid], terpendole M [an indole-diterpenoid; tremorgen], lolitriol, α-paxitriol and 0.0005% ergovaline [reduces prolactin levels]. Lolitrem B content is highest in leaf sheaths, and lowest in blades of A. lolii-infected plants. **Penicillium** spp. yielding tremorgens such as janthitrem B have been found growing on decaying plant matter in L. perenne pastures, and may complicate the observed toxicology amongst stock animals (Bush & Jeffreys 1975; Cheeke 1995; Gallagher et al. 1984; Gatenby et al. 1999; Porter 1995; Rowan et al. 1986; Watt & Breyer-Brandwijk 1962). As L. multiflorum, it has yielded octopamine, and the *phenethylamine*-conjugate annuloline (Lundstrom 1989); the roots of germinating seedlings have yielded annuloline, between the 6th and 14th day (O'Donovan & Horan 1971). It is often infected by strains of the endophyte Neotyphoideum occultans (Moon et al. 2000).

L. temulentum caryopses have yielded 0.11% alkaloids, with 0.05% loline, 0.06% temuline [narcotic, mydriatic], temulentic acid and temulentine [a decomposition product of the former – both can produce vomiting and paralysis of the brain, spinal cord and heart nerves]. Stems, leaves and peduncles have yielded 0.019% alkaloids, consisting of 0.003% perloline, 11-β-OH-gibberellin A, fructose and fructosan (Buckingham et al. ed. 1994; Chopra et al. 1965; Dannhardt & Steindl 1985; Ott 1993; Pammel 1911; Watt & Breyer-Brandwijk 1962).

Lolium perenne is a caespitose perennial grass, similar in habit to L. temulentum; culms green to straw-coloured. Leaf blade plicate when young, 3-20 x 0.2-0.6cm. Spikes 4-30cm long, stiff, slender to somewhat stout; spikelets 7-20mm long, 4-14-flowered, elliptic to obovate-elliptic in lateral view; superior glume shorter than the rest of the spikelet, 5-7-nerved, narrowly lanceolate, apex usually obtuse, smooth; lemmas 5-7mm long, 5-nerved, muticous, imbricate, obovate-oblong or oblong, apex acute to subobtuse; paleas with scaberulous keels; anthers 3-4mm long; caryopsis c.4.5mm long (Exell & Wild ed. 1960).

Introduced over much of the temperate world; a weed in all states of Australia (Parsons & Cuthbertson 1992).

The fungus **Acremonium lolii** is identified by the presence of septate, intercellular, infrequently branched hyphae running longitudinally in the leaf-sheaths; conidia ellipsoid to reniform, 5-7µm long, produced simply on slender conidiophores; it is also found in the grain, and is quite variable in its characteristics.

L. perenne is also sometimes host to the seed-transmissible Gliocladium-like and Phialophora-like fungi, most often in cosymbiosis with Acremonium spp.; these have penicillate conidiophores (Christensen et al. 1991, 1993; Siegel et al. 1995). It has also recently been found to sometimes be host to Tilletia walkeri, which can also infect other Lolium spp. T. walkeri has tuberculate teliospores, and the surface of the exospore is made up of incomplete cerebriform ridges (Castlebury & Carris 1999). Freeman & Ward (1902) gave a detailed description of the growth of the Acremonium sp. endophyte of L. temulentum, the fungus still being unidentified at that time.

LONCHOCARPUS

(Leguminosae/Fabaceae)

Lonchocarpus violaceus *Benth.* **(L. benthamianus** *Pittier***; L. longistylus** *Pittier***; L. violaceus** *(Jacq.) Kunth. ex DC.***; L. violaceus** *Oliv.***)** – balché, lancepod, greenheart, savonette, savonette le ba, savonette petite feuille

The 'balché' tree has long been cultivated and held sacred by the Maya of Yucatan [Mexico], n. Guatemala, and British Honduras, who use it to prepare a ritual beverage of the same name. It is consumed communally in times of need, to re-establish links with the gods [who gave the balché ritual to the Mayan ancestors], or sometimes for almost any reason that can be thought of off-hand [as with the Lacandon Maya]. The brew was once taken rectally as an enema, but today is usually only consumed orally. The beverage is prepared in a specially-made canoe, which is sometimes made from the balché tree itself. Water is added to the canoe; wild honey [which usually may not be consumed for more trivial purposes] is then dissolved in the water to a ratio ranging from 1:1 to 2:1 [water:honey]. Old, used pieces of balché bark, probably harbouring yeast colonies, are crushed and added, along with fresh bark strips, and sometimes root, equivalent to 4 strips each c.33cm long per brew [it was not noted how many people this would serve]. This mixture is then fermented for 3-6 days, with a final alcohol content of 1-5%. Incantations are uttered throughout the early stages of preparation, calling in the spirits of toxic plants and creatures of the jungle, some of which may also be added to fortify the brew [see *Methods of Ingestion*].

Before group consumption in a ritual circle, the 'soul' of balché is offered to each of the gods in turn in a palm-leaf cup [or other appropriate vessel], held up to the heavens. A conch-shell is sounded, which invites everyone to attend the circle to drink. All are served an equal amount from a central pot, and all drink simultaneously. Over the next few hours, 17 litres or more may be consumed by each person, with frequent vomiting, urinating and defecating to make room for more. Effects, which manifest quickly, consist of euphoria, feelings of good-will, sharpened perceptions, muscle relaxation, emesis, and purging, followed finally by a deep sleep. There is said to be little subsequent hangover. Apparently, even after drinking large quantities, one does not feel drunk, despite the alcohol content, due to a modification of action from the balché bark. When made with 'kava' [see **Piper 2**] in place of L. violaceus, the effects are very similar (De Lima et al. 1977; Montgomery pers. comm.; Rätsch 1990, 1992; Rätsch pers. comm.).

It should also be noted that in Yucatan, a stingless bee collects honey from **Turbina** corymbosa; this honey is said to be quite inebriating (Ott 1998a). It is not known whether the wild honeys used for preparing balché similarly bear psychoactive constituents from such a source.

In Central and South America, the roots of some Lonchocarpus spp. [such as L. nicou (L. floribundus) and L. densiflorus] are thrown into water as a fish poison. In Brazil L. urucu is used for this purpose, but it is the leaves and stems which are valued, rather than the root. The use of these plants in stupefying fish is due to their rotenone content [up to 20% in L. nicou dry root]. Species high in rotenone have a thick, abundant latex. Rotenone is a neurotoxin which is generally considered non-toxic to mammals (Allen & Allen 1981; Prance 1972; Usher 1974). However, recent animal studies have implicated rotenone [i.v.] in causing some symptoms of Parkinson's disease, with chronic exposure (Butcher 2000; Greenamyre et al. 1999). Canavanine [see **Canavalia**] has been found in some Lonchocarpus spp., such as L. bussei, L. capassa, L. cyanescens, L. eriocalyx, L. laxiflorus and L. neisii (Bell et al. 1978).

L. violaceus root bark has yielded 16% of a raw extract, containing prenyl-stilbenes called longistylines [similar to *kawain* from kava – see **Piper 2**], and rotenone; the root has yielded 1.4% longistyline A, 0.3% longistyline B, 1.3% longistyline C and 0.7% longistyline D. All of the longistylines have antibacterial properties (De Lima et al. 1977; Monache et al. 1977; Rätsch 1992), but their potential psychoactive properties seem to be uninvestigated. Seeds have also yielded the peptide enduracididine and traces of 4-OH-arginine, as well as the alkaloids 2-amino-4,5-dihydro-1H-imidazole-4-acetic acid, and 3,4-dihydroxy-2,5-bis(OH-methyl)pyrrolidine (International… 1994).

Lonchocarpus violaceus is a small, glabrous tree. Leaves alternate, imparipinnate; leaflets in 3-5 pairs, ovate, translucent-dotted, to 8.9cm long, dark green above. Flowers numerous in axillary racemes to c.25cm long; bracts small, caducous; bracteoles 2; calyx truncate, lobes short or obsolete, 2 uppermost ones longer and connate; petals whitish outside, pale purple or pinkish inside, standard orbicular-obovate, with 2 basal ears, wings oblique-oblong, clawed, eared, slightly adherent to the keel above the claw, keel obtuse, eared, clawed; stamens 10, 1 of them separated at the base but united above with the other 9; anthers versatile. Ovary silky-pubescent, 2-many-ovuled; style incurved, filiform; stigma small, terminal. Fruit a flat, indehiscent leguminous pod, lanceolate, membranous or leathery, to 5.9cm long and half as wide, 1-seeded; seeds round, flat or kidney-shaped.

S.e. Mexico, Guatemala, British Honduras, West Indies, Colombia, Venezuela, Zimbabwe; cultivated as an ornamental (Allen & Allen 1981; Bailey & Bailey 1976).

LOPHANTHERA

(Malpighiaceae)

Lophanthera lactescens *Ducke*

This tree has been reported to be used as a source-plant in some S. American ayahuasca brews, in place of **Banisteriopsis** caapi (Schultes 1986). It is also drunk as a therapeutic tea in the Amazon, reputed to have febrifugal properties (Ribeiro & Machado 1947). L. pendula leaves are used as a strong diuretic in the upper Rio Negro region of Brazil (Schultes & Raffauf 1990).

L. lactescens leaves have yielded lophanterine, an alkaloid of unknown structure [has an extremely bitter taste, and febrifugal properties] (Ribeiro & Machado 1947); (4R,6α,7α,15β,16β,18β,21β,22α)-6,7,15,16,24-pentaacetoxy-22-carbomethoxy-21,22-epoxy-18-OH-27,30-bisnor-3,4-seco-1,20(29)-friedeladien-3,4-olide has also been found in the plant (Buckingham et al. ed. 1994).

Lophanthera lactescens is a tree up to 15m high, young parts with bitter white latex; adult branches glabrous. Leaves opposite, generally 20-30 x 8-14cm, above applanate-canaliculate, sparingly pilose, at length glabrous, obovate, base cuneate-attenuate, apex obtuse or subrotundate, plane, membranaceous, on both sides glabrous and shiny; petiole 2-2.5cm long, moderately robust; stipules connate in petioles, 1-1.5cm long, base robust, triangular, apex subulate, rarely shortly bi-fid, appressed pilose, margin villose, soon glabrate. Inflorescence a raceme, usually to 50cm long, reddish-pubescent, lateral branching alternate, dense, numerous, commonly biflowered; flowers c.1.25cm diam.; bracts and bracteoles ovate-lanceolate, to 1.5mm long, bracteoles moderately large, terminating in a long stipe; calyx 5-partite, 10-glandulose; sepals ovate-lanceolate, acute; petals golden-yellow, oblong-obovate, clawed, margin revolute, c.6mm long; stamens 10, all fertile; filaments bearing hairs, united with stamen at base; anthers 1.5-2mm long, glabrous. Ovary triloculer; locules oblong, lateral exterior appendiculate, cristiform, verrucose, decurrent near base; styles 3, ventrifixed, subulate, acute. Fruit a capsule c.5mm long, tricoccous, carpophore lacking, slowly loculicidal; seeds subglobose, testa crustaceous.

Habitat near rivers, not on flooded land, in old-growth secondary forest; near middle Tapajos river, Pará river, Brazil (Ducke 1925; Engler & Niedenzu 1928; Fridericus & De Martius ed. 1965-1975).

LOPHOPHORA

(Cactaceae)

Lophophora diffusa *(Croizat) H. Bravo* **(L. echinata** *Croizat* **var. diffusa** *Croizat***; Anhalonium williamsii** *Rümpler***; A. williamsii** *(Lemaire) Lemaire***)**

Lophophora fricii *Haberm.* – possibly hikuri walula saeliame, or jíkuli huálala saeliami ['hikuri of great authority']

Lophophora jourdaniana *Haberm.* **(Anhalonium jourdanianum** *Lewin***; Echinocactus jourdanianus** *Rebut ex Maas***)**

Lophophora williamsii *(Lemaire) J. Coulter* **(Anhalonium lewinii** *Hennings***; Ariocarpus williamsii** *Voss***; Echinocactus williamsii** *Lem. ex Salm-Dyck***; Mammillaria williamsii** *J. Coulter***)** – peyote, peyotl, pellote, hikuli, hikuri, jículi, jículi huanamé, huanamé, wanamé, xicori, pejoriseni, azee, ho, makan, beyo, walena, joutouri, kamba, nezats, hunka, challote, mescal buttons, muscale buttons, devil's root, diabolic root, dry whiskey, Indian dope, white mule, good medicine

Lophophora williamsii var. caespitosa *Ito* **(L. caespitosa** *Fric ex Roeder***)** – kobuki-ubadama

'Peyote', L. williamsii, has been used as a ritual entheogen for at least 3,000yrs. The Aztecs used it as a remedy for many ailments in low doses, such as rheumatism, headaches and fever; in higher doses it was used by shamanic priests as a magical plant for divination, and was considered one of the most important entheogens. It was also consumed in water, possibly with pulqué brewed from Agave spp. [see *Methods of Ingestion*], at ritual celebrations. It was eaten by Tarahumara runners to give endurance and speed, and warriors sometimes wore the dried plant as an amulet to give 'superhuman strength' and protection. As well as L. williamsii ['hikuri', 'hikuri huanamé'], the Tarahumara used a great variety of medicinal and magical cacti [eg. see also **Mammillaria**]. M.S. Smith (2000) has suggested the 'hikuri walula saeliame' ['hikuri of great authority'] known to the Tarahumara might have been L. fricii.

With the coming of the Spanish conquest, peyote was one of the first 'demonic' plants noticed by the invaders, and its users were persecuted and driven into hiding. Today, it is still widely used by the Huichol, to whom it is the most important entheogenic link with the great spirit 'Hikuri', which is also their name for the cactus, and for the deer, all of which are synonymous in the Huichol cosmology. Once a year, they make a pilgrimage [of which there are lengthy descriptions in some of the references below] to their sacred collecting ground, 'Wirikuta', the mythic place of origin, where Hikuri and the 'Kakauyarixi' [the divine ancestors of the Huichol] dwell. The trek is led by a shaman who is in touch with Hikuri, and is preceded by a ritual of confession of the sexual histories of all present. No one is permitted to show anger or jealousy; a knot is tied in a cord for each confession, before it is burnt in the fire in a rite of purification. The members of the procession take with them only tobacco [see **Nicotiana**], water and tortillas for provisions. Once the 'hunt' for peyote begins at Wirikuta, the first plant sighted is surrounded with arrows fired to mark the 4 cardinal points around the plant; all present cry, pray and make offerings of tobacco-gourds, while the shaman pushes the 'spirit of the dying deer' back into the plant with his prayer-arrow. The plant is then respectfully sliced off at ground level with a sharp knife, and small pieces of the 'button' are distributed for all to chew. Later, the hunt begins in earnest, with buttons being harvested with true love, and apologies made for removing them from their home. The day concludes with an all-night peyote session, and the next day the group leaves for home, with the year's peyote supply [both for their own people, and for trade with other peyote-using groups who have no pilgrimage] (Anderson 1996; Bravo 1937; Bye 1979b; Diaz 1979; Furst 1976; Kloesel 1958; Rätsch 1992; Schaefer 1995; Schultes 1937a, 1937b; Schultes & Hofmann 1980, 1992; Wasson 1963).

By the beginning of the 1870's, peyote use had begun to spread north as journeys into Mexico by native American peoples brought back news of its lofty virtues. In the US, indigenous people had begun to be confined in reservations, and many were losing their cultural identity and heritage, and most importantly, their spirituality. The Kiowa and Comanche were the first to start the spread of peyote, adapting its use to the needs of modern 'Indians', as an effort to return cultural pride and a connection with the great spirit; many other men had an important part in the spread of this movement. In 1918, the Native American Church was officially formed to protect the right of native people to use peyote, which was by then illegal in the US. They held out against massive pressure from local government and church groups, and continue to be a major church today; peyote use is still illegal in the US for non-native users, and even the legal use by church members still faces regular uncertainties in circumstances where local law enforcement officers are less than sympathetic. Church members usually live by a code of ethics known as the 'peyote road', including the practice of honesty, love, sharing, care of the family, self-reliance, and abstinence from alcohol – this last point is sometimes loosely adhered to, but it is generally held that alcohol should never be drunk with peyote. It has been said that "a peyote lesson can be as gentle as a baby, or as harsh as your lack of respect." Peyote also enjoys medicinal uses, besides being 'medicine for the spirit' – it acts as an effective tonic stimulant, topical analgesic, antirheumatic, antipyretic, haemostatic, antibiotic and antiseptic; the juice can also be applied to wounds, forming a flexible scab which holds the wound together, speeding the healing process (Anderson 1996; Bye 1979b; Farnsworth 1968; McCleary et al. 1960; Mount 1993; Ott 1993; Schultes 1937a, 1937b, 1969c; Stafford 1992).

Many readers will expect a description of an 'authentic' peyote ceremony; however, each group has their own variations. For greater detail on different practices, see the references listed. Below is a broad summarisation of some of the elements involved in Plains Indians practices.

The ceremony is presided over by the 'Roadman', who is aided by the 'Chief drummer' [keeps up the drumbeat all night on a water-drum], 'Fire chief' [attends the fire, tends the sick, watches the door], and 'Cedar man' [uses cedar incense to revive the disoriented; see **Juniperus**]. They erect the meeting place for the ceremony, which is often a tipi with a fireplace in the middle; a crescent-moon shaped altar is set up, on which is later placed a large peyote specimen ['father peyote'] on a bed of **Artemisia** ['sagebrush']. Ritual paraphernalia [such as a gourd-rattle, incense, eagle feathers etc.] is arranged in preparation. The ceremony begins just after dark. When the father peyote is placed on the altar, informalities cease and the ceremony has begun. Tobacco cigarettes are rolled in corn-husks and passed around; tobacco is smoked throughout the night. Prayers are offered, incense is burnt, participants 'smudge' themselves with smouldering bunches of **Artemisia** ['smudge sticks'] and the bag of peyote is passed around for all to consume several buttons. More peyote may be eaten at any time through the night as needed. Those who become ill leave the tipi to vomit and are 'smudged' by the Cedar man before re-entering. At midnight, the Roadman leaves the tipi and blows his eagle-bone whistle to the four corners of the earth. The ceremony continues until dawn, when a 'peyote woman' enters the tipi and distributes water and basic food. At the conclusion, the participants join the tribe for a communal meal, after the ritual paraphernalia has been packed away and the area cleaned (Anderson 1996; Schultes 1937a; Schultes & Hofmann 1992).

Today, the non-traditional gathering of peyote in the wild has severely diminished its natural distribution, and diverted supplies from traditional groups who require it for their spiritual practices. Peyote is now endangered in the wild [due to over-collection, ploughing up of habitat, and landowners barring access to their properties for legitimate collection], and should only be collected from specimens cultivated from seed or cuttings (Anderson 1995). Traditional harvest time [for best psychological effect, and least somatic side-effects] is December to April or mid-May; some experienced users say January and February are the best times. At other times of the year, the tetrahydroisoquinolines [THIQs] are found in greater proportion to *mescaline* and related phenethylamines. The plant is harvested by slicing level with the ground, or preferably just above ground level, leaving some green growth; this latter method ensures the best chance of regeneration. This above-ground portion is known as the peyote button, and is often dried – a dried button c.2-3cm diam. constitutes one 'button-unit' for dose calculation when no scales are available. The root is preferably dusted with charcoal or sulphur dust and allowed to form a dry callus, and left in the ground to regenerate. Many new heads will sprout from the root in time, if it survives. Peyote buttons may be taken fresh or dried, and may be chewed, or decocted and drunk. The white

tufts of hair are usually plucked out before chewing. Some traditional groups press the fresh plants on a metate, collecting the juice and mixing it with water for consumption. The cactus is extremely bitter in taste, and nausea and vomiting often develop early in the experience [many native users believe the degree of vomiting is associated with impurities of body and spirit]. Some say it is best to consume it slowly over a period of time, to lessen the shock to the system [a method of questionable validity, according to some – see **Trichocereus**]. A good technique of chewing is to chew the button up with the front teeth, tossing the smaller pieces to the back of the mouth to be swallowed. Effects begin to be felt in 1-3hrs, and are similar to those of *mescaline* alone; however, the experience is qualitatively different due to the many other active compounds present. Duration is up to 12hrs or more (Mount 1993; Schultes & Hofmann 1980, 1992; Stafford 1992; Trout & Friends 1999; pers. comms.).

The effects of L. diffusa, which is low in *mescaline* but fairly rich in THIQs, differ greatly, bearing more similarity to anticholinergic hallucinogens, in some reports. Effects may include "clumsiness, confusion, general malaise and prolonged diaphoresis…two individuals described pleasant effects characterised by tranquillity and mental clarity accompanied by visual and especially auditory images" (Diaz 1979). Another individual ingested 20 buttons of L. diffusa, which had been decocted in aguardienté liquor, and reported a **Datura**-like experience (http://www.lycaeum.org/drugs/trip.report/view_report.cgi?RowID=246).

Phenethylamine will, in most cases, here be abbreviated to PEA.

L. diffusa has yielded 0.9% alkaloids [w/w, whole plant], mostly *pellotine* [1.997-2.213%; over 90% of total alkaloids], with traces of *mescaline* [0.006-0.03%; c.1% of total alkaloids], as well as [given as % of total alkaloids] the isoquinolines isopellotine, O-methylpellotine, 5% anhalamine [6,7-dimethoxy-8-OH-THIQ; claimed to have physiological activity similar to *mescaline*], 3.8% *anhalonidine* [6,7-dimethoxy-8-OH-1-methyl-THIQ], 0.6% anhalinine [6,7,8-trimethoxy-THIQ; similar effects to anhalamine], 0.7% O-methylanhalinine, 0.1% anhalidine, 0.1% anhalonine [6-MeO-1-methyl-7,8-methylenedioxy-THIQ; excitant in animals], 0.1% lophophorine [1,2-dimethyl-6-MeO-7,8-methylenedioxy-THIQ; excitant in animals; in humans, 20mg has caused headache, vasodilation, hot flushing, nausea, and slowed pulse, effects lasting c.40 min.]; and *phenethylamines* – 0.1% *tyramine*, 0.1% N-methyltyramine, 0.5% *hordenine* and 0.1% N-methylmescaline (Bruhn & Holmstedt 1974; Kloesel 1958; Shulgin & Shulgin 1997; Starha 1997; Trout & Friends 1999).

A sample identified as L. diffusa var. koehresii yielded [as % of total alkaloids] 86.27-90.51% *pellotine*, 4.42-5.06% anhalamine, 2.63-4.27% *anhalonidine*, 0.97-1.67% *mescaline*, and lesser amounts of *hordenine*, anhalinine, anhalonine, anhalidine, O-methylanhalidine, O-methyl-*pellotine*, lophophorine, N-methylmescaline, 3,5-dimethoxy-4-OH-*PEA*, N-methyl-*DMPEA*, *tyramine* and N-methyltyramine (Štarha & Kuchyna 1996). A specimen identified as L. echinata yielded [w/w] 0.003% *mescaline* (Siniscalco 1983).

L. fricii yielded 1.607-2.031% *pellotine*, c.0.014% *mescaline*, and [as % of total alkaloids] 24.9-25.9% *anhalonidine*, 2.2-2.7% anhalinine, 1.9-2.3% O-methylanhalinine, 1% anhalidine, and lesser amounts of *tyramine*, N-methyltyramine, *hordenine*, N-methylmescaline, anhalamine, anhalonine and lophophorine.

L. jourdaniana yielded 0.585-0.795% *mescaline* [31% of total alkaloids in one test], 0.621-0.799% *pellotine* [17.8% of total alkaloids in one test], and [as % of total alkaloids] 20.1% *anhalonidine*, 3.2% N-methylmescaline, 2.9% *hordenine*, 3.1% anhalidine, 1.7% anhalamine, 1.1% anhalonine, 1.4% lophophorine, and lesser amounts of *tyramine*, N-methyltyramine, anhalinine and O-methylanhalinine (Štarha 1997).

L. williamsii has yielded 0.4[w/w, whole plant]/0.93[w/w]-8.86% alkaloids; roots have yielded 0.2% alkaloids [w/w] (Bruhn & Holmstedt 1974). *Mescaline* is the major component in mature plants, and content averages at 1% [though up to 6% has been found], or 15-30% of the total alkaloids; as well as [as % of total alkaloids] 0.74-17% *pellotine*, isopellotine, O-methylpellotine, 0.5-5% lophophorine, peyophorine [2-ethyl-6-MeO-1-methyl-7,8-methylenedioxy-THIQ], 0.1-8% anhalamine, 1,2-deyhdroanhalamine, N-formylanhalamine, N-acetylanhalamine, isoanhalamine, 0.001-10% anhalidine, isoanhalidine, 0.01-0.5% anhalinine, 0.5% O-methylanhalinine, N-formylanhalinine, 0.5-3% anhalonine, N-formylanhalonine, N-acetylanhalonine, 5-14% *anhalonidine*, isoanhalonidine, O-methylanhalonidine, N-formylanhalonidine, N-formyl-O-methylanhalonidine, 1,2-dehydroanhalonidine, 1,2-dehydroanhalidinium quaternary salt, 1,2-dehydropellotinium quaternary salt, peyotine iodide quaternary salt, anhalotine iodide, peyoxylic acid, O-methylpeyoxylic acid, peyoruvic acid, peyoglutam, mescalotam, peyotine iodide, and lophotine iodide; the other major group of alkaloids present are the *phenethylamine*s, of which *mescaline* is a part – as well as 0.5-1% *tyramine*, 0.5-1% N-methyltyramine, 5-8% *hordenine* [anhaline, peyocactin – an antibiotic; mostly in roots], *dopamine*, epinine, 3-MeO-*tyramine* [homovanilylamine], 3-MeO-N-methyltyramine, N,N-dimethyl-3-MeO-*tyramine*, 3,4-dimethoxy-phenethylamine [*DMPEA*], 3,4-dihydroxy-5-MeO-*PEA*, 5% 3-OH-4,5-dimethoxy-*PEA* [3-demethylmescaline; unstable, absent in old material], 4,5-dimethoxy-N-formyl-3-OH-*PEA*, N-acetyl-4,5-dimethoxy-3-OH-*PEA*, 4,5-dimethoxy-3-OH-N-methyl-*PEA*, 3-demethyl-trichocereine, 3% N-methylmescaline, N-formylmescaline, N-acetylmescaline, *mescaline* succinamide, *mescaline* malimide, *mescaline* maleimide, *mescaline* citrimide and *mescaline* isocitrimide lactone; peyoglunal, peyonine, N-(3,4,5-trimethoxyphenethyl)*glycine*, N-(3,4,5-trimethoxyphenethyl)alanine and *choline* have also been found (Anderson 1996; Bruhn & Holmstedt 1974; Crosby & McLaughlin 1973; Gennaro et al. 1996; Kapadia & Fayez 1970; Kapadia et al. 1968; Kloesel 1958; Lundstrom 1989; McCleary et al. 1960; McLaughlin & Paul 1966; Shulgin 1973; Shulgin & Shulgin 1997; Siniscalco 1983; Štarha 1997; Todd 1969). 'Buttons' may lose 89% water on drying (Bruhn & Holmstedt 1974). Younger plants yield lower levels of alkaloids (Gennaro et al. 1996), as do cultivated plants receiving plenty of water (pers. comm.). Recently, methanol extracts of L. williamsii have been found to have some anti-tumour and immune stimulant activities (Franco-Molina et al. 2003).

L. williamsii var. caespitosa has yielded 0.616-0.786% *mescaline*, 0.205-0.396% *pellotine*, 0.029% *anhalonidine*, 0.146% anhalidine, anhalamine and lophophorine, as well as betaine derivatives – 0.036% anhalotine [3,4-dihydro-8-OH-6,7-dimethoxy-2-methylisoquinolinium inner salt], peyotine [3,4-dihydro-8-OH-6,7-dimethoxy-1,2-dimethylisoquinolinium inner salt], 0.022% 3,4-dihydro-8-OH-6,7-dimethoxyisoquinolinium inner salt, and 0.0036% 3,4-dihydro-8-OH-6,7-dimethoxy-1-methylisoquinolinium inner salt (Fujita et al. 1972; Štarha 1997).

Lophophora williamsii is a cactus, stems solitary to numerous, glaucous-green to bluish-green, depressed-globose to depressed-cylindroid, mound-like, mature plants to 2.5-7.5cm high or more (I have seen a specimen clumping to 25cm high), 5-10cm diam.; ribs mostly c.8-12; younger tubercles at apex bulging, to 5mm high, the older ones flattening out as stem enlarges, irregularly-hexagonal, to 25mm diam.; areoles 2-4mm diam., typically 12-25mm apart, during the first year of growth in mature plants bearing a dense tuft of white, +- silky hairs to 7-10mm long, later in a compact cylindroid tuft with ends broken off; spines none (seedlings with a few weak, bristle-like spines). Flower apical, 12-25mm diam., 12-30mm long; sepaloids with greenish middles and pink margins, the largest narrowly oblanceolate, 9-15mm long, to 3mm wide, strongly cuspidate, acute, margin entire; petaloids pink in middles, pale to nearly white at margins, the largest oblanceolate, 12-15 x c.4mm, acute and cuspidate, entire; filaments pale, c.2mm long; anthers yellow, 1-1.4mm long; style white, tinged with pinkish, to 9 x 1-1.5mm; stigmas 5, 2 x c.1mm, thin and flattened; ovary in anthesis turbinate, 3-4.5mm long, smooth, not scaly, surrounded by hairs to 12mm long. Fruit red, walls thin and transparent, fleshy at maturity, elongate, clavate or nearly cylindroid, enlarged gradually upwards, 12-20 x c.3-5mm; seeds densely papillate, 1.25mm long, c.1mm wide, 0.8mm thick.

In limestone or partly limestone soil in hills, alluvial fans, and desert flats, 150-1200m; Chihuahuan Desert, Rio Grande Plain, Texas, n. Mexico (Benson 1982; pers. obs.).

L. williamsii var. caespitosa refers to specimens with several stems arising from the one root; however, this is not an unusual feature and the plant is otherwise the same as L. williamsii (Anderson 1996), though often sold as L. caespitosa in the horticultural trade (pers. obs.).

Most botanists accept two species of Lophophora – L. diffusa and L. williamsii [some believe the genus consists of only the latter], L. diffusa differing mainly from L. williamsii with its yellowish-green skin, indistinct or absent ribs, and whitish to yellowish-white flowers. It also has a smaller, more southern distribution [state of Querétaro, Mexico], and is distinguished by its alkaloid profile [see above]. L. fricii and L. jourdaniana are two putative classifications which some argue belong with L. williamsii. L. fricii differs from typical L. williamsii with its many distinguished ribs, grey-green skin, 'carmine-red' flowers, and seeds with a coarse coat and compressed V-shaped hilum. The type specimen was collected near San Pedro, Coahuila [Mexico]. The material studied under this name has an alkaloid profile more similar to that of L. diffusa, than to that of L. williamsii. L. jourdaniana is said to differ from L. williamsii with small, persistent spines on young areoles, and having a rose-violet perianth, pistil and filaments (Anderson 1996).

Lophophora spp. are very slow-growing – L. williamsii may take 50 years to reach maturity. It can be cultivated from cuttings or seed. Seeds are collected with tweezers from the old flowers, and should be kept dry and in the dark until planted. Germinate as for other cacti; seeds may germinate in 3-7 days. Cuttings of buttons root best in spring, and once the cut has dried over, are simply planted on the ground on which they are to grow. They will grow much faster if grafted to a small **Trichocereus** spp. stock of a similar diameter. A soil mixture should preferably use crushed limestone, coarse sand, and desert topsoil blended with rotted leaves and rabbit manure. Cuttings will grow in commercial cactus potting mix, but to this should be added gypsum or dolomite lime, and organic fertiliser once roots have formed and new growth is obvious. Soil analyses of peyote's natural habitat indicate "limestone in origin, with pH 7.9-8.3. More than 150ppm calcium, at least 6ppm magnesium, no more than 3ppm phosphorous, strong carbonates and no more than trace amounts of NH3." Water plants as often as the soil dries out, but keep on the dry side; too much is worse than none at all. Withhold water in late autumn and winter, when cacti are in dormancy. Cool, damp conditions will rot

the plant; it can tolerate temperatures as low as 5°C [sometimes even less, if not for extended periods and if the plants are healthy and robust]. Gradually expose seedlings to sunlight; in temperate climates, peyote may be able to deal with full sunlight for part of the day; in hotter, sunnier climates, plants require more dappled shade (Mount 1993; pers. obs.).

LUPINUS

(Leguminosae/Fabaceae)

Lupinus angustifolius *L.* – narrow-leaved lupin, blue lupin, lupino azul
Lupinus hirsutus *L.* **(L. pilosus** *L.***)** – agriolupino
Lupinus nootkatensis *Donn ex Sims* **(L. perennis ssp. nootkatensis** *(Donn ex Sims) L. Phillips***)**
Lupinus spp. – lupins, lupines

In ancient Greece, lupins were considered a magical and healing food. L. hirsutus is thought to be the Thermos referred to by Dioscorides, which was used in folk medicine as an antidiabetic and emmolient. Pilgrims to the death oracle of Acheron in ancient Greece consumed large amounts of L. angustifolius or L. hirsutus seeds, in order to come into contact with spirits of the dead; due to their toxic nature, it would seem likely that some of them stayed with the dead (Rätsch 1992; Souleles 1990)! However, there are relatively non-toxic varieties of L. angustifolius known as 'sweet lupin', which have non-bitter, edible seeds, and low alkaloid content throughout the plant. Presumably, such non-toxic varieties would have been those consumed by the Greeks. For years grown as food for stock animals, the seeds are now becoming more accepted as a protein-rich food for humans (Brooke et al. 1996). This may change now that non-alkaloidal toxins have been found in the seeds (Rahman 2000).

In N. America, the Tlingit and Kwakiutl ingested L. nootkatensis roots to produce an intoxication. Animals grazing on the plants often develop intoxication, sometimes leading to death or illness; pregnant animals can give birth to deformed young. Two different forms of stock poisoning have been noted – 'European lupinosis', with symptoms including depression, loss of appetite, jaundice and liver damage; and 'American lupin poisoning', causing staggering, convulsions, respiratory depression, dyspnoea and frothing at the mouth. The latter syndrome has been attributed to the alkaloids present in the plants; the former syndrome generally appears after prolonged feeding on lupin fodder (Gardner & Bennetts 1956; Keeler 1975; Lipp 1995; Pammel 1911).

Roasting the seeds of some species can remove toxins, and they may then be ground and used as a coffee substitute [see **Coffea**] (Bremness 1994; Chiej 1984). In parts of South America, a preparation known as 'wilka tarwi' or 'bilca tauri' was once taken both orally and rectally as a purgative which gave health and strength for battle. 'Wilka' is a derivation of 'villca', a term often applied to some **Anadenanthera** spp. 'Tauri' is the name for the seeds of L. mutabilis, which are not known to be psychoactive. It is not known whether Lupinus spp. seeds were used in this preparation (Torres 2001; Trout ed. 1998).

The genus name comes from the Latin 'lupus', or 'wolf', apparently referring to the notion that lupins take over the land and ruin its productivity – a strange belief, as lupins, like many other legumes, fix nitrogen and phosphorous in the soil and make a good green manure, as well as absorbing excess toxins from the soil. For this latter reason, lupins were planted around Chernobyl after the infamous disaster there (Allen & Allen 1981; Bremness 1994). Today, lupins are commonly grown as ornamental garden plants. Although not all species contain toxic principles, most do; the most toxic parts are generally the seeds and pods, as well as young leaves and stems in spring. Ingestion can induce nervousness and excitability, followed by depression; symptoms of severe poisoning may include nausea, abdominal pain, vomiting, dizziness, salivation, headache, and slowed heartbeat and respiration; death can occur, but is rare. As mentioned above, Lupinus spp. are also sometimes responsible for poisoning stock animals (Foster & Caras 1994; Keeler 1975; Turner & Szczawinski 1991), and some N. American species rich in anagyrine [such as L. sericeus] are teratogenic to cattle (Bruneton 1995; Keeler 1975).

The safest mode of use is probably to smoke the dried herbage [collected at flowering], or dried, ground seed pods (pers. obs.). One adventurous person consumed c.150ml of a 'lupin seed' decoction as an enema, on two separate occasions, and experienced "malaise, unpleasant sensations in the head, dimness of vision, palpebral heaviness, dizziness, mental excitation, and laryngeal and pharyngeal constriction" (Felter & Lloyd 1898).

Lupinus spp. predominantly contain quinolizidine alkaloids, some of which affect *acetylcholine* receptors. Of these, some [such as lupanine] are active mainly at nicotinic *acetylcholine* receptors, and others [such as angustifoline, multiflorine, sparteine (CNS depressant), 3β-OH-lupanine and 13α-tigloyloxylupanine] act mainly at muscarinic *acetylcholine* receptors (Nucifora & Malone 1971; Schmeller et al. 1994).

L. angustifolius alkaloids accumulate in the leaves and stems, until flowering and fruiting, with highest alkaloid concentrations ending up in the ripe seeds. Seeds [from bitter varieties] have yielded up to 2% alkaloids, including lupanine [c.44% of alkaloids; lupanine is known to be a CNS depressant, hypotensive, antiarrhythmic and hypoglycaemic], 13-OH-lupanine [c.38% of alkaloids], α-isolupanine [c.1% of alkaloids], and angustifoline [c.16% of alkaloids]; sparteine, isoangustifoline, dehydroangustifoline, multiflorine [CNS depressant] and tetrahydrorhombifoline are also found in the seeds. Seeds of sweet varieties have yielded 0.04-0.21% alkaloids; they are characterised by containing much less lupanine, 13-OH-lupanine, and angustifoline, though sparteine, isolupanine, and isoangustifoline levels are not significantly different to those in seeds of bitter varieties. *Gramine*, wighteone, orobol, lupinic acid, angustones A-C, N-γ-glutamyltyrosine, and flavonoids such as genistein [MAOI (Hatano et al. 1991)] have also been found in the plant (Brooke et al. 1996; Buckingham et al. ed. 1994; Christiansen et al. 1997; Harborne & Baxter ed. 1993; Harborne et al. ed. 1971; Henry 1939; International… 1994; Nucifora & Malone 1971; White 1943c). The seeds also contain toxic polypeptides, which interfere with protein synthesis in the liver (Rahman 2000). When plants were water-deprived during vegetative growth, alkaloid yields increased in two sweet varieties [0.094% and 0.192%] and one bitter variety [2.55%]; similar drought stress during flowering and fruiting produced mixed results (Christiansen et al. 1997).

L. hartwegii, L. hispanicus, and L. luteus have been found to contain *gramine* (Leete 1975); seeds of L. luteus tested positive for HCN (Watt & Breyer-Brandwijk 1962).

Other toxic species contain a similar array of alkaloids, and may have broadly similar effects.

Lupinus angustifolius is an erect annual herb to 1.5m tall, much-branched; stems pubescent with appressed or spreading hairs. Leaves alternate, palmately compound, 5-9-foliolate, petiolate; leaflets linear to linear-spathulate, 1.2-3.5cm x 2-5mm, apex obtuse, upper surface glabrous, lower surface sparsely silky to villous; stipules fused to petiole, subulate; stipels absent. Inflorescence of terminal pedunculate racemes 5-20cm long, flowers pedicellate, unscented; pedicel 2-4mm long; peduncle 1-3cm long; bracts caducous; bracteoles usually fused to calyx base; calyx 7-8mm long, deeply 2-lipped, upper lip 2-toothed to entire, lower lip entire or shallowly 2-3-lobed; corolla 11-15mm, blue, often tinged with purple, standard +- circular, ovate or oblong, equal to wings and keel, wings connate at apex, enveloping keel, keel incurved, apex dark and beaked; stamens monadelphous; anthers alternately long and basifixed, and short and dorsifixed. Ovary sessile; ovules 2 or more; style glabrous, incurved. Pod 35-55mm long, shortly hairy, oblong, 2-valved, dehiscent, +- flat, +- constricted between seeds, beak +- filiform; seeds 4-6, ovoid, 5-7mm long, smooth, brownish with white or brown markings, hilum sunken, aril not present. Fl. spring.

Native to Mediterranean and s. Europe; cultivated, widely naturalised [eg. in Australia – e. and s.w. New South Wales, Queensland, Western Australia, Tasmania] (Harden ed. 1990-1993).

LYCOPERDON and SCLERODERMA

(Lycoperdaceae)

Lycoperdon gigantea *Batsch ex Pers.* **(Calvatia gigantea** *(Batsch ex Pers.) Lloyd***; Langermannia gigantea** *(Batsch ex Pers.) Rostk.***; Lasiophaera gigantea** *(Batsch ex Pers.) Smarda***)** – giant puffball, ma bo
Lycoperdon hiemale *Vitt.* **(L. depressum** *Bon.***; Vascellum pratense** *(Pers.) Kriesel***; V. depressum** *(Bon.) Smarda***)** – bolita de tierra, euesco de lobo, afgeplatte stuifzwam, wiesenstäubling, angsröksvamp
Lycoperdon marginatum *Vitt.* **(L. candidum** *Pers.***; L. cruciatum** *Rostkovius***)** – gi'i sawa, hongo de primera classe, bolita de conejo, ternerita dellano
Lycoperdon mixtecorum *Heim* **(L. qudenii** *Bottom.***; Vascellum qudenii** *(Bottomley) Ponce de León***)** – gi'i wa
Lycoperdon pedicellatum *Peck non Batsch* **(L. caudatum** *Schröt.***)** – hakamaatuhkelo, kärröksvamp
Lycoperdon pyriforme *Schaeff. ex Pers.* **(L. cupricolor** *Lloyd***; L. globosepiriforme** *Lloyd***; L. serotinum** *Bon.***)** – stump puffball
Lycoperdon spp. – puffballs
Scleroderma bulla *Heim* **(S. hydrometrica** *(Pers.) Heim* **var. maculata** *(Patouill.) Heim***)** – putka
Scleroderma citrinum *Pers.* **(S. aurantium** *Vaill. ex Pers.***; S. vulgare** *Hornemann***)** – common earthball, poison puffball, pigskin
Scleroderma verrucosum *Bull. ex Pers.* **(Lycoperdon verrucosum** *Bull.***)** – scaly earthball, warted devil's snuffbox
Scleroderma spp. – puffballs, purple-fleshed puffballs, earthballs

Mixtec shamans of Mexico have been reported to use L. marginatum and L. mixtecorum as shamanic drugs. The latter ['first class mushroom'] is preferred over the former ['second class mushroom'], which smells like faeces. A pair of the puffballs are consumed to enter a dream-like state, in which echoes and voices speak to the shaman regarding what s/he needs to know. Other Lycoperdon spp. may also be used by the Mixtec. An unidentified Lycoperdon sp. ['kalamoto', 'pata de perro' ('dog's paw')] is

used by malicious sorcerers amongst the Tarahumara, in order to make people sick or to approach someone without being seen. Lycoperdon spp. are also important to shamans in Mendocino County, California. Puffball spores have been known to act as a 'chloroform-like' anaesthetic and narcotic when inhaled, though inhalation of the spores can cause serious lung inflammation ['lycoperdonosis'] (Diaz 1979; Emboden 1979a; Heim 1963b; Ott 1993; Schaecter 1997; Schultes & Hofmann 1980). Some native Americans use puffball spores to apply to wounds, due to their astringent properties (Hamel & Chiltoskey 1975). Plains Indians have been reported to have strung puffballs like beads on 'shamanic necklaces' (Morgan 1995), though in at least some cases, this has been a confusion with carved sporophores of Haploporus odorus and/or Fomitopsis officinalis [see *Endnotes*] (Blanchette 1997; Blanchette et al. 1992). In Chile, the Mapuche possibly use an unidentified Lycoperdon sp. ['pëtremquilquil', meaning 'tobacco of Chuncho' (a human-headed shamanic bird) or 'powder of the devil'] for shamanic transformation and flight. In Colombia, Kogi shamans reportedly use a "bluish puffball" and other fungi for their psychoactivity (Rätsch 1998).

The Germans have a wide variety of colloquial names for Lycoperdon spp., all with the prefix 'hexen' ['hexenbeutel', 'hexenei', 'hexenfurz', 'hexenmehl', 'hexenpilz', 'hexenpüsters', 'hexenschiss', 'hexenschwam', 'hexenstaub'], pointing to possible use by witches in the past (De Vries 1991). L. pyriforme may have been used by Basque witches. In one person, the species provoked a 'short-acting narcosis', taking effect 30-60min after consumption of about 7 specimens (Morgan 1995). There is one report of a person who consumed roughly 20-30 young specimens of English origin, sliced and fried in olive oil, followed by a spicy meal. Gastric disturbances were experienced after 2 hours, followed later by mild stimulation. Sleep followed with very intense dreaming, which frequently interrupted sleep. During waking periods auditory and colour perception were enhanced. A hangover was experienced for several days after the meal (theobromus pers. comm.). 'Narcotic' effects have also been reported from meals of Lycoperdon spp. in the US (Ott 1993), such as L. hiemale and L. pedicellatum (Rätsch 1998).

L. gigantea [now usually known as Calvatia gigantea] is used in TCM to treat tonsillitis and sore throat, and the spores are used as a topical haemostatic. The dried fungi are used in a dose of 1.5-6g, wrapped in cheesecloth and boiled in water for 20-30 minutes. The spores have shown some antibacterial activity, and both fruiting bodies and spores have shown some antitumour activity (Hobbs 1995). In England, puffballs such as this species have also been used as haemostatics and tinder. A tincture [25% strength] has been used as a sedative to treat 'nervous affections' (Grieve 1931).

Scleroderma bulla is known by the Santals of Orissa, India, as 'putka', and they collect it when it breaks through the ground, to be eaten as food. If it is not eaten shortly after harvesting, it develops a 'cadaver-like' odour. Though the Santals do not have any known sacred uses for this fungus, their name for it signifies that it is 'animate', or has a soul, and they do not attribute this property to any other members of the plant kingdom. Putka is thought to be synonymous with 'putika', a substitute for soma that is no longer used. As a soma-substitute, putika was not consumed, however. It was used as an admixture to the clay used to make the mahavira vessels, which were placed in the fire for the Pravargya sacrifice, a symbolic ritual of meaning too complex to enter into here. This sacrifice was a late addition to the Vedic Soma sacrifice. Putika may have even been the mysterious last meal of the Buddha [see also **Amanita**]. L. pusillum was reported by one Santal person to be an example of 'rote-putka' [rote = toad or frog], though this may simply be a term applied to all similar puffballs. The Santal recognise two other forms of putka, 'hor putka' ['man putka'] and 'seta putka' ['dog putka'], which are thought to be different growth-stages of the same species [S. bulla] (Wasson 1968; Wasson et al. 1986).

Scleroderma spp., purple-fleshed puffballs, have occasionally been used as truffle-substitutes or adulterants. Although sometimes considered edible [particularly when sliced and well-cooked], they have been known to cause severe gastric upset and, occasionally, psychotropic symptoms. S. citrinum from Europe has been reported to result in "a feeling of uneasiness, vomiting, perspiration, and unconsciousness" when eaten, though in small amounts, it has been used for its "pleasant aromatic taste" as a truffle-substitute (Stevenson & Benjamin 1961). S. citrinum is also considered psychoactive. Half of one small specimen, eaten, has caused a deep sleep lasting 2hrs [c.15min. after consumption], followed by a restless period, with strongly dilated pupils and visual disturbances, in one psychonaut (Morgan 1995). S. cepa has caused a poisoning in one man in the US, who took a bite from a fresh specimen, having read that 'all puffballs' are edible. The first symptoms were noted within 30 min., with gastric pains followed by weakness, nausea, muscular rigidity, and a tingling sensation over the body; 45 min. after ingestion, stomach cramps and profuse sweating were noted. After vomiting, symptoms quickly subsided, and the next day no lingering effects were present (Stevenson & Benjamin 1961). S. verrucosum has also caused gastric upset after consumption (Ott 1993), and has been reported to be psychoactive (Rätsch 1998).

Biossays by several Western researchers with the Mixtec species [L. marginatum and L. mixtecorum], as well as 8 others identified by an indigenous informant, did not result in any psychoactive effects, though some caused gastric distress (Heim 1963b; Ott 1993). Lycoperdon spp. are generally considered edible when young, before any yellowing has begun and with the interiors still white [note – the interior flesh of many Scleroderma spp. is purplish] (Benedict 1972; Phillips 1981).

The chemistry of the Lycoperdon spp. is still unknown. The spores of L. gigantea, however, have been analysed and found to contain calvacin, ergosterol, urea, amino acids and lipids (Hobbs 1995).

S. citrinum has yielded tentative indole compounds, as well as fumaric acid, linoleic acid, palmitic acid, mannitol, glycerol, glucose, fructose, maltose, ergosterol, ergosterol peroxide, 9(11)-dehydroergosterol peroxide, (23S)-lanosta-8,24-diene-3β,23-diol, and a mixture of triglycerides (Nikonorow et al. 1967; Vrkoč et al. 1976).

Lycoperdon mixtecorum has a body 2-3cm diam., subglobose, slightly flattened, abruptly constricted into a short peduncle 3-4mm long; exterior surface not echinulate but densely cobbled-pustuliform, light tan in colour; interior silky, papyraceous, smooth, straw-coloured. Peridial envelope yellowish-brown mixed with orange, covered with whitish chevelure at base. Opercule ragged. Gleba loosely spongy, grey-tawny to slightly violet, capillitium filaments straight, irregular, 2-6μ long. Sterile base slightly developed, lemon-yellow to almost orange, cellules relatively large, 2-3mm, radially oriented. Spores brownish tawny with subtle violet tinge, spherical, 7.8-10μ including sculpturing, muricate-winged, presenting 5 distinct membranes covered with mesh of incomplete, unequal, pale threads.

On ground in light forest and pastures, 2000m and above; Oaxaca, Mexico, south around San Miguel (Schultes & Hofmann 1980, 1992).

When hunting for puffballs, it is important to remember that some species may resemble fruiting bodies of toxic **Amanita** spp. in the unopened 'egg' stage.

LYCOPODIUM and related genera

(Lycopodiaceae)

Lycopodium affine *Grev. et Hook. non. Bory* **(L. blepharodes** *Maxon***; Huperzia affinis** *Trevis***; H. blepharodes** *(Maxon) Holub***; Urostachys affinis** *(Grev. et Hook.) Nessel***; U. blepharodes** *(Maxon) Herter***; U. involutus** *Herter ex Nessel***)** – condorillo

Lycopodium clavatum *L.* **(L. aristatum** *Humb. et Bonpl. ex Willd.***; L. eriostachys** *Fée***; L. piliferum** *Raddi***; L. preslii** *Grev. et Hook.***; L. serpens** *C. Presl.***; L. trichiatum var. desvauxianum** *Spring.***; L. trichophyllum** *Desv.***; Lepidotis clavata** *(L.) P. Beauv.***)** – stag's horn clubmoss, snake moss, wolf claw, devil's claw, devil ash, spirit herb, keulenbärlapp, hexenkraut ['witch herb'], hexenmehl [referring to spores – 'witch flour'], hexenmoos, hexenstaub, hexenstupp, hexentanz, drudenkraut ['druid herb'], druid foot, druid flour, ground pine, running pine, vegetable sulphur, moriri-wa-mafika, boriba-bo-boholo, shen jin cao, trencilla verde, lahare jhyau, nagbeli, melam mendo

Lycopodium complanatum *L.* **(Diphasiastrum complanatum** *(L.) Holub***; Diphasium complanatum** *(L.) Rothm.***; Lepidotis complanata** *(L.) P. Beauv.***; Stachygynandrum complanatum** *(L.) C. Presl.***)**

Lycopodium flabelliforme *(Fernald) Blanch.* **(L. complanatum var. flabelliforme** *Fernald***; L. digitatum** *Dill.***; Diphasiastrum digitatum** *(Dill.) Holub***)**

Lycopodium gnidioides *L. f.* **(L. flagelliforme** *Schrad.***; L. funiculosum** *Lam.***; L. pinifolium** *Kaulf.***; Huperzia gnidioides** *(L. f.) Trevis***; Trichomanes bradei** *H. Christ.***; T. diaphanum** *Kunth***; Urostachys gnidioides** *(L. f.) Herter ex Nessel***; Vandenboschia diaphana** *(Kunth) Copel.***)** – tsilaky

Lycopodium lucidulum *Michx.* **(Huperzia lucidula** *(Michx.) Trevis***; Urostachys lucidulus** *(Michx.) Nessel***)**

Lycopodium magellanicum *(P. Beauv.) Sw.* **(L. clavatum var. fastigiatum** *(R. Br.) Benth.***; L. clavatum var. magellanicum** *(P. Beauv.) Hook.***; L. fastigiatum** *R. Br.***; L. pichinchense** *Hook.***; L. spurium** *Willd.***; Austrolycopodium magellanicum** *(P. Beauv.) Holub***; Lepidotis magellanica** *P. Beauv.***)** – condoro, trencilla del lago ['trencilla ('small plait') of the lake'], mountain clubmoss

Lycopodium obscurum *L.* **(L. dendroideum fo. strictum** *Milde***; L. obscurum fo. strictum** *Nakai ex H. Hara***)**

Lycopodium pallescens *C. Presl.* **(L. cordifolium** *Hort. ex Spring***; L. cuspidatum** *Link***; Selaginella albo-marginata** *Fée ex Foum***; S. avilae** *Klotzsch ex Kunze***; S. cuspidata** *(Link) Link***; S. densifolia** *Klotzsch***; S. dentifolia** *Klotzsch ex Aberle***; S. elongata** *G. Schneider***; S. emiliana** *Bull***; S. incana** *Spring***; S. nidus-avis** *Ezcurdia***; S. pallescens** *(C. Presl.) Spring***; S. reticulata** *Klotzsch***; S. sulcangula** *Spring***)** – moss fern, false arbor-vitae fern, sweat plant, njule

Lycopodium phlegmaria *L.* **(Huperzia phlegmaria** *(L.) Rothm.***; Lepidotis phlegmaria** *(L.) P. Beauv.***; Phlegmariurus phlegmaria** *(L.) Holub***; Urostachys phlegmaria** *(L.) Herter ex Nessel***)** – tasselled clubmoss, common tassel fern, coarse tassel fern

Lycopodium reflexum *Lam.* **(L. bifidum** *Humb. et Bonpl. ex Willd.***; L. eversum** *Poir***; L. reflexum** *Willd.***; L. reflexum var. densifolium** *Baker***; L. reversum** *C. Presl.***; L. squarrosum** *Sw. non Forst***; Huperzia reflexa** *(Lam.) Rothm.***; H. reflexa** *(Lam.) Trevis***; Plananthus reflexus** *(Lam.) P. Beauv.***; Urostachys reflexum** *(Lam.) Herter***)** – condoro

Lycopodium rupestre *L.* **(Bryodesma rupestre** *(L.) Soják***; Selaginella rupestris** *(L.) Spring.***; Stachygynandrum rupestre** *(L.) P. Beauv.***)** – rock spikemoss, wild turnip, hodzo

Lycopodium sabinaefolium *Willd.* **(Diphasiastrum sabinifolium** *(Willd.) Holub***)**

Lycopodium saururus *Lam.* **(L. andinum** *Rosenst.***; L. crassum** *Humb. et Bonpl. ex Willd.***; Huperzia saururus** *(Lam.) Trevis***; Urostachys saururus** *(Lam.) Herter***)** – condór misha, hierba del condór

Lycopodium selago *L.* **(Huperzia selago** *(L.) Bernh. ex Schrank et Mart.***; Plananthus selago** *(L.) P. Beauv.***; Urostachys selago** *(L.) Herter***)** – wolf's foot clubmoss, hexenkraut, devil clover, selago, fir selago, tannenbärlapp, bärlappgewächs, heckenysop, agwo, otuen, ude

Lycopodium serpens *Desv.* **(L. plumosum** *Lunan***; Lycopodioides serpens** *(Desv.) Kuntze***; Selaginella argentea** *Veitch***; S. brittoniorum** *Hieron.***; S. jamaicensis** *Hort. ex A. Br.***; S. mutabilis** *Hort. ex A. Br.***; S. scalariformis** *Spring***; S. serpens** *(Poir.) Spring***; S. variabilis** *(Hook.) Hort. ex A. Br.***; S. varians** *Hort. ex A. Br.***)** – snake Selaginella, agwo elili

Lycopodium serratum *Thunb. ex Murr.* **(L. sargassifolium** *Liebm.***; Huperzia serrata** *(Thunb. ex Murr.) Rothm.***; H. serrata** *(Thunb. ex Murr.) Trevis***; Urostachys serratus** *(Thunb. ex Murr.) Herter***)** – quian ceng ta, weipo

Lycopodium squarrosum *G. Forst.* **(Huperzia squarrosa** *(Forst.) Rothm.***; H. squarrosa** *(L.) Trevis***; Phlegmariurus squarrosus** *(Forst.) Löve et Löve***; Plananthus squarrosa** *(Sw.) P. Beauv.***; Urostachys squarrosus** *(Forst.) Herter***)** – water tassel, water tassel fern, rock tassel fern, yeng yeng madep

Lycopodium tetragonum *Hook. et Grev.* **(L. catharticum** *Hook.***; Huperzia tetragona** *(Hook. et Grev.) Trevis***; Urostachys tetragonus** *(Hook. et Grev.) Nessel***)** – condorillo de quatro filos

Lycopodium tristachyum *Pursh* **(Diphasiastrum tristachyum** *(Pursh) Holub***; Diphasium tristachyum** *(Pursh) Rothm.***)**

Lycopodium spp., Huperzia spp. (probably also **Copodium spp., Diphasiastrum spp., Diphasium spp., Lepidotis spp., Lycopodiastrum spp., Lycopodiella spp., Palhinhaea spp., Phlegmariurus spp., Phylloglossum spp., Plananthus spp., Selaginella spp., Selago spp.** and **Urostachys spp.**, which have been classified in **Lycopodium** by some authors**)** – clubmoss, condor plant, cóndor, condoro, condorillo, hierba de condorillo, cóndor purga, hornamo lirio, hornamo loro, huaminga, huaminga misha, huaminga oso ['bear huaminga'], trenza amarilla ['yellow braid'], trenza shimbe, bärlapp

The club mosses, a group of very similar plants distributed over much of the world, are quite obscure when it comes to their psychoactive properties. L. clavatum is probably the most widely used for medicinal purposes – as well as being an antispasmodic sedative, it has been used to treat kidney diseases and urinary disorders, lung diseases [such as bronchitis], skin diseases, constipation and rheumatism, and is an emmenagogue, demulcent, emetic and diuretic. Its spores are used for dusting pills. Blackfoot Indians inhaled the spores to stop nose-bleeds, and dusted them on cuts to staunch bleeding. The Chinese decoct it to treat disorders of the nervous system, arthritis and muscular rigidity. Its spores, 'explosive' when lit, have been added to fireworks and used in theatrical lighting. Some of the Germanic common names of this and other Lycopodium spp., involving the prefix 'hexen' or 'druden', may betray a past knowledge of psychotropic properties and related magical use. L. cernuum is used in broadly similar ways to L. clavatum, as well as being used as a charm in Surinam (Ansari et al. 1979; Bremness 1994; De Vries 1991; Huang 1993; Samorini & Festi 1999; Watt & Breyer-Brandwijk 1962). In Nepal, L. clavatum, L. cernuum, L. hamiltonii, L. serratum and L. subulifolium are associated with Vishnu, and are used as garlands in religious celebrations and for honoured guests. They are believed to give protection from witches (Müller-Ebeling et al. 2002; Rätsch 1998).

L. gnidioides is shade-dried and smoked in Madagascar, to bring about "ebriety accompanied by oneiric hallucinations similar to those produced by Indian hemp [**Cannabis**]" (Boiteau 1967; Samorini & Festi 1999). The Suto of southern Africa smoke L. clavatum with L. rupestre to relieve headaches (Watt & Breyer-Brandwijk 1932, 1962). L. rupestre [now generally known as Selaginella rupestris (Selaginellaceae)] is used in local folk medicine in India to treat epilepsy, and the smoke of the leaves apparently has a 'narcotic' effect (Chakravarthy et al. 1981). The Jindwes of Zambia prepare an ointment from the powdered rhizome, to treat venereal sores (Watt & Breyer-Brandwijk 1932). In s. Nigeria, L. pallescens [now generally known as Selaginella pallescens] rhizomes are infused and drunk to relieve insomnia; the crushed leaves are applied externally for rheumatism. In the same region, L. serpens [now generally known as Selaginella serpens] is cultivated near houses to repel evil spirits (Nwosu 2002). In Colombia and Ecuador, unidentified Selaginella spp. are added to a 'curare' arrow poison for killing birds, made also from Schoenobiblus peruvianus (Schultes & Raffauf 1990).

L. selago, which is widespread in the northern hemisphere, was an important herb used by the Druids as a protective amulet. Its collection was governed by special ritual, similar to that used for collecting mistletoe [see *Endnotes*]. The herb was so revered, it was sometimes referred to as 'God's gift'; in Wales today, the herb is still known as 'Gras Duw', or 'God's grace' (Rätsch 1998). In s. Nigeria, the plant is hung on doors to repel evil spirits (Nwosu 2002). Emboden referred to its 'narcotic' properties, stating that 3 stems, each a few inches long, induce a mild hypnotic state, while 8 will result in a stupor or coma (Emboden 1979a). It is capable of causing vomiting, dizziness, collapse and unconsciousness (Rätsch 1998).

A Lycopodium sp. known as 'condorillo' was reported to sometimes be brewed with 'San Pedro' [**Trichocereus** pachanoi] and **Brugmansia** arborea, in Peru (De Rios 1977). Further investigation has shown that in north Peru, Lycopodium spp. are commonly known by names derived from the word 'condór', such as 'condoro' and 'condorillo'. L. affine, L. reflexum, L. saururus and L. tetragonum are other species known to be consumed with San Pedro. When L. saururus ['condór misha'] or other Lycopodium spp. are taken with San Pedro, the plant spirit appears to the shaman as a condor. This spirit may undertake journeys, counteract harmful charms, retrieve the lost 'shadow soul' of patients, and perform other duties on behalf of the shaman. One researcher was told by a herb seller in Trujillo [Peru] that 'trenza shimbe', a herb resembling 'condór misha', improves the 'visionary view' when taken with San Pedro. Rätsch was also told by a herb seller in a Chiclayo [Peru] 'witches market' that 'condoro', a plant appearing to be L. magellanicum, is a 'hallucinogen', particularly if taken with San Pedro (Rätsch 1998). L. reflexum is also said to be used magically against "ritual witchcrafts". In n.e. Peru, two unidentified Huperzia spp. ['cabello del bosque' and 'huaminga'] are used medicinally, the former as a hair tonic and the latter as a strong purgative and vermifuge (De Feo 2003).

In Russia, L. annotinum is decocted as a contraceptive (Brondegnard 1973). L. serratum is used in TCM to treat memory deficits in the aged, and *huperzine A* isolated from the herb has been used to treat Alzheimer's Disease and myasthenia gravis (Liu et al. 1986; Tang et al. 1994). At Mt. Hagen, Papua New Guinea, it is used as a laxative which 'disperses the spell of death' (Stopp 1963).

The Australasian L. phlegmaria has been reputed in Queensland [Australia] to have aphrodisiac properties (Bailey 1880). The dried herb is psychoactive smoked in small amounts in a water-pipe, producing a short-lived **Cannabis**-like high. The dried herb seems to lose potency after a few months of storage (pers. exp.). Nkopo villagers from Papua New Guinea rub L. squarrosum on their bodies in order to enter a sleep-like state, in which it is hoped a bush spirit will come and give the person a song endowed with spiritual significance, which must be learnt as soon as one awakens (Schmid 1991).

A friend ingested a decoction made from 4tsp dried L. squarrosum, simmered in 1 cup of water for 5min., and steeped for a further 10min; half of the decoction was drunk, the other half drunk 1hr later. The brew had a strong fishy odour, but was easy to drink. Initially, a "subtle dreamy ambience" was felt, accompanied by mild nausea and diarrhoea, and a hot forehead; he also reported a "sort of watery pressure in the head". Several bouts of vomiting, of varying intensity, ensued over the first few hours. Mild visual distortions were observed in the reflection of light from curved glass or moving water, and the "surfaces of things smoodged a bit...Everything became a tinge Escheresque" [in reference to the famous artwork of M.C. Escher]. He reported a "blobby sort of trippiness, like [a] big soft forcefield holding energy into myself...Unfortunately concern about keeping still to prevent nausea increasing, and about the amount of poisoning [felt a tinge of pain in right kidney], were predominant over the trippy impact. Slight nausea and trippiness still present 12hrs later. The high seemed like when you trip during a heavy flu, and also like mugwort" [**Artemisia** vulgaris] (Wonderfeel pers. comm. 1998).

The genus Lycopodium contains a unique class of alkaloids related to the quinolizidines. Most of them have in common $C_{16}N$, $C_{16}N_2$, or $C_{27}N_3$ in their chemical formulae (MacLean 1985). Some of these alkaloids have shown pressor effects in animals, as well as causing uterine contractions and paralysis (Manske 1955). Nervous system paralysis has only been demonstrated in frogs; in mammals, however, clavatine, clavatoxine, and lycopodine have been shown experimentally to act as respiratory stimulants (Watt & Breyer-Brandwijk 1962). *Huperzine A* [selagine] and huperzine B have been found in some species. These alkaloids act as potent inhibitors of the enzyme acetylcholinesterase [AChE; see *Influencing Endogenous Chemistry*] (Ayer et al. 1989; Liu et al. 1986; Tang et al. 1994), with *huperzine A* also antagonising NMDA receptors (Zhang & Hu 2001). Other Lycopodium alkaloids have shown similar activity, though none as potently as the *huperzine*s, according to Tori et al. (2000), who refer to Ayer et al. (1994) and Liu et al. (1986), neither of which discuss the AChE-inhibitory activity of any alkaloids other than the *huperzine*s. Some

species also contain traces of *nicotine* (Manske 1955). The presence of flavonoids is widespread in the Lycopodiaceae. Types normally encountered in this family are mostly flavone O-glycosides, and occasionally C-glycosylflavones (Richardson 1989).

L. annotinum has yielded *nicotine*, annotine [Lycopodium alkaloid L11], annotinine [Lycopodium alkaloid L7], acrifoline [Lycopodium alkaloid L27], O-acetylacrifoline, fawcettiine, lofoline, acetyllofoline, lycodine, lyconnotine, lycopodine, isolycopodine, lycodoline [Lycopodium alkaloid L8], obscurine, and Lycopodium alkaloids L9 and L10 (Ma et al. 1998; MacLean 1968; Manske 1955).

L. cernuum has yielded 0.06-0.07% alkaloids (Braekman et al. 1974); others found 0.01% crude bases, consisting mostly of cernuine. Also found are c.0.00001% *nicotine*, *huperzine* B, lycodoline, lucidioline, lycopodine, lyconnotine, annotinine and 0.002% lycocernuine [Lycopodium alkaloid L33] (Ma et al. 1998; Marion & Manske 1948), as well as *apigenin* C-glycosides (Richardson 1989).

L. clavatum has yielded 0.1-0.42% alkaloids. The main base present was lycopodine [c.60% of total alkaloids]; also found were traces of *nicotine*, and Lycopodium alkaloids L13 [an isomer of lycopodine], L18 and L19. Clavatine and clavatoxine were found in European plants, but were not detected in plants from Canada. Therefore, on a chemotaxonomic basis, it is believed that the specimens of this species found in Europe and North America represent differing continental varieties (Braekman et al. 1974; Marion & Manske 1944b). The clavatine content isolated by some workers was actually a complex of 3 alkaloids, consisting of the 'true' clavatine [12%], lycopodine [83%] and clavatoxine [3%] (Watt & Breyer-Brandwijk 1962). The flavonoid *apigenin*-4'-O-(2",6"-di-O-p-coumaryl-β-D-glucopyranoside) has also been found (Ansari et al. 1979), as has 48% of a fixed oil, and methylamine (Huang 1993), which, if found in L. squarrosum, may explain the 'fishy' odour of the latter herb when decocted.

L. complanatum has yielded mostly lycopodine, as well as 0.012% complanatine [as the perchlorate], obscurine, Lycopodium alkaloids L2-L5 and 0.0002% *nicotine* (Manske & Marion 1942).

L. flabelliforme has also been shown to yield *nicotine*, as well as complanatine, obscurine, lycopodine and Lycopodium alkaloids L2-L5 (Manske 1955).

L. gnidioides has yielded anhydrolycodoline, gnidioidine, lucidioline, lycoclavine, lycognidine, gnidine, gnidinine, gnidioidine and *huperzine A* (MacLean 1985).

L. lucidulum has yielded 0.23% ether-soluble bases, mostly lycopodine, as well as *nicotine*, lucidine A, lucidine B, lucidulinone, oxolucidine A, and Lycopodium alkaloids L13, L20, L21, L22, L23, L24 and L25 (Manske & Marion 1946; Tori et al. 2000).

L. magellanicum has yielded lycopodine, acetyl-dihydrolycopodine, lycodine, N-methyllycodine, clavolonine, fawcettiine, acetylfawcettiine, deacetylfawcettiine, magellanine, 5-dehydromagellanine, magellaninone, α-obscurine (Loyola et al. 1979; MacLean 1985), α-onocerin and α-onocerin diformate (Loyola et al. 1982); as L. fastigiatum, it has yielded lycopodine, dihydrolycopodine, acetyl-dihydrolycopodine, lycodine, lycodoline, anhydrolycodoline, lycoflexine, clavolonine, flabelliformine, fastigiatine, des-N-methylfastigiatine, α-obscurine and an unknown alkaloid (Gerard & MacLean 1986).

L. obscurum has yielded annotinine, lycodoline, α-obscurine, β-obscurine and *nicotine* (Willaman & Li 1970).

L. paniculatum has yielded lycopodine, dihydrolycopodine, acetyl-dihydrolycopodine, lycoclavine, deacetyllycoclavine, paniculatine, paniculine [7α-OH-acetyl-dihydrolycopodine], deacetylpaniculine, anhydrodeacetylpaniculine and flabellidine (Morales et al. 1979).

L. phlegmaria has yielded lycodoline, anhydrolycodoline, lycopodine, gnidioidine, lucidioline, lycophlegmine, lycophlegmarine, phlegmarine, N-methylphlegmarine, N,N-dimethylphlegmarine, lycoflexine, fawcettidine, epihydrofawcettidine, 8-deoxyserratinidine and 8-deoxy-13-dehydroserratinine (Buckingham et al. ed. 1994; Ma et al. 1998; MacLean 1985; Manske 1955).

L. rupestre has yielded the biflavonoid amentoflavone. The amentoflavone component of the plant was assayed in rodents, but did not show any apparent behavioural effects on the central nervous system; antispasmodic activity was observed (Chakravarthy et al. 1981). Amentoflavone is a potent ligand of brain BZ-receptors (Nielsen et al. 1988).

L. sabinaefolium has yielded 0.2% crude bases, including 0.11% lycopodine, 0.00006% *nicotine*, and Lycopodium alkaloids L13 and L26 (Marion & Manske 1946).

L. saururus has yielded 0.19-0.48% alkaloids (Braekman et al. 1974), including *huperzine A*, lycopodine, dihydrolycopodine, lycodoline, anydrolycodoline, clavolonine, fawcettiine, acetylfawcettiine, pillijanine, saururine, saururidine, sauroxine and Lycopodium alkaloid LS14 (MacLean 1985; Manske 1955).

L. selago has yielded 0.587% crude alkaloids, including 0.018-0.086% *huperzine A*, lycodoline, 0.0058% isolycodoline [pseudoselagine], 12-epilycodoline, lycopodine, 6α-OH-lycopodine, obscurine, 6β-OH-*huperzine A* and acrifoline (Ayer et al. 1989; Buckingham et al. ed. 1994; Rastogi & Mehrotra ed. 1990-1993).

L. serratum has yielded *huperzine*s A [0.001%] and B, lycopodine, lycodine, lycodoline, lucidioline [0.00015%], serratine, serratinine [0.00005%] and serratinidine (Bruneton 1995; Ma et al. 1998; Willaman & Li 1970; Zhou et al. 1993).

L. squarrosum has yielded *huperzine* B, lycopodine, lycodoline and lucidioline (Ma et al. 1998).

L. tristachyum has yielded lycopodine as the major alkaloid, as well as *nicotine*, and Lycopodium alkaloids L13, L14, and L15 (Braekman et al. 1974; Marion & Manske 1944a).

*Huperzine*s A & B are widespread in this family, as are related Lycopodium alkaloids (Ma et al. 1998).

Lycopodium phlegmaria is an epiphytic plant, rarely lithophytic or terrestrial; stems isotomously branched, branches aggregated, tufted, erect at first, becoming pendulous, branched several times, 35-90cm long; sterile portion (incl. leaves) 1.5-3cm diam.; roots in a single basal tuft, sometimes branches rooting near tips or along prostrate shoots. Leaves densely spirally arranged, coriaceous, stiff, angled at 50-70° to axis, lanceolate, attenuate, entire, shortly petiolate, twisted at base, 5-20 x 2-5mm, deep green. Transition from sterile to sporogenous zone abrupt; sporogenous zone 2-30cm x 1-2.5mm, 1-many times forked; sporophylls identical to vegetative leaves or reduced, persisting after sporangial dehiscence, ovate, acute, rounded or keeled, decussate, appressed, 1-2.5 x 1-1.5mm; sporangia ½ length of (or slightly longer than) sporophylls, axillary, reniform, isovalvate, shortly stalked; spores foveolate-fossulate.

Widespread in rainforest, usually epiphytically, sometimes on mossy rocks and banks in humus accumulations, 60-600m; Australia, tropical Africa, Asia, and Pacific; in Aust. restricted to n.e. & e.c. Qld, also cultivated (Chinnock 1998).

Plants of the Lycopodiaceae grow in a range of habitats, generally in damp or humid areas. Many of the tropical species grow epiphytically on trees in rain forest or cloud forest. Many species also grow terrestrially, on substrates ranging from disturbed soil, clay soil, sandy or peaty depressions, in rocky or gravelly places, or amongst shrubs. One exception to the requirement for continuous moisture is the African L. carolinianum, which grows in areas that are seasonally dry, and survives these periods due to its large tubers (Tryon & Tryon 1982).

Whilst some species can be easy to grow in cultivation [such as L. phlegmaria, L. proliferum, L. scariosum], others can prove difficult. For example, L. cernuum is difficult to transplant successfully, yet will grow easily once established. L. serpentinum, 'bog club-moss', will only grow well in a permanently humid environment. Another species, L. deuterodensum, is said to be "impossible to grow". Of the species which can be cultivated successfully, a coarse, well-drained soil mix is recommended, and should be kept damp, but not excessively so. Watering may be preferred by aerial misting, rather than through the roots, for semi-tropical species such as L. phlegmaria and L. squarrosum. New wire hanging baskets should be used with caution, as galvanising compounds in the metal can damage the stems and cause rot if they come into direct contact with the plant. Specimens should be situated in a protected position; these plants respond poorly to disturbance and require protection from wind and sun. In nontropical areas, a glasshouse may be required. Some species require heat in order to survive (Jones & Clemesha 1976; pers. comms.).

LYGODIUM

(Schizaeaceae/Lygodiaceae)

Lygodium venestum *Swartz* **(L. mexicanum** *Presl.***)** – rami, tchai, tchai del monte

This fern is used by the Culina and Sharanahua of Peru as an ayahuasca additive [see **Banisteriopsis**], said to increase the strength of the brew. The amount added by the Culina is a handful of the leaves. A bioassay of a Sharanahua ayahuasca brew containing this fern [as well as **Banisteriopsis** caapi and **Psychotria** viridis] resulted in strong physical side effects ["nausea, pain in the muscles, accompanied by compulsive and uncontrollable movements (swaying, hand moving), a feeling of coldness"], as well as feelings of anguish, accompanying the effects more typical of ayahuasca brewed with **Psychotria**. It was not known by the researcher involved if the Sharanahua also experience these adverse effects. Incidentally, the name 'rami' is the Sharanahua name for a "shining blue veil" which may sometimes be seen in the early stages of an ayahuasca experience (McKenna et al. 1995; Pinkley 1969; Rivier & Lindgren 1972; Schultes 1972). The Huastec Maya of Mexico use the same plant as a treatment for insanity or psychological disorders (Ott 1993).

In China, the whole plant of L. japonicum ['Japanese climbing fern'] is used in doses of 15-60g as 'ching-sha-teng' or 'jing-sha-deng' ['gold sand vine'] to treat delirium, high fever, pneumonia, coughing with blood, toothache, hepatitis, and gonorrhoea. It also acts as a sedative. The spores ['hai-chin-sha' or 'hai-jin-sha'] are used in a dose of 6-12g to treat urinary disorders (Chin & Keng 1990; Hsu et al. 1986). In s. Nigeria, L. flexuosum ['agbiligbi', 'usehe'] leaves are infused and taken to treat infertility in women (Nwosu 2002).

Chemistry of ferns is quite obscure, though this genus is known to yield aliphatic and triterpene hydrocarbons (Schultes & Raffauf 1990). L. venestum contains compounds with antifertility actions (McKenna et al. 1995), and L. japonicum contains flavonoids (Hsu et al. 1986).

Lygodium venestum is a terrestrial fern; stem short to long-creeping, slender, frequently branched, protostelic, bearing short trichomes and few to many fibrous roots. Leaves partially dimorphic, fertile portions with marginal lobes, or somewhat contracted and wholly fertile, sometimes with a different architecture than the sterile, close or rather widely spaced, c.1-10m or more, climbing, widely alternately pinnate, glabrous to somewhat pubescent, pinnae short-stalked, pseudodichotomously branched with an arrested bud in the axil; each primary pinna-branch pinnate, veins free, the pinnules stalked, except sometimes near the apex of the primary branch; sterile pinnules lobed or pinnate, palmately lobed at base. Sporangia borne separately on marginal lobes of a pinna-segment or on a wholly fertile segment, each covered by a laminar outgrowth (flange); spores tetrahedral-globose, trilete, the laesurae c.3/4 the radius, surface with spherical deposition, the distal face often verrucate and the proximal one with a prominent ridge connecting the ends of the laesurae, or rugose to reticulate.

In open forest, especially along borders where the climbing leaves can reach well-lit situations, sometimes in rainforests, but more commonly in gallery forest, shrubby savannahs or along borders of streams or river banks, frequently in disturbed spots; Central & S. America (Tryon & Tryon 1982).

MACROPIPER

(Piperaceae)

Macropiper excelsum ssp. excelsum *(Forst. f.) Miq.* **(Piper excelsum** *Forst. f.***)** – pepper tree, kawakawa, 'Maori kava'
Macropiper excelsum ssp. peltatum *Gardner*
Macropiper excelsum ssp. psittacorum *(Endl.) Laing* **(M. excelsum var. majus** *(Cheesem.) Allan comb. nov.***; Piper excelsum var. major** *Cheesem.***; P. psittacorum** *Endl.***)**
Macropiper latifolium *(L. f.) Miq.* – false kava

M. excelsum was thought to have been adopted by the Maoris of the north island of New Zealand about 1,000yrs ago, due to its apparent similarity to the 'true kava', **Piper** methysticum [see **Piper 2**], which is also known as 'kawakawa' or 'kavakava'. A beverage of this name was prepared from the roots and leaves, and used in religious rites. The root has been used to treat urinary disorders, and the leaf and bark treated gonorrhoea, stomach pain and toothache, also acting as an anthelmintic. Leaves could also be infused as a tonic, or applied topically to swelling or rheumatism. The fruits were considered to have the most potent properties, but were used less often. The plant acts as a stimulant and aphrodisiac, and slightly excites the salivary glands, kidneys and bowels. New Zealand Parliament banned shamanic practices in 1907, and partially for this reason, further knowledge regarding the past use of magical plants in New Zealand remains obscure (Bock 2001; Brooker et al. 1987).

Today, M. excelsum is cultivated, and the dried leaf is sold in teabags by some New Zealand herbalists. The apparently "insipid" tea is said to "clear the head, cleanse the body and produce a feeling of wellbeing and relaxation without drowsiness" (Low et al. ed. 1994).

M. excelsum leaf has yielded 0.1% essential oil, which consisted of 41.3% *myristicin*, 3.1% *elemicin*, and lesser amounts of *pinene*, phellandrene, aromadendrene and cadinene (Bock 2001); leaf has also yielded the lignans (+)-excelsin, (+)-epiexcelsin, (+)-demethoxyexcelsin and (+)-diayangambin (Russell & Fenemore 1973).

M. latifolium essential oil contains predominantly β-*asarone* (Lebot et al. 1992). The leaves are peppery to the taste and only slightly numbing; the root bark has a "VERY hot taste", and has numbing properties stronger than those of 'true' kava [see **Piper 2**] (Torsten pers. comm. 2001).

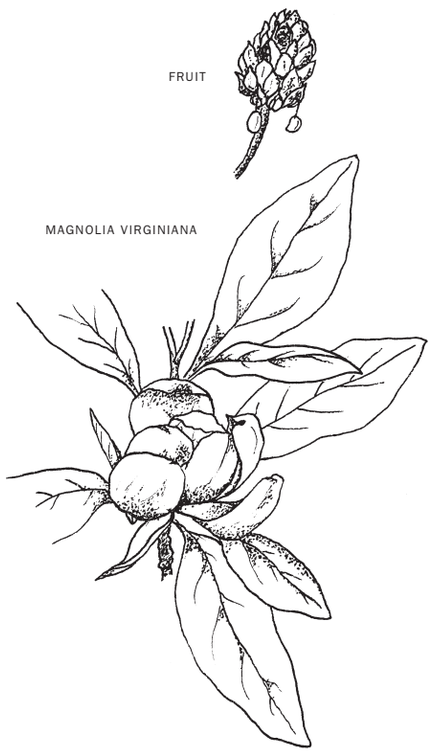
Macropiper excelsum ssp. excelsum is an aromatic shrub or tree to 6m tall; branches +- zig-zagging, jointed and swollen at nodes, dark. Leaves opposite or alternate, entire, subcoriaceous, dark- to yellowish-green, 5-10 x 6-12cm, broad-ovate to suborbicular, cordate at base, sinus narrow to open, rather abruptly narrowed to obtuse at apex, 5-7(-9)-subpalmately nerved; petiole 1-4cm long; stipules adnate. Flowers minute, sessile, very close-set, in axillary, unisexual, bracteated spikes; spikes solitary or paired, 2-8cm long on peduncles +- 1cm long; bract orbicular-peltate; male with 2(-3) stamens; anthers 2-celled, cells distinct. Female with 3(-4) stigmas; ovary superior, 1-celled; ovule 1, basal. Fruit a small drupe, very close-set, 2-3mm diam., +- angled; exocarp succulent, yellow to orange, broadly obovoid. Fl. & fr. all year.

Lowland forest; north island, south island s. to Banks Peninsula and Okarito, also on Chatham Island.

M. excelsum ssp. psittacorum differs by having leaves 10-16 x 11-20cm, 9-nerved; spikes up to c.15cm long (Allan 1961). Kermadec Is., Lord Howe Is., Norfolk Is., Three Kings, Poor Knights, Little Barrier, Tiritiri, Mayor Is., and other small islands off the coast of New Zealand's north island (Allan 1961; Bock 2001).

MAGNOLIA

(Magnoliaceae)



Magnolia biondii *Pamp.* **(M. aulacosperma** *Rehder et Wilson***; M. biondii fo. purpurascens** *Law et Gao***; M. conspicua var. fargesii** *Finet et Gagnep.***; M. denudata var. fargesii** *(Finet et Gagnep.) Pamp.***; M. fargesii** *(Finet et Gagnep.) W.C. Cheng***)** – xin yi hua
Magnolia dealbata *Zucc.* **(M. macrophylla var. dealbata** *(Zucc.) D.L. Johnson***)** – elexochitl
Magnolia denudata *Desr.* **(M. conspicua** *Salisb.***; M. heptapetala** *(Buc'hoz) Dandy***; M. obovata var. denudata** *(Desr.) DC.***; M. yulan** *Desv.***; Lassonia heptapetala** *Buc'hoz***)** – xin yi hua
Magnolia kobus *DC.* **(M. praecocissima** *Koidz.***; M. tomentosa** *Thunb.***; Buergeria obovata** *Sieb. et Zucc.***; Yulania kobus** *(DC.) Spach***)** – kobushi
Magnolia liliflora *Desr.* **(M. quinquepeta** *(Buc'hoz) Dandy***; Lassonia quinquepeta** *Buc'hoz***)** – xin yi hua
Magnolia officinalis *Rehder et E.H. Wilson* **(M. biloba** *(Rehder et Wilson) Cheng***; M. officinalis ssp. biloba** *(Rehder et Wilson) Cheng et Law***; M. officinalis var. biloba** *Rehder et Wilson***; M. officinalis var. pubescens** *C.Y. Yeng***)** – Chinese magnolia, chuan how-pow, hou po
Magnolia salicifolia *Maxim.* – tamushiba

Magnolia tripetala *L.* **(M. umbrella** *Lamarck***)**
Magnolia virginiana *L.* **(M. australis** *Ashe***; M. australis var. parva** *(Ashe) Ashe***; M. fragrans** *Raf.***; M. glauca** *(L.) L.***; M. glauca var. longifolia** *Pursh***; M. glauca var. pumila** *Nutt.***; M. virginiana ssp. australis** *(Sarg.) Murray***; M. virginiana var. australis** *Sarg.***; M. virginiana var. glauca** *L.***; M. virginiana var. parva** *Ashe***)** – sweet bay, swamp bay, white bay, white laurel, red laurel, sweet Magnolia, swamp sassafras, beaver tree

These Magnolia spp., large trees with splendid flowers, have similar medicinal and intoxicating properties, generally as aromatic tonic stimulants or narcotics.

M. dealbata has been proposed to have been the Aztec inebriant 'poyomatli' (Diaz 1979), yet it is likely that the true identity of poyomatli will never be known with certainty. The Cherokee use M. acuminata and M. macrophylla as analgesics (Hamel & Chiltoskey 1975). The Rappahannock snuff leaves and bark of M. virginiana as a 'mild dope' (Ott 1993). The odour of the flowers of this species has, on occasion, caused fainting and difficulty in breathing [presumably with over-exposure]. The bark of M. tripetala has been chewed as a tobacco substitute [see **Nicotiana**] by at least one person, who thus succeeded in breaking his tobacco habit. In N. America, the barks of Magnolia spp. [harv. spring and summer] were once widely used as bitter tonics, with diaphoretic and possibly antiperiodic effects, though they are rarely used any more in western medicine (Felter & Lloyd 1898).

M. officinalis is revered in TCM for its bark [dose – 6-10g], which is a tonic aphrodisiac, and is used to treat neurosis, colds, coughs, vomiting, asthma, diarrhoea, peptic ulcers and stomach spasms. Its antiseptic properties are effective against typhus, malaria and salmonella; the bark also has a muscle-tranquillising component (Bremness 1994; Chin & Keng 1990; Keys 1976; Watanabe et al. 1983). M. salicifolia flower buds ['shin-i'] are used in Japan to treat headache and nasal congestion (Watanabe et al. 1981). An extract of the bark from M. obovata [closely related to M. denudata] has shown sedative effects in mice (Macrae & Towers 1984a).

M. biondii, M. denudata and M. liliflora flower buds, used in TCM, contain *eugenol*, *safrole*, *estragole* and *anethole*. Leaves yielded salicifoline [3-OH-4-MeO-N,N,N-trimethyl-*phenethylamine*] and the aporphine magnocurarine. M. liliflora is said to be incompatible with **Acorus** gramineus (Huang 1993; Keys 1976; Tomita & Nakano 1957).

M. grandiflora bark has yielded candicine [4-OH-N,N,N-trimethyl-*phenethylamine*], salicifoline and the aporphine magnoflorine [thalictrine] (Tomita & Nakano 1957); wood has yielded N-nor-*nuciferine*, anonaine, anolobine and liriodenine; leaves yielded only anonaine and liriodenine (Tomita & Kozuka 1967).

M. kobus bark has yielded [w/w] 0.214% salicifoline (Tomita & Nakano 1952b).

M. obovata bark has yielded magnocurarine (Tomita & Nakano 1957), as well as neolignans similar to those in **Virola** spp. (Macrae & Towers 1984a).

M. officinalis bark has yielded the neolignan derivatives magnolol and honokiol, which caused sedation, ataxia and muscle relaxation in mice, in doses of 50-500mg/kg [i.p.] (Watanabe et al. 1983); honokiol also stimulated K+-evoked *acetylcholine* release in rat hippocampus (Tsai et al. 1995).

M. salicifolia bark yielded [w/w] 0.016% salicifoline, as well as magnocurarine (Tomita & Nakano 1952a, 1957); flower buds yielded the benzyltetrahydroisoquinolines d-coclaurine [sedative; inhibits *dopamine* uptake in rat iris] and d-reticuline [sedative] (Watanabe et al. 1981); leaves and small branches yielded an essential oil containing 73% *anethole*, 7% anisaldehyde, 1.3% 1,8-cineole, 3% hydrocarbon and traces of *citral* (Matsuura & Watanabe 1953).

M. sprengeri has yielded N,N-dimethyl-3-MeO-*tyramine* (Lundstrom 1989).

M. stellata bark has yielded salicifoline (Tomita & Nakano 1957).

M. virginiana leaves have yielded the neolignans magnolol, MeO-hinikol and biphenyl ether. Flowers yielded 1.16% 4,4'-diallyl-2,3'-dihydroxybiphenyl ether, 0.11% 3,5'-diallyl-2',4-dihydroxybiphenyl, 1.66% 5,5'-diallyl-2,2'-dihydroxybiphenyl and 0.42% 3,5'-diallyl-2'-OH-4-MeO-biphenyl (Chandra & Nair 1995). In a broad alkaloid screening, stem and leaf tested positive (Fong et al. 1972).

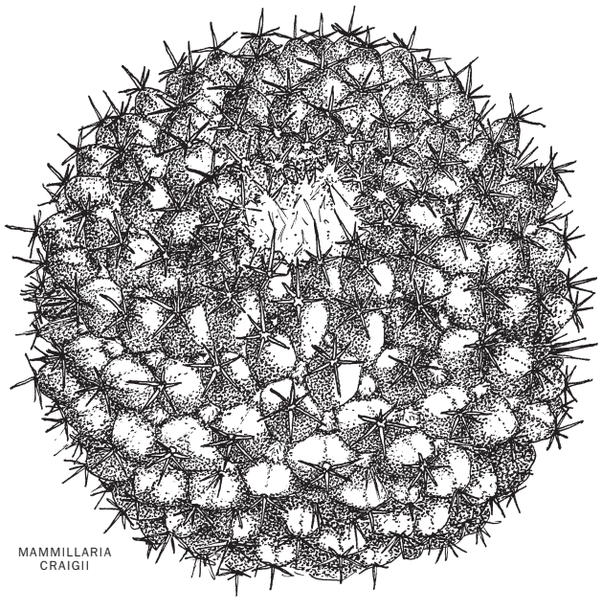
Aporphine alkaloids are common in the genus Magnolia – including nor-*nuciferine*, asimilobine, anonaine, glaucine, norglaucine, oxoglaucine, obovanine, liriodenine, lanuginosine, norushinsunine, N-methyllindcarpine and N,N-dimethyllindcarpine (Guinaudeau et al. 1975).

Magnolia virginiana is a tall shrub or slender tree to 20m tall. Leaves scattered on the twigs, coriaceous, deciduous in north, evergreen in south, oblong to elliptic or sometimes oblanceolate, 8-15cm long, 1/3-1/2 as wide, obtuse, base acute to broadly rounded, strongly glaucous and finely pubescent beneath; stipules completely encircle stem at base of leaf, early deciduous, leaving a scar. Flowers fragrant, white, subglobose, c.5cm diam., or in age more widely expanded; perianth of 9-15 similar or scarcely differentiated segments in 3-5 circles; petals 9-12, coriaceous, obovate, concave, 3-5cm long, forming a subglobose flower; stamens many, spirally arranged; pistils many, spirally arranged, on an elongate receptacle, ripening into red or brown cone-like fruits; anthers introrse. Ovaries separately dehiscent at maturity, exposing the seeds; ovules 1-2 in each ovary. Seeds remaining attached by slender threads for some time after dehiscence. Fl. May-Jul.

Wet woods and margins of swamps; e. Massachusetts, Long Island, New Jersey to Texas and Arkansas, mostly on the coastal plain, but extending inland to Pennsylvania (Gleason 1952).

MAMMILLARIA [including Dolicothele]

(Cactaceae)



MAMMILLARIA CRAIGII

Mammillaria craigii *Lindsay* – peyote de San Pedro, wichurí, wichuríki, witkulíki, biznaga
Mammillaria elongata *DC.* **(M. intertexta** *DC.***; M. subcrocea** *DC.***; M. tenuis** *DC.***; Echinocactus densus** *Steud.***; Neomammillaria elongata** *(DC.) Br. et R.***)** – golden star
Mammillaria grahamii *Engelmann* **var. oliviae** *(Orcutt) Benson* – híkuli, híkuri, peyote
Mammillaria heyderi *Mühl.* **(Cactus heyderi** *Kuntze***; Neomammillaria heyderi** *(Mühl.) Br. et R.***)** – wichurí, wichuríki, witkulíki, biznaga, biznaga de chililos
Mammillaria longimamma *DC.* **(Dolicothele longimamma** *(DC.) Br. et R.***)** – peyotillo, peyote
Mammillaria pectinifera *(Ruempler) Weber* **(Pelecyphora pectinata** *B. Stein***; Solisia pectinata** *(B. Stein) Br. et R.***)** – peyotillo, peyote, cochinito ['little pig']
Mammillaria senilis *Lodd.* **(Cactus senilis** *Kuntze***; Mamillopsis senilis** *(Lodd.) Weber***)** – cabeza de viejo ['head of the old'], chilito, biznaga de chililos
Mammillaria sphaerica *Dietr.* **(Dolicothele sphaerica** *(Dietr.) Br. et R.***)**
Mammillaria surculosa *Böed.* **(Dolicothele surculosa** *(Böed.) Buxb.***)**
Mammillaria uberiformis *(Zucc.) Br. et R.* **(M. longimamma var. uberiformis** *(Zucc.) D.R. Hunt***; Dolicothele uberiformis** *(Zucc.) Br. et R.***)**

Carl Lumholtz reported early last century that amongst the Tarahumara of n. Mexico, "High mental qualities are ascribed especially to all species of Mammillaria and Echinocactus." Plants from these genera were also mentioned by Bravo as being very important in religious rites, known as 'comitl', 'metzollin', and/or 'huiztnahuac'. Some of these plants known under the latter name were considered to be incarnations of Tlaloc (Bravo 1937; Schultes 1967a). Unfortunately, it is unclear exactly which Echinocactus spp. [see *Endnotes*] Lumholtz was referring to, and **Lophophora** williamsii was once classified as an Echinocactus.

The Tarahumara once used M. craigii and/or M. heyderi for their medicinal and psychoactive properties [some believe these to be synonymous species; some keep them separate but say that the Tarahuamara plant is actually M. craigii and not M. heyderi]. The plants are both feared and held in high regard, and must be harvested respectfully. M. craigii/M. heyderi has been used to treat headaches, earaches and deafness, by inserting the juice of the cut, despined and roasted cactus into the ear. The centre of the plant is rich in a white latex. This plant was claimed to be ingested as a stimulant for runners, and so that a shaman could "locate witch-

es and wizards by clearing his vision". The despined tops of the plants are reputed to be the most effective, and when consumed, have been claimed to send one into a sleep in which brilliantly coloured visions and shamanic voyages are experienced – or, if the consumer is not properly prepared for the experience, "it will drive him crazy". The edible fruits ['chilitos'] are enjoyed locally (Bruhn 1973; Bruhn & Bruhn 1973; Bye 1979b). M. grahamii var. oliviae is reputed by the Tarahumara to have the same effects as decribed for M. craigii, and it was ritually consumed by the shaman with other participants (Bye 1979b).

M. longimamma and M. pectinifera have also been known as 'peyote' and 'peyotillo' [see **Lophophora**] (Schultes 1937a, 1937b), though it is not known whether they have been used ritually. M. senilis has been said to be sacred to the Tarahumara, due to the respect displayed toward the plant (Bruhn 1973; Bruhn & Bruhn 1973; Bye 1979b). M. senilis might represent the 'híkuli rosapara' mentioned under **Epithelantha** (Bye 1979b). The Seri of Sonora use M. microcarpa and M. sheldoni medicinally, in common with the Tarahumara use of M. craigii/M. heyderi – the juice from the vascular bundle is given as ear drops to treat earache (Felger & Moser 1974).

M. craigii has been found to be psychoactive in human bioassays. For each person, one whole plant including the root [the 'button' being c.10cm diam., 5cm tall] was decocted and drunk; the residue was also eaten. The psychonauts who consumed this experienced a pleasant 'trip', which was compared qualitatively to a mixture of *mescaline* and MDMA (Torsten pers. comm.). Another psychonaut smoked the dried latex of this species, mixed with **Cannabis**; subjectively, the effects were compared to a combination of smoked **Salvia** divinorum and **Cannabis** (Anon. 1998). There appears to be no published chemical analysis of this species.

M. elongata yielded less than 0.004% alkaloids – 0.0009% synephrine, 0.0005% *hordenine*, and traces of β-O-methylsynephrine, *tyramine* and N-methyl-*tyramine* (West & McLaughlin 1973).

M. heyderi has yielded 0.01-0.05% alkaloids [w/w], mostly N-methyl-*DMPEA*, with smaller amounts of an unidentified alkaloid (Bruhn & Bruhn 1973). The latex was smoked with **Cannabis** as above, but no effects were noted that could not be attributed to the **Cannabis** (Anon. 1998).

M. longimamma has yielded 0.43% d,l-synephrine, as well as 0.012% *normacromerine*, 0.00037% longimammine [may = longimammidine], 0.0019% longimammosine [6-OH-THIQ], 0.0019% longimammidine [8-OH-2-methyl-THIQ], 0.0028% longimammatine [6-MeO-THIQ], 0.0008% longimammamine [4,8-dihydroxy-2-methyl-THIQ] and ubine [N,N-dimethyl-β-OH-*phenethylamine*]; as well as 10.5% lipids (Kruger et al. 1977; Ranieri & McLaughlin 1975, 1976a).

M. meiacantha [= M. runyonii *(Br. et R.) Boed.*] contains an unidentified alkaloid, 0.114% acetovanillone, 0.0069% mammillarol [a triterpene] and 0.0043% ACI-9 [a steroid] (Dominguez & Pugliese 1967).

M. pectinifera has yielded 0.01-0.05% alkaloids, mostly *hordenine*, with lesser amounts of N-methyl-*tyramine* and an unidentified alkaloid (Bruhn & Bruhn 1973).

M. sphaerica has yielded [w/w] 0.0033% synephrine, 0.0038% β-O-ethyl-synephrine, 0.0155% N-methyl-*tyramine*, 0.0411% N-methyl-*phenethylamine* and 0.65% dolicotheline [N-isovaleryl-*histamine*] (Dingerdissen & McLaughlin 1973a; Dingerdissen et al. 1973). Doping with isocaproic acid caused the plant to produce N-isocaproyl-*histamine*; doping with 4(5)-aminomethylimidazole caused production of 4(5)-[N-iso-valerylaminomethyl]imidazole (Rosenberg & Paul 1973).

M. surculosa has yielded [w/w] 0.134% N-methyl-*tyramine*, 0.25% N-methyl-*phenethylamine*, 0.017% synephrine, 0.178% *hordenine*, traces of dolicotheline and an unknown imidazole (Dingerdissen & McLaughlin 1973b).

M. uberiformis has yielded synephrine, longimammine, longimammatine, uberine [5-MeO-7-OH-2-methyl-THIQ], *normacromerine*, N-methyl-*DMPEA*, N-methyl-4-MeO-*phenethylamine*, N,N-dimethyl-β-OH-*phenethylamine*, N-methyl-*tyramine* and *hordenine* (Kruger et al. 1977; Ranieri & McLaughlin 1976b).

Mammillaria craigii is a simple cactus, branching dichotomously, with a sunken, woolly apex; roots fibrous. Tubercles closely set in 13 and 21 spirals, firm in texture, light yellowish grey-green, 4-sided, sharply angled to tip, 6-7mm long, 9-10mm wide at base, with milky sap; areoles oval, 2mm long, sunken, with abundant light tan wool persisting for some time; axils with a little white wool in flowering area, but no bristles; central spines (1-)2(-3), 10-20mm long, lower longest, all slender acicular, stiff, smooth, nearly straight, upper slightly recurved, all slightly enlarged at base, brownish-golden, slightly divergent dorsally and ventrally from porrect; radial spines 7-8, 4-12mm long, upper 3 shorter, lower longest, all fine acicular, straight, smooth, mostly stiff to semiflexuous, base slightly enlarged, brownish-golden, markedly ascending. Flowers campanulate, somewhat lateral, 15-20mm long, 10-15mm wide; outer perianth segments 15, very pale greenish below, brownish-pink above, linear, tip obtuse, margins serrate and slightly ciliate; inner perianth segments deep pink, darker mid-line ventrally, linear-spatulate, tip obtuse to emarginate, margins mostly entire, sometimes serrate at tip; filaments cream to yellow to pink above; anthers sulphur-yellow; style yellow to very pale pink above; stigma lobes 7, greenish-yellow, 3mm long, slightly overtop anthers. Fruit red, clavate, 12 x 8mm, with dried perianth persisting; seeds light brown, glossy, curved pyriform with lateral hilum near base, faintly reticulate, 1 x 0.4mm. Fl. Feb.-Mar., open for 2-3 days.

In leaf mold in crevices of rocks, partial shade, in mountainous habitat c.1800m; s.w. Chihuahua, s.e. Sonora [Mexico] (Craig 1945).

MANDRAGORA

(Solanaceae)

Mandragora autumnalis *Bert.* **(M. femina** *Gersault***; M. microcarpa** *Bertol.***; M. officinalis** *Moris***; M. officinarum** *Bert. non L.***)** – mandrake, autumn mandrake, black mandrake, female mandragora, morion

Mandragora caulescens *C.B. Clarke* **(Anisodus caulescens** *(C.B. Clarke) Diels***)**

Mandragora officinarum *L.* **(M. acaulis** *Gaert.***; M. mas** *Dod.***; M. neglecta** *G. Don.***; M. officinalis** *Mill. non Moris***; M. praecox** *Sweet***; M. vernalis** *Bert.***)** – mandrake, spring mandrake, mandragora, male mandragora, mandagloire, devil's apple, love apple, circeium, merdomgia, isterung, ebrewi sanam, segken ['dog-dug'], atzmann, yabrouh, hunguruk koku, tuphac el sheitan, putrada, lakshmana, alraun, hexenkraut, galgemannlein ['little gallows man'], thjofarot

Mandragora turcomanica *Mizgir.*

Mandragora spp. – mandrake, main de gloire, madagfoire

Mandrake is an ancient and mysterious magical herb, surrounded by mythology and archaic beliefs. It has drawn reverence for its sometimes anthropomorphic root [with the powers of imagination factored in to the equation], said to contain a spirit that would kill the digger of the plant with its screams. Many rituals arose to deal with this supposed problem, and safely harvest the root, mostly involving the use of an unwitting dog to pull up the root, and 'sacrifice itself' with its supposed subsequent death. The root was not generally consumed, but instead kept as a good-luck amulet. Often the more anthropomorphic roots were dressed in tiny clothes and cared for [as 'alraun' – 'elf-whisper'], with the attendant belief that failure to do so would bring disastrous misfortune.

The ancient Greeks used it in wine as an aphrodisiac, stupefacient, and surgical anaesthetic. Dioscorides referred to a variety of mandrake which was particularly potent, known as 'morion', which may have been M. autumnalis. It was commonly believed in many areas that mandrake fruits could enable an infertile woman to bear a child. Mandrake fruit [as 'dudaïm' in original texts] is said to have been used by Rachel in the Bible [Genesis 30:14-15] to help her conceive. The plant was also used in wine or beer [see *Methods of Ingestion*] by the ancient Egyptians as an aphrodisiac and stupefacient. In legend, Ra used a beer fortified with mandrake and human blood to placate the ravening lion-goddess Sekhmet, and turn her [after a long sleep] into the love-goddess Hathor (Emboden 1979a; Duke 1983; Rätsch 1990, 1992; theobromus pers. comm.; Thompson 1968; Zohary 1982). M. turcomanica has been suggested as a potential candidate for the identity of 'haoma', and perhaps also 'soma' [see **Peganum**, **Amanita**], though this is based on scanty evidence (Ott 1998b).

By the Middle Ages, knowledge of the properties of mandrake had spread to practitioners of magic and herbalism in Europe and China. The plant has been an ingredient in witches potions and 'flying ointments'. Even today in Romania, the ritual collection and use of mandrake as a magical aphrodisiac continues, and the Bedouins of Israel hold it sacred. Near Mt. Lebanon, the fruits are known as 'baidh ul-jinn' ['eggs of genii'], alluding to knowledge of the properties of the plant. In Sikkim, the root of M. caulescens is reportedly used in 'magic rites'. In Armenia, the smoke from burning mandrake is inhaled to cure insanity. In India, M. officinarum root, as 'lakshmana' [see also **Calonyction**], is regarded as an aphrodisiac and 'promoter of conception'. As long as the mandrake has been sought after for its properties, various plants with anthropomorphic roots, or with roots carved or otherwise manipulated to replicate an approximation of human form, have been sold to the unwitting as true mandrake. Some of these plants have included Allium victoralis, Bryonia dioica ['bryony'], Podophyllum pentatum ['American mandrake', 'mayapple'] and others, which are known as 'false mandrakes' (Duke 1983; Emboden 1979a; Jackson & Berry 1979; Mehra 1979; Rätsch 1990, 1992; Schultes & Hofmann 1992; Thompson 1968).

In the late 15th century, mandrake became an ingredient in a general anaesthetic devised by an early surgeon, Hugo of Lucca. His mixture, which was soaked into a sponge for use ['spongia somnifera'], contained mandrake leaf-juice, opium [see **Papaver**], hemlock [see **Conium**], henbane [see **Hyoscyamus**], unripe mulberry juice [see **Morus**], forest mulberry, wood ivy, water lettuce, lettuce seeds [see **Lactuca**], water hemlock seeds [Cicuta sp.; see **Conium**] and dock seeds (Thompson 1968).

Some antidotes for mandrake poisoning have been suggested in the past, however we do not know whether they are effective. One of these consisted of wormwood [see **Artemisia**], rue [Ruta graveolens – see *Endnotes*], scordium, mustard [see **Brassica**], oregano [Origanum sp. –

see *Endnotes*] and castor [Ricinus sp.], taken with vinegar and wine [see *Methods of Ingestion*] (Thompson 1968).

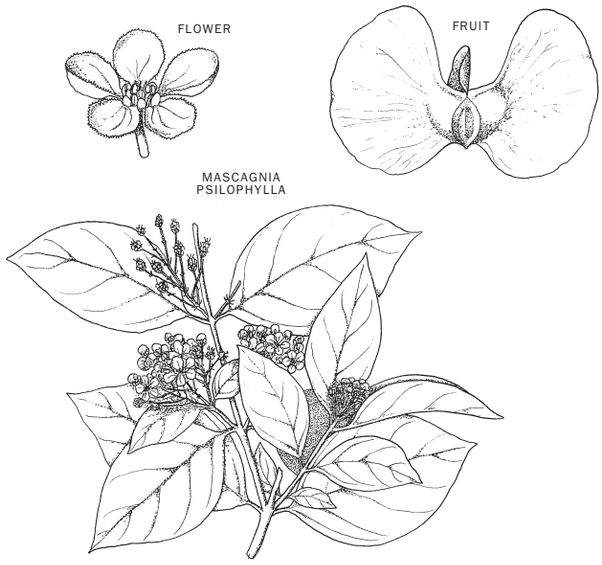
M. officinarum and M. autumnalis [and probably the whole genus] are potently psychoactive plants, and attempted use as an aphrodisiac should be with very small doses. Their alkaloid composition appears to be virtually identical. Highest alkaloid concentrations are reported to be in the roots and fruits; roots have yielded 0.1-0.4% alkaloids, mostly *hyoscyamine*, as well as *hyoscine*, apo-*atropine*, belladonnine and traces of cuscohygrine [mandragorine; present in larger amounts in fresh roots]; 3α-tigloyloxytropane, 3,6-ditigloyloxytropane, β-methylesculetin [in fruits], sitosterol, rhamnose, glucose, fructose and sucrose have also been found in the plant (Evans 1979; Hesse 1901; Jackson & Berry 1973, 1979; Schultes & Hofmann 1980; Thoms & Wentzel 1901). M. autumnalis has been found to contain calystegines B2 and B3 in the leaves, and calystegines A3, B1, B2, and B3 in the roots [see **Convolvulus**] (Bekkouche et al. 2001).

Mandragora officinarum is a perennial herb with a stout, erect, often bifid and anthropomorphic fleshy taproot; acaulescent or with a very short stem. Leaves simple, in a dense basal rosette, petiolate, ovate to ovate-lanceolate, entire, undulate, sparsely villous on veins at least when young. Flowers hermaphrodite, solitary, axillary; pedicels usually shorter than leaves; calyx slightly accrescent, much shorter than berry, campanulate, 5-lobed; corolla campanulate, with 5 narrowly triangular lobes, plicate between the lobes, persistent, not more than 2.5cm, greenish-white; stamens 5, subexserted, inserted in lower ½ of corolla-tube, alternating with lobes; filaments villous below; anthers dorsifixed. Ovary superior, usually with 2 loculi, surrounded at base by glandular disc; style simple; stigma capitate. Fruit a globose yellow berry, becoming unilocular by the obliteration of the septum; seeds usually numerous.

N. Italy, w. Yugoslavia (Tutin et al. ed. 1964-1980), other Mediterranean countries, to North Africa.

MASCAGNIA

(Malpighiaceae)



Mascagnia glandulifera *Cuatrecasas*

Mascagnia psilophylla var. antifebrilis *(Griseb.) Nied.* **(M. psilophylla var. peruviana** *Nied.***; Banisteria antifebrilis** *Griseb.***; Cabi paraensis** *Ducke***; Callaeum antefebrile** *(Griseb.) Johnson***)** – cabí, caapueira, hayawasca, bejuco de las calenturas ['vine for fever'], shillinto

The bush M. psilophylla var. antifebrilis is reported to be used as an ayahuasca additive [see **Banisteriopsis**] in Peru, though in at least one case identification may have been in error due to a mixed collection. As Cabi paraensis, it has been reported to be used in the same way as **Banisteriopsis** near the mouth of the Amazon. When added to ayahuasca, the plant is used in order to treat difficult cases of typhus or fever. The root is used alone to treat fevers, and is taken in a cold water infusion as a vermifuge (Bristol 1966; Luna & Amaringo 1991; Schultes 1957, 1966; Schultes & Raffauf 1990). In the middle Aporis, the crushed, boiled leaves of M. glandulifera are applied as a poultice to boils and other infections (Schultes 1950). It is also suspected of being used as a yajé source-plant, in place of **Banisteriopsis** (Trout ed. 1998 – see Harv. Bot. Mus. Leaf. 26(5):177-197 [1978]).

In Brazil, Mascagnia spp. [known as 'cipó-prata'] sometimes cause fatal intoxications in cattle, with 0.5-2kg/100kg causing sudden death due to cardiac arrest (Pott & Alfonso 2000).

M. psilophylla var. antifebrilis leaves and twigs have yielded *harmine* (Mors & Zaltzman 1955).

Mascagnia psilophylla var. antifebrilis is a shrubby bush, to 5m, scrambling or climbing, branches pale brown or hoary white, to c.0.5cm diam., internodes 2-7(-13)cm long. Leaves to 3cm long, caudate-acuminate, base acute to obtuse, often narrow or inaequilateral, ovate to elliptic to subrotundate, membranaceous-chartaceous, upper side smooth, underside with 4-5 prominent primary nerves, secondary nerves parallel, slightly raised, areolate and near upper margin base spotted on both sides with 1-2 wide glands; petiole slightly puberulous, to 2cm long, sometimes below apex bi-glandulose; stipules gland-like or tubercule-like, attached on both sides at base of petiole, scarcely 4mm high. Umbels axillary, numerous, arranged in large panicles; peduncle 3-7mm long, pedicels mostly twice as long; bracts ovate, c.1.25mm, bracteoles cordate-rotund to reniform, semiamplexicaul, 1.5-2mm long; flowers 1.5cm diam.; sepals orbicular, with 8 glands, 1.5-2.25mm long; petals 5, spathulate, acute, base glandulose-fimbriate, 5-7mm diam., unguis recurved, 2mm long; anthers orbicular, 1mm diam. Style mostly sericeous, 2, posterior recurved-divergent, anterior somewhat shortly suberect. Fruit a samara, subglabrate, leathery, 3-winged; nut subglobose, 0.7-0.75cm long, areole widely ovate; lateral flange margin slightly sinuate.

Peru [Pueblo Nuevo; Tarapoto, Dep. Loreto] (Engler & Niedenzu 1928).

MAYTENUS

(Celastraceae)

Maytenus chuchuhuasha *Raymond-Hamet et Colas* **(M. krukovii** *A.C. Sm.***)** – xuxuá, chuchuhuasi, chuchuhuasha

Maytenus ilicifolia *(Schrader) Planch.* – espinheira santa, kangorosa

Maytenus laevis *Reissek* **(M. ebenifolia** *Reiss.***; M. jauaensis** *Steyerm.***)** – chuchuhuasi, chuchuhuasca, chuchuhuasha, chuchuguache, chuchuguaza, coemeni

Maytenus spp. are valued as treatments for rheumatism in the Amazon, particularly in Peru and Colombia. M. laevis is used by some Peruvian shamans as an ayahuasca additive, and is taken by Lamisto apprentice shamans a few weeks after taking ayahuasca [see **Banisteriopsis**]. It may also be taken under diet as a plant teacher and tonic medicine. Besides treating rheumatism, it offers protection against cold (Bear & Vasquez 2000; Luna 1984; McKenna et al. 1995; Schultes & Raffauf 1990). Extracts of the root bark have shown antitumour effects. The medicinal alcohol infusion of the bark is commonly referred to as 'chuchuhuasha' or similar names (González, J.G. et al. 1982). M. laevis is used medicinally by the Siona, particularly those who have become urbanised, where the bark is soaked in aguardienté overnight, and drunk as a painkiller for rheumatism and arthritis. Jungle Siona prefer to boil a 5cm trunk segment in 2 litres of water, reducing its quantity by half; a small cup of the decoction is drunk 3 times a day. It has the reputation of being a strong stimulant (Schultes & Raffauf 1990). As M. krukovii, M. chuchuhuasha is used in Brazil to treat skin cancer (Shirota et al. 1996). It has been suggested that M. krukovii, M. laevis and M. macrocarpa are the same species (Jones 1995), but I am seeking confirmation of this.

M. ilicifolia is used as an aphrodisiac in southern Brazil (Mors & Rizzini 1966). In Paraguay, its rhizome is decocted as an abortifacient, and to treat amenorrhoea, ulcers and cancer. The leaf is sometimes used to adulterate 'maté' [see **Ilex**] (Basualdo et al. 1995). In Argentina, it is used as an antiasthmatic, antiseptic, vulnerary and sialogogue [promotes salivation] (Zhu et al. 1998).

In TCM, the fruit, bark, and rhizome from M. buchananii, M. conterliflories, M. hookeri and/or M. serrata are now used [as 'mei deng mu'] in treating cancer. They must be used in small doses, due to toxic side effects such as diarrhoea, nausea, vomiting and liver toxicity (Huang 1993).

M. chuchuhuasha has yielded small amounts [<0.002%, w/w] of the triterpene dimers xuxuarine Eβ, isoxuxuarines Aα & Aβ, 7,8-dihydroxuxuarine Aα and 7,8-dihydroisoxuxuarine Aα (Shirota et al. 1997). As M. krukovii, it has been claimed to contain d-cathine [*norpseudoephedrine*] and d-*cathinone*, strong CNS-stimulants [see **Catha**] (Harborne & Baxter ed. 1993; Smith 1939), but I can find no primary reference for this, and the claim needs verification. Dried stem bark has also yielded 0.019% mayteine and 0.0015% 6-benzoyl-6-deacetylmayteine [sesquiterpene-pyridine alkaloids] (Sekar et al. 1995), as well as 0.05% of the triterpenes krukovines A-E (Shirota et al. 1996).

M. ilicifolia has yielded triterpenoids, triterpenoid dimers, oligo-nicotinated sesquiterpene polyesters and 3 glucosides [ilicifolinosides A-C] (Zhu et al. 1998).

M. laevis bark has been found to contain the phenoldienones tingenone and 22-OH-tingenone, as well as 4'-methyl-(-)-epigallocatechin and Ouratea-proanthocyanidins A & B (González, J.G. et al. 1982); bark also yielded sesquiterpene-pyridine alkaloids – ebenifoline E-1, euonine, euonymine, euojaponine, euojaponine I, laevisines A & B, mayteine and

wilforine (Piacente et al. 1999).

M. senegalensis has yielded triterpenes and sterols, and has shown antitumour activity in mice (Tin-Wa et al. 1971).

An unidentified Maytenus sp. from the Rio Ica in Brazil is used locally as a diuretic, and yielded 0.85% *caffeine* from its arils (Schultes & Raffauf 1990).

Maytenus chuchuhuasha is a glabrous tree to 28m tall; branches terete, slightly flattened when young, slender, soon ash-grey. Petioles rugose, narrowly winged or conspicuously grooved longitudinally, 6-9mm long; leaves coriaceous when dry, olive-green or dark brown, oblong-elliptic or obovate-elliptic, 9-14(-18)cm long, 3.5-5(-7)cm wide, base attenuate and in petiole decurrent, apex acuminate (acumine to 10mm long, appearing obtuse), margin mildly revolute and superne above crenate-serrate, midrib prominent on both sides, lateral nerves 7-9 paired, adscending, near margins anastomose, on upper side immersed and obscure, on under side slightly raised, minor veins obscure. Inflorescence axillary, glomerules 4-5mm diameter; flowers sessile to subsessile (pedicel c.0.5mm long), numerous (50 or more per inflorescence), bracts minute; calyx cupuliform, sepals deltoid, subacute, 0.8-1mm long, c.0.6mm wide, towards apex minutely glandulose-fimbriate; petals imbricate, oblong-deltoid, 0.8-1.2mm long, c.0.8mm wide, apex obtuse to rotundate; filaments minute, 0.2mm long, apex angustate; anthers deltoid-ovoid, c.0.5mm long and wide, base deeply cordate, apex minute mucronulate. Disc slightly fleshy, c.1.2mm diameter, margin undulate; ovary immersed in disc; style thick, c.0.4mm long, inconspicuously lobed. Fruit an oblong-obovoid coriaceous capsule, c.20mm long, 14mm wide, bivalved, pericarp 1-1.5mm thick.

Brazil [near mouth of Rio Embira, basin of Rio Jura, Amazonia; between Rio Madeira and Rio Capana].

Closely resembles M. laurina of the Rio Negro; differs in smooth upper leaf with immersed nerves, as M. laurina has nerves sharply impressed above (Smith 1939).

MELICOPE

(Rutaceae)

Melicope erythrococca *Benth.*
Melicope leptococca *(Baillon) Guillaumin* **(Evodia leptococca** *Baillon***)**

I have found no ethnobotanical uses for these plants; however, their chemistry is of interest.

M. erythrococca bark from Yarraman, Queensland [Australia], harvested in October, tested positive for alkaloids (Webb 1949). The bark has a 'tingling taste', and produced excitation in frogs, followed by paralysis of the spinal cord and death. "The active principle is apparently a protoplasmic poison, 'destroying every part of the animal economy'" (Hurst 1942). The plant also yields an essential oil containing *elemicin* (Shaw et al. comp. 1959).

M. fareana leaf and bark from Boonjie, Queensland [harv. Aug.] tested strongly positive for alkaloids (Webb 1949). The bark has yielded lupeol, the furoquinoline alkaloid acronycidine [4,5,7,8-tetramethoxyfuro[2,3-b]quinoline], and the acridines melicopine, melicopicine [1,2,3,4-tetramethoxy-10-methylacridone] and melicopidine [N-methyl-1,4-dimethoxy-2,3-methylenedioxy-9(10H)-acridone]; leaves have yielded these last 3 alkaloids, as well as the furoquinoline *skimmianine* (Shaw et al. comp. 1959).

M. leptococca aerial parts yielded 0.61% alkaloids [following figures as % of total alkaloids] — 35% *5-methoxy-DMT* [*5-MeO-DMT*], 5% *5-MeO-DMT* N-oxide, 4% 2-methyl-*pinoline*, 10% acronydine, 7% melicopicine, 3% melicopidine, 30% kokusaginine [see **Dutaillyea**], 1% acronycine [acronine; 3,12-dihydro-6-MeO-3,3,12-trimethyl-7H-pyrano[2,3-c]acridin-7-one], 2% acronycidine and 1% dimethylaminoacetyl-3-methoxy-5-indole [the ketone analogue of *5-MeO-DMT*] (Skaltsounis et al. 1983); the plant has also yielded acronidine (Buckingham et al. ed. 1994).

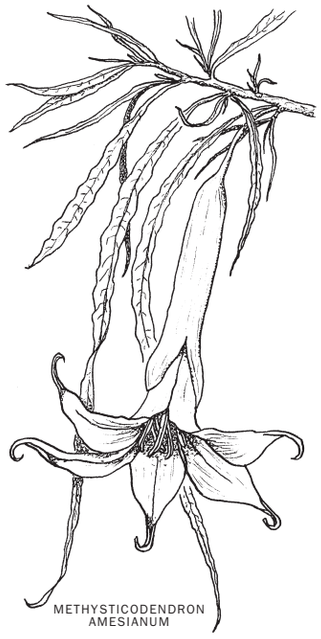
M. leratii aerial parts yielded 0.33% alkaloids, including *skimmianine*, melicopidine, xanthevodine and 1,2,3-trimethoxy-10-methylacridan-9-one (Ahond et al. 1978).

M. neurococca leaf and bark [harv. Nov.] from Pine Mt., Queensland [Australia] tested weakly positive for alkaloids (Webb 1949).

Melicope leptococca is a small bushy shrub growing at higher elevations of Mt Boulinda, New Caledonia (Shulgin & Shulgin 1997). I have not personally managed to obtain the source for its description, which was reported to be found in Bull. Mus. Hist. Nat. Paris 1920, xxvi. 175. However, an overseas friend who did locate this reference found that it did not contain any description, merely a note that Evodia leptococca had been re-named as M. leptococca; from what could be understood from this French article, the description of E. leptococca seemed to exist only in an unpublished manuscript.

METHYSTICODENDRON

(Solanaceae)



Methysticodendron amesianum *Schultes* **(Brugmansia amesianum** *(Schult.) D'Arcy***; Datura candida** *(Pers.) Saff.* **cv. 'culebra'** *Bristol***)** – culebra, culebra borrachero ['intoxicant of the snake'], metskwai borrachero ['intoxicant of the jaguar'], mits-kway borrachero, mutscuai borrachero, kin-de borrachero, goon'-ssi-an borrachero

This tree, closely related to **Brugmansia** spp. [generally considered a mutant **Brugmansia** cultivar], is occasionally used by Inga and Kamsá shamans of the Colombian Sibundoy as a hallucinogen. Its common names are indicative of its properties. It is considered very strong, stronger than **Brugmansia**, and is only taken in very difficult cases of divination. The effects may last 2-4 days, with much of that period spent in an apparent comatose state. In small doses, it is given to novice shamans to impart its teachings. For consumption, up to 6 of the leaves are collected within an hour of intended use, crushed, and infused in cold water for ½ hour. Just before consumption, the infusion is lightly heated [never boiled] and stirred, before being strained, and drunk over a 2-3 hour period. It is taken only on a waning moon phase. The plant is also used medicinally. Leaves and flowers are heated in water and applied externally to tumours and rheumatic swellings; a similar decoction may be used as a bath to treat persistent fever and chills (Bristol 1969; Davis 1996; Schultes 1955b; Schultes & Raffauf 1990; Uscategui 1959). Incidentally, Bristol (1969) doubted the shamanic use of M. amesianum, as he was unable to uncover any such use in the Sibundoy valley. In any case, Schultes (1955b) noted that only several shamans in each tribe know how to use the plant.

M. amesianum leaves and stems have yielded 0.3% alkaloids [leaves alone yielded 0.55%], consisting of *hyoscine* [80% of total alkaloids; 53-60% in leaves alone], norhyoscine, apohyoscine, *atropine*, noratropine, *hyoscyamine*, meteloidine and oscine (Bristol et al. 1969; Pachter & Hopkinson 1960).

Methysticodendron amesianum is a tree to 8m tall or more; leaves narrowly linear-ligulate, membranaceous, apex acuminate, base attenuate, margin undulate, 20-26 x 1.3-2cm, central nerve robust. Flowers 23-28cm long, apex in anthesis 10-13cm diam., usually solitary; calyx tubular, spathaceous, membranaceous; corolla very deeply lobose, divided to 3/5-4/5 of its length, lobes 5, apices long-acuminate, tube wholly enclosed within calyx; stamen filaments c.5cm long, 2mm diam. at base; anthers 2.7-3cm long, 3-4mm diam. Ovary subcylindric, 1.5cm long, 0.5cm diam., with 3 conduplicate carpels, the walls of which fuse c.1/3 of the way down to form a trilocular syncarp; ovules apical, ovule cavity somewhat open at apex, exposing the ovules; styles 3, free, concave, c.9cm x 2.5mm, with undivided stigmatic areas; stigma 2-lobed, 1-1.5cm, decurrent, papillose; appendages usually homologous with styles, but shorter, accompanied by 2 knob-shaped, clavate or subulate style-like projections. Fruits unarmed, smooth, indehiscent, fusiform, c.15cm long.

In cold, damp, high-altitude forests; Sibundoy Valley, Colombia (Schultes 1955b).

MICHELIA

(Magnoliaceae)

Michelia champaca *L.* **(M. blumei** *Steud.***; M. euonymoides** *Burm. f.***; M. pilifera** *Bakh. f.***; M. pubinervia** *Blume***; M. rufinervis** *Blume***; M. suaveolens** *Pers.***; M. tsiampacca** *Blume***; M. velutina** *Blume***; Magnolia champaca** *Baill. ex Pierre***; Ma. membranacea** *P. Parm.***; Sampacca suaveolens** *(Pers.) Kuntze***; S. velutina** *Kuntze***; Talauma villosa fo. celebica** *Miq.***)** – yellow champaca, true champaca, champa, champáka, sampáka, champákang-pulá

Michelia longifolia *Blume* **(M. x alba** *DC.***; Sampacca longifolia** *(Blume) Kuntze***)** – white champaca

Michelia montana *Blume* – chempaka

The dark brown wood of M. montana is lightweight and durable, and is thus used in construction of bridges and houses. Its aromatic bark is used in n. India as a bitter tonic for fevers. The related M. champaca is used for fevers in the same way; its leaves are also used as food for silkworms [see also **Morus**, *Endnotes*]. In Thailand its flowers are used as a perfume. In India, the flowers are used as a stimulant, tonic, purgative and carminative. Also in India, a water maceration of the leaves is used as an eye wash to clear the vision. When anointed with 'ghee' [clarified butter] and sprinkled with 'cumin' [Cuminum cyminum] seed powder, the leaves are applied to the head to relieve "puerperal mania, delirium and maniacal excitement". The flowers of the tree yield an essential oil known as 'champaca oil'. For this purpose, flowers must be processed quickly after harvesting, as they quickly lose their fragrance. The Himalayan M. excelsa and M. kisopa are said to have the same properties as M. champaca. M. fuscata [M. figo] from China is also used for the banana-scented essential oil [see **Musa**] in its flowers (Brooks 1911; Dutta et al. 1987; Nadkarni 1976; Usher 1974; West & Brown 1920).

M. alba has yielded the *phenethylamine* alkaloid salicifoline [see also **Magnolia**] (Smith 1977a).

M. champaca flowers have yielded c.0.2-0.37% essential oil, containing iso-*eugenol*, cineole, phenylethyl alcohol, benzyl alcohol, benzaldehyde, benzoic acid and acetic acid (Brooks 1911; West & Brown 1920).

M. longifolia flowers have yielded 0.0125% essential oil, containing *methyleugenol*, linalool and a methylethylacetic acid ester (Brooks 1911).

M. montana leaf essential oil [0.95% yield] contained mostly [75%] *safrole*; trunk bark essential oil [0.36% yield] contained mostly [76%] 'sarisan' [*asaricin*] (Dutta et al. 1987). Another analysis of leaf essential oil [plants from Assam, India] found 81.8% *asaricin* and 13% *safrole* (Van Genderen et al. 1999).

Michelia montana is a glabrous tree c.6-9m tall. Leaves thinly coriaceous, obovate, narrowed at both ends, dark green, 15.2-19cm long, 10.2cm wide, nerves 12 pairs; petioles 1.9cm long. Flowers white, fragrant, 3.8cm across, solitary in axillary or terminal peduncle 1.3cm long; sepals and petals 8, oblanceolate or lanceolate-acute, in 3 or more rows; stamens 18-24; pistils 3-4; carpophore stalked, carpels usually many, spirally arranged on an elongated axis, free; anthers introrse, long, narrow. Ovules 2 or more. Follicles woody, usually 1, subglobular pyriform, 7.6cm long, walls 1.3cm thick, in a lax or dense spike dehiscing dorsally; seeds 4-5.

In mountains, rare; Himalaya, Java (Ridley 1923).

Cultivate from seed or cuttings. Trees flower abundantly from the fourth year; collect flowers from mid-June to mid-October (Brooks 1911).

MIMOSA

(Leguminosae/Mimosaceae)

Mimosa acutistipula var. acutistipula *Benth.* – jurema preta ['black jurema']

Mimosa arenosa var. arenosa *(Willd.) Poiret* **(M. malacocentra** *(Mart.) Benth.***; M. xantholasia** *Benth.***; Acacia arenosa** *Willd.***; A. malacocentra** *Mart.***)** – jurema, jurema branca ['white jurema'], calumbi, calumbi branco, calumbi preto, calango cego, amorosa

Mimosa burgonia *Aubl.* – jurema branca, jurema marginada

Mimosa ophthalmocentra *Mart. ex Benth.* – jurema, jurema preta, jurema branca, jureminha, calumbi preto, calumbi vermello

Mimosa pigra *L.* **(M. asperata** *L.***; M. berlandieri** *A. Gray ex Torr.***; M. brasiliensis** *Niederl.***; M. canescens** *Willd.***; M. ciliata** *Willd.***; M. hispida** *Willd.***; M. pellita** *Humb. et Bonpl. ex Willd.***; M. polyacantha** *Willd.***)** – sensitive du Senegal, mimosa rebarbatif, sa she, gajanje

Mimosa polydactyla *Humb. et Bonpl. ex Willd.* **(M. hexaphylla** *Salzm. ex Benth.***)** – amor dormedo ['sleeping love'], vergonsosa

Mimosa pudica *L.* **(M. balansae** *Micheli***; M. hispidula** *Kunth***; M. tetrandra** *Humb. et Bonpl. ex Willd.***; M. unijuga** *Duchass. et Walp.***)** – common sensitive plant, dormideira ['soporific'], dormilona ['sleepy one'], espina dormilona, duermidillo ['little soporific'], jurema branca, muigin, guaring, sleeping grass, punyosisa, honte, morivini, daven kagat-kaget, dedinnaru, dorme dorme, huya-huya, malu-malu, hanxiou-cao, ajalikalika, shame bush, shame lady

Mimosa scabrella *Benth.* **(M. bracaatinga** *Höhne***)** – abaracaatinga, bracaatinga, paracaatinga

Mimosa somnians *Humb. et Bonpl. ex Willd.* **(M. acutiflora** *Benth.***; M. palpitans** *Humb. et Bonpl. ex Willd.***; M. podocarpa** *Benth.***; M. quadrijuga** *Salzm. ex Benth.***; M. somniculosa** *Kunth***; M. tobagensis** *Urb.***)** – dormideira, dormilona

Mimosa tenuiflora *(Willd.) Poir., non Benth.* **(M. cabrera** *Karsten***; M. hostilis** *(Martius) Benth.***; M. limana** *Rizzini***; M. maracasensis** *Harms***; M. nigra** *Huber nom. nud.***; Acacia hostilis** *Mart.***; A. tenuiflora** *Willd.***)** – jurema, jurema preta, cabrera, cuji cabrera, calumbi, carbonal, tepescohuite, urban ginseng

Mimosa verrucosa *Benth.* – jurema, jurema branca, jurema mansa ['gentle jurema'], jurema preta, caatinga

M. tenuiflora, and to a lesser degree M. verrucosa. were once used extensively in n.e. Brazil [by groups such as the Kariri, Tusha, Fulnio, Pankaruru, Acroa, Guege, Atanaye and Pimenteria] to prepare a ritual entheogenic drink known as 'vinho de jurema', or 'ajucá'. The spirit with which the drink brings the consumers into contact is also called Jurema. It is still prepared and consumed today, but existing only on a limited basis. The common use of M. verrucosa preparations have been observed to often be inactive as psychedelics, seemingly acting as placebos. Some groups, however, such as the Kariri-Shoko, do prepare a psychoactive drink from M. verrucosa, though they say it is 'gentle', and 'does not drive one crazy' like 'jurema preta', M. tenuiflora. Effects are said to be much more subtle than those of M. tenuiflora, and to manifest days later in dreams. Apparently, M. ophthalmocentra is also used as a jurema; it also has medicinal uses, as an antiseptic and antiinflammatory. The festival of the drink, attended by those entitled to do so, is usually held at night in the middle of the forest. The root of the tree is scraped clean and washed free of dirt, before being beaten to a pulp between two stones. The pulp is added to a vessel of water, in which it is hand-kneaded until the liquid turns red and frothy; the froth and the root pulp are strained out, and the drink is ready [others have said it is boiled for a long time in the water, though this is probably in error]. The leader of the ceremony lights a tubular pipe made from the root, and inhales the smoke to blow over the drink in the form of a cross. The vessel is placed on a leaf mat and all present sit around in a circle. A spiritual mood prevails as the drink is served to each person. Remaining liquid is poured into a special pit, and singing and music fill the air throughout, while jurema root pipes are passed around. The participants are filled with the spirit of Jurema, and receive glorious visions which strengthen their lives (Batista & De Almeida 1997; Da Mota 1997; De Lima 1946; Emboden 1979a; Lowie 1946; Ott 1993).

Several other Mimosa spp. are known as types of 'jurema' or 'jurema branca', and might be used as such, including M. arenosa var. arenosa, M. burgonia, and M. pudica; M. acutistipula var. acutistipula is also known as 'jurema preta' (Ott pers. comm.; Ott 1997/1998; Queiroz 2000). See also **Acacia**, **Pithecellobium**.

As 'tepescohuite', powdered bark of M. tenuiflora has been used in Mexico to treat burns and prevent inflammation. The same common name and medicinal application are referred to M. tenuefolia by Dominguez et al. (1989), which is probably in error. These authors also gave M. cabrera as a synonym, which is a known synonym for M. tenuiflora, as well as claiming the plant is in the subfamily Fabaceae, which it is not [as listed above, Mimosa spp. are placed in the Mimosaceae].

Mimosa spp. root paste was apparently popular with Latin American girls, smeared on the soles of the feet as an aphrodisiac (Rätsch 1992). The Tarahumara of n. Mexico use the crushed roots of M. dysocarpa ['karároa' or 'garáowa'] to stupefy fish (Pennington 1958).

M. pudica [whose leaves fold down when touched] is cultivated as a soporific in Veracruz, Mexico, and its roots are also used to regulate menstruation. In Panama, the Guaymi infuse the ground stem for arthritis; in Guatemala it is decocted to treat urinary infections. The Mayans of Belize use it as a soporific, as did the Aztecs, who used the root juice. In India, the root is considered aphrodisiac, and is used to treat epilepsy (Nadkarni 1976; Ott 1993). In Ecuador, the leaves are put into pillows to treat insomnia amongst the young and the elderly (Schultes & Raffauf 1990). The Chami say that if taken in strong doses, the plant can cause insanity (Duke & Vasquez 1994). In Senegal and Trinidad, a leaf or root infusion is taken as a calming, soporific drink. In Senegal, the root in decoction is given as a sexual stimulant to aged men (Burkill 1985-1997). In Vietnam, the herb is used as a hypnotic tranquilliser (Ott 1993), and a root decoction is used amongst the Hmong of the 'Golden Triangle' in Thailand to treat shock and fainting due to spirits (Anderson 1993). In TCM, the dried stem is decocted in doses of 5-7g as a tranquilliser to treat neurosis, 'trauma wounds' and haemoptysis [it should also be avoided by pregnant women] (Huang 1993). In Nepal, M. rubicaulis flowers ['bokshi ghans' ('witch's flowers')] are an ingredient [along with three types of chilli - see **Capsicum**] in one recipe for 'bokshi dhup', an incense used to protect against the evil influence of witches (Müller-Ebeling et al. 2002).

The foliage and twigs [or whole plant] of M. pudica have been both smoked and infused as an obscure psychotropic drug by experimenters in the US, reportedly producing distortions of spatial orientation, feelings of expanding and contracting gravity, and mild visual effects (pers. comm.). After personal experimentation, I can confirm the plant is psychoactive, but these reports seem to be exaggerated. It should be noted that overdose of the root-extract is purgative, and may even cause coma and death (Burkill 1985-1997).

M. somnians ['dormilona'] may be used as a soporific in Panama. In El Salvador, guerillas smoke a Mimosa sp. they call 'dormilona' when they have no **Cannabis**, and a tea of dried leaves is said to have the strongest effects (Ott 1993). In parts of the Amazon, M. polydactyla flowers are infused as a nervine sedative (Duke & Vasquez 1994). In Gabon, the Bwiti administer eye-drops of a root-extract of M. pigra and other plants to initiates, so that they may 'see that which is hidden' [see **Tabernanthe**]. In Tanganyika, a leaf infusion is taken to make one invisible for war; it is also given to chickens, so that they may become invisible to hawks (Burkill 1985-1997). The root is used as an aphrodisiac, but it has a calming effect on some people (Watt & Breyer-Brandwijk 1962).

Due to its rich *DMT*-content [see below], the root bark of M. tenuiflora has, in recent years, been widely used in preparation of ayahuasca analogues, with suggested doses ranging from 8-15g root bark, in addition to MAOI [see *Methods of Ingestion*]. Addition of honey to such brews is recommended, to counteract the astringency of the bark decoction. M. tenuiflora bark used in ayahuasca analogues is often reported to cause much more nausea and vomiting than other admixtures, such as **Psychotria** or **Diplopterys** (Trout ed. 1998; pers. comms.).

It has recently been found that 25g of such root bark is active alone for some people, kneaded in a cold-water infusion, supporting the original ethnobotanical reports of jurema use. Many people have assumed that the use of jurema was once accompanied by some form of plant-based MAOI [and sometimes it is - see **Passiflora**], and further assumed that the knowledge of this admixture had been lost, the jurema-drinkers continuing the practice in a symbolic imitation of past rites. When used in this way, the pounded or shredded root bark is prepared simply by kneading in cold, neutral water and leaving to soak twice, for 30 minutes each time, before pressing out and consuming the liquid. The psychoactivity of this plant, taken alone, is thought to be due to the additional presence of *DMT*-conjugates which are not substrates to MAO, surviving into the brain, where they are rendered active (Ott pers. comm.; Ott 1997/1998). The eventual isolation of one such new alkaloid is discussed below. It should be mentioned that some others trying to self-duplicate this example have perceived no psychoactivity with the dose suggested, though definite somatic sensations from the *DMT* in the body were felt. Other have had definite mild *DMT*-like central and somatic effects from 35-45g of root bark, with effects lasting from 20 minutes to 2 hours (pers. comms.).

Besides indole alkaloids, some Mimosa spp. contain the water-soluble amino acid mimosine [leucinine, leucenol, α-amino-3-OH-1(4H)-pyridinepropanoic acid] (Buckingham et al. ed. 1994; Budavari et al. ed. 1989), which is toxic to animals. It causes hair-loss in horses, sheep and pigs, but ruminants are able to detoxify it and remain unaffected. Other effects include weight loss, malaise, cataracts and infertility. It is teratogenic in rats, and inhibits DNA synthesis (Harborne & Baxter ed. 1993; Keeler 1975). Caution should obviously be exercised when consuming crude preparations, due to the unknown human toxicity of mimosine.

M. ophthalmocentra roots yielded 3% tertiary alkaloids; 1.6% *DMT*, 0.0012% *N-methyltryptamine* [NMT] and 0.0065% *hordenine* were isolated. The various fractions of the extract were tested on rats [i.p.] at each stage of the extraction process; only fractions containing *DMT* or *NMT* were shown to cause serotonergic effects thought to reflect "hallucinogenic activity". These extracts appear to act at 5-HT2 receptors (Batista et al. 1999). Stem bark also yielded the same alkaloids (Batista & De Almeida 1997).

M. pigra leaf has yielded mimosine; some tests of leaves have been negative for the presence of alkaloids (Burkill 1985-1997; Watt & Breyer-Brandwijk 1962); stem bark has yielded triterpenoid saponins (Englert et al. 1995); seeds were shown to contain 4-OH-pipecolic acid and willardiin [willardiine] (Krauss & Reinbothe 1973).

M. polydactyla twigs, leaves and pods were independently analysed by TLC, and tentatively observed to contain small amounts of *DMT*, *NMT* and *5-methoxy-DMT* [5-MeO-DMT] (Trout ed. 1998).

M. pudica stems contain the amino acid mimosine and the glycoside mimoside; the pulvinus contains crocetin [see **Crocus**] (International...1994; Tiwari & Spenser 1965); and the primary pulvinus and petiole contain *norepinephrine* [0.00006-0.00035% in 2-yr old plants] (Applewhite 1973). Independent TLC tests have shown the possible presence of *DMT* in the seeds, and also in roots and leaves of 2nd year plants; possible *5-MeO-DMT* was also found in aerial parts and roots of seedlings and 15 month old plants [harv. Nov.], with higher amounts in the roots (Trout ed. 1997d). The water-extract of the roots has been shown to inhibit the lethality, enzyme activity, and muscle toxicity of **Naja** kaouthia venom (Mahanta & Mukherjee 2001), and the hyaluronidase and protease activities of **Naja** naja, Echis carinatus and Vipera russelii venoms (Girish et al. 2004). Seeds of M. pudica var. hispida were shown to contain small amounts of pipecolic acid (Krauss & Reinbothe 1973).

M. scabrella bark has yielded less than 0.0357% *DMT*, as well as *NMT*, *tryptamine* and 2-methyl-THβC (De Moraes et al. 1990). It is interesting to note that this tropical/subtropical species has been found to grow well in Newcastle-upon-Tyne, n. England (Trout ed. 1998).

M. somnians [whole plant] yielded 0.026% *tryptamine* and 0.029% *NMT* [harv. summer, Panama] (Gupta et al. 1979), as well as *DMT*, *bufotenine*, *5-MeO-DMT* and 5-MeO-*NMT* (Shulgin & Shulgin 1997), though these latter claims might be in error (Trout ed. 1997d).

M. tenuiflora root has yielded 0.57% *DMT* [though this may have actually used the root bark]. An earlier study found 0.51% 'nigerine' in root bark (Pachter et al. 1959), which is thought to have been an impure mixture of *DMT*, and possibly *DMT* N-oxide and other compounds. Another early study found 0.98% 'nigerine', in root bark from the same location [Arcoverde, Pernambuco (Brazil)]. In unpublished research, one sample of Brazilian root bark from Alhandra, Paraíba was shown to contain c.11% *DMT*! The jurema beverage made from this material contained 7.46mg/ml *DMT*, though the doses used traditionally are not known. Bioassays [in ayahuasca analogues] of some commercially available Mexican M. tenuiflora root bark indicates approximate concentrations of 1% *DMT* (Ott 1997/1998). Similar yields have been obtained by independent psychonauts, through alkaloid extraction (pers. comms.). A more recent analysis of micro-propagated trees found [as percentages from Jan./Jun. harvests] stem bark to contain *DMT* [0.35/0.11], *tryptamine* [0.0022/0.0071] and *tryptophan* [0.0021/0]; leaves to contain *DMT* [0.01/0.09], *serotonin* [0.009/0], *tryptamine* [0.0037/0.0074] and *tryptophan* [0.00215/0]; and flowers to contain *DMT* [0.03/0], *tryptamine* [0.0075/0] and *tryptophan* [0.0007/0] (Nicasio et al. 2005). Independent TLC analysis of commercially-obtained root bark [originating from Mexico] found 4 strong bands corresponding to *DMT*, possibly *N-methyltryptamine*, and two other unidentified compounds (Trout ed. 1997-1998). Stem bark has yielded 0.03% *DMT* and 0.001% *serotonin*, though the sample had been subjected to high temperatures before the extraction process (Meckes-Lozoya et al. 1990); also found are terpenoids [mimonosides A-C] which have been shown to activate and prolong cell multiplication for about 10 days (Bruneton 1995; Jiang et al. 1991). Stem bark from Oaxaca [Mexico] recently yielded 0.11% [w/w] yuremamine, an unstable alkaloid with an indole nucleus; it is thought that yuremamine may be immune to metabolism by MAO, and might even be an MAOI, contributing to the activity of jurema beverages (Vespäläinen et al. 2005); others believe it may have *DMT*-like psychoactivity in its own right (pers. comms.). Callus cultures from the cotyledons and hypocotyl have yielded 0.037-0.069% *DMT* (Villareal et al. 1993). As M. tenuefolia [probably a confusion with M. tenuiflora – see above], small branches have yielded 2 chalcones, kukulkanins A [0.014%] & B [0.028%] (Dominguez et al. 1989).

M. verrucosa has been claimed to contain *DMT* (Ott 1993; Smith 1977b), and this may well be the case, but chemical analyses seem to be lacking.

Mimosa tenuiflora is an often prickly shrub or tree 2-5m tall with stiff, knotty, fuscous-livid or blackish branches, erratically armed with thorns 2-10mm from a swollen pediment; branchlets and foliage puberulent, +- resinous or viscid with soft hairs 0.1-0.3mm and minute glands; stipules deltate to triangular-acuminate, (0.5-)1-2.5mm, deciduous. Leaf stalks (2-)2.5-6.5(-9.5)cm, the petiole incl. livid pulvinus 7-14mm, the longer interpinnal segments (3-)4-9(-11)mm, the ventral groove interrupted between pinnae by a spicule 0.3-1mm; pinnae usually 4-7(-11), decrescent proximally, the rachis of longer ones (2-)2.5-5(-5.5)cm, the longer interfoliar segments 1-2.2(-2.5)mm; leaflets glabrous or finely puberulent, often minutely ciliolate, dorsally sprinkled with glands, leaflets of longer pinnae (15-)17-33(-40)-jugate, decrescent only near ends of rachis, linear-oblong, obtuse or minutely apiculate, the longer ones (3.5-)4-8 x 1-1.6mm, faintly 2-nerved dorsally, upper face veinless. Flower spikes from axils of fully expanded or already fallen leaves, solitary or sometimes geminate, subsessile, appearing as dense cylindric catkins c.5-10 x 2-3mm, axis becoming 4-10cm, loosely spicate; bracts cuneate-spatulate, 0.6-1mm, apex dilated and hooded, dorsally puberulent; flower buds oblong-obovoid, minutely glandular-papillate distally; flowers 4-merous, 8-androus, some often staminate; calyx turbinate-campanulate, 0.75-1mm, 4-angled by prominent ribs leading to the very short, cucullately incurved, dorsally puberulent lobes; corolla turbinate, 2.1-3.1mm, whitish or greenish-white, lobes 0.7-1.6mm, ovate, incurved, apex callous; filaments white, free, longer ones exserted, 3-4mm. Ovary grey-pilosulous laterally and glandular-verruculose. Pods narrowly oblong or oblong-elliptic, when well-fertilised 25-50 x 6-8.5mm, 4-6 seeded, body cuneately contracted at base to a slender stipe 2-4mm long, the shallowly undulate replum 0.3-0.5mm wide, valves viscid with glands, when ripe breaking into articles c.6-8mm long. Seeds roughly obovate-subcordate, 4-4.5 x 3.3mm, dull brown.

In brush-woodland, sometimes sandstone outcrops, sometimes forming weedy thickets in pastures along highways; usually up to 500m, but has been found up to 900m; n.e. Brazil [lat. 4-15°S], Venezuela, Guajira

Peninsula of n.e. Colombia, El Salvador, Honduras, lowlands of Oaxaca and Chiapas [Mexico] (Barneby 1991).

MIRABILIS

(Nyctaginaceae)

Mirabilis jalapa *L.* **(Nyctago jalapa** *(L.) DC.***)** – marvel of Peru

Mirabilis multiflora *(Torr.) A. Gray* **(Oxybaphus multiflorus** *Torr.***; Quamoclidion multiflora** *(Torr.) Torr. ex A. Gray***)** – desert 4-o'clock, Colorado 4-o'clock, wild south-western 4-o'clock, so'ksi, so'kya, maravilla, tsédédéèh

Mirabilis nyctaginea *(Michx.) MacMill.* **(Allionia nyctaginea** *Michx.***; Oxybaphus nyctagineus** *(Michx.) Sweet***)** – pretty by night

M. multiflora is used by the Hopi of N. America, whose shamans chew the root to induce visions, and help expel evil spirits from a patient. In smaller doses, it is chewed to treat stomach ailments. The Navajo smoke it with other herbs which make up the 'coyote chant' mixture. The Zuni powder the root and bake it into bread as an anorexic. It has the potential to be dangerous with careless use, and its use as a shamanic plant is often kept a secret to outsiders (Bluefeather pers. comm. 1996; Emboden 1979a; Ott 1993; Winter 1998).

The related M. jalapa is a very common garden plant, the root being a strong purgative and diuretic. It is said to have aphrodisiac properties, also treating urinary infection, scabies, eczema, inflammation, poor circulation and tonsillitis. At night, the flower scent is said to be stupefying. A leaf poultice may be applied to abscesses, and the leaves are eaten as a vegetable in Nepal. In China and Japan, women use the powdered seed as a cosmetic (Bremness 1994; Watt & Breyer-Brandwijk 1962). Yoruba men use the leaves to increase their virility (Verger 1995). The Hmong of n. Thailand use its roots as a stimulant, tonic, aphrodisiac, diuretic and post-partum treatment (Anderson 1993). M. jalapa root and seeds have caused poisoning in children, the symptoms consisting of acute stomach pain, vomiting and diarrhoea (Hamel & Chiltoskey 1975; Watt & Breyer-Brandwijk 1962).

The Cherokee use M. nyctaginea as a fly poison, and a poultice for boils (Hamel & Chiltoskey 1975). An unidentified Mirabilis sp. from South America bears the common name 'huillko', possibly derived from 'huillca' or 'villca', names applied to **Anadenanthera** spp. (Trout ed. 1998).

A dose of 28-57g [c.1-2 ounces] M. multiflora root [dry] is capable of inducing a state of 'gaeity and hyperactivity' lasting 30-60 minutes, followed by a period of 'befuddlement' (Ott 1993). Another user of the plant reported that at this dose "Its effects are more of a 'happy-go-lucky' type of 'feel-good' inebriant, than a profound psychoptic like *mescaline* or LSD[...]30 to 90 minutes after ingesting, one experiences merriment, light heartedness, and a tendency to laugh or giggle[...]after a couple of hours these effects are followed by muscular lethargy, slurred speech, blurred vision, and eventually it aids in restful sleep." One of his friends who tried the same dose vomited after 20 minutes, and did not experience any effects. The fresh root has a slightly sweet, peppery taste, and numbs the mouth when chewed (Hambly 2000).

M. himalaica roots have yielded daucosterol, N-pentacosanosyl-β-D-glucopyranosyl-(1-1')-phytosphingosine, N-hexacosanosyl-β-D-glucopyranosyl-(1-1')-phytosphingosine, syringaresinol-4'-O-β-D-monoglucoside, 2,3-dihydroxypropyl-(Z,Z)-9,12-octadecadienate, β-sitosterol, and oleanolic acid (Zhang et al. 1997).

M. jalapa has yielded trigonelline, indicaxanthin, miraxanthins I-IV, oxymethylanthraquinone and a resin (Buckingham et al. ed. 1994; Schermerhorn et al. ed. 1957-1974; Watt & Breyer-Brandwijk 1962).

The chemical contents of M. multiflora and M. nyctaginea appear to be unknown.

Mirabilis multiflora is a perennial herb from a long, pithy root 30-60cm long; stems erect to spreading or decumbent, 30-60cm long, forming clumps to 1m diam., usually stout, densely leafy, glaucous, pubescent, often viscid to glabrate, branches ascending. Leaves opposite, 3-7.5cm x 15-75mm, broadly ovate to reniform-orbicular or ovate-oblong, cordate or rounded at base, acute to rounded and apiculate at apex, thick and succulent, glabrous to pubescent, often glandular; petioles slender or stout, c.½ as long as leaf blade or shorter. Peduncles slender or stout, 0.5-6cm long; inflorescences solitary in axils and cymose at ends of branches, leaves of inflorescence reduced; involucres 15-35mm long, campanulate, usually 6-8 flowered, glabrous to glandular-puberulent or short-villous and viscid, green or tinged red; involucral lobes 5, equalling or shorter than tube, ovate-orbicular to triangular, rounded and apiculate to very acute; perianth 2-6cm long, trumpet-shaped, rose-coloured to violet or purplish-red, shallowly 5-lobed, glabrous or glandular-puberulent outside, the tube 4-7mm thick, expanding into a shallowly-lobed limb 2-3cm across; stamens 5, equalling perianth or slightly exserted; filaments filiform, incurved, united into a fleshy cup at base; anthers dorsifixed near base, didymous, opening by lateral slits. Ovary included in perianth-tube, 1-celled, membranous. Anthocarp 6-10mm long, conspicuously 5-angled or 5-ribbed, oval, obtuse at each end, smooth or slightly furrowed at base, dark brown to nearly black, glabrous; seed filling the pericarp to which the testa adheres. Fl. spring-autumn.

Dry slopes and plains, gypseous hills, on granite, rocky and sandy soils, limestone areas; from Colorado and s. Utah, south to Texas, Arizona, New Mexico and Mexico (Correll & Johnston 1970).

Sow seeds where they are to grow, spaced at least 35cm apart; can take several weeks to sprout. Prefers loose, dry, sandy desert-type soil, dug very deep to allow large root production. In colder climates, dig roots up and store them in winter. Harvest roots in autumn; dig up carefully, as they break easily, and can be quite large. Very drought- and cold-hardy when established. Can remain dormant for long periods (Grubber 1973; Hambly 2000). These plants have great weedy potential once established due to the difficulty in removing them permanently, as their roots may divide underground and regenerate from small pieces (pers. comms.).

MITCHELLA

(Rubiaceae)

Mitchella repens *L.* – partridge berry, checkerberry, deerberry, oneberry, squaw vine, hive vine, winter clover

The Menomini of N. America commonly use M. repens in the form of a berry or leaf infusion, to treat insomnia. It reputedly acts as a strong CNS-depressant and hypnotic (Emboden 1979a). The Cherokee use it as a diuretic and diaphoretic, as well as to relieve period pain, facilitate childbirth, and treat hives, dropsy, diarrhoea and uterine disorders. The berries have also been eaten as food (Hamel & Chiltoskey 1975), and may be used to treat dysentery (Hutchens 1973) and diarrhoea. A salve made from the plant has been useful as an application to sore nipples. The whole plant also has astringent and uterotonic properties (Felter & Lloyd 1898).

M. repens has been poorly studied chemically; the herb has been shown to contain saponins, and no observable essential oil (Felter & Lloyd 1898).

Mitchella repens is a creeping evergreen herb; stems rooting at the nodes, 10-30cm long, forming mats. Leaves evergreen, petioled, round-ovate, 1-2cm long. Flowers mostly terminal, paired, their hypanthia united, the common peduncle shorter than the subtending leaves; corolla funnel-form, white, 10-14mm long, with an elongate tube and (3-)4(-6) short spreading or recurved lobes, villous on inner face; stamens usually as many as corolla lobes; anthers 4, narrowly oblong, 2-celled, dehiscing longitudinally. Ovary 4-celled, with a single ovule in each cell; stigmas 4, slender. Fruit a twin berry, scarlet, composed of the ripened hypanthia and ovaries of the two flowers, 5-8mm diam., crowned with the short sepals, persistent through the winter, edible but insipid; 8-seeded. Fl. May-Jul.

Common in dry or moist woods; Nova Scotia to Ontario and Minnesota, south to Florida and Texas.

Forms with completely confluent corollas and white berries are M. repens forma leucocarpa (Gleason 1952).

MITRAGYNA

(Rubiaceae)

Mitragyna africana *Korth.*

Mitragyna ciliata *Aubrév. et Pellegr.* **(Hallea ledermannii** *(K. Krause) Verdc.***)** – poplar, abura, bahia

Mitragyna inermis *(Willd.) O. Kuntze* **(M. africana** *(Willd.) O. Kuntze, non. Korth.?***; Uncaria inermis** *Willd.***)** – false abura, pied d'éléphant, tsina ['cow tree'], dumo, koli

Mitragyna parvifolia *(Roxb.) Korth.* **(Nauclea parvifolia** *Roxb.***)**

Mitragyna speciosa *Korth.* – kratom, gratom, kutum, mambog, biak

Mitragyna stipulosa *(DC.) O. Kuntze* **(Hallea stipulosa** *(DC.) Leroy***; Nauclea stipulosa** *DC.***)** – African linden, false opepe [opepe = Nauclea diderrichii – see *Endnotes*], abura, bahia, uwem, subaha

Mitragyna spp.

The leaves of M. speciosa ['kratom'] are used as an opium substitute [see **Papaver**] in parts of s.e. Asia, particularly Siam, Thailand, Malaysia, Burma and Assam [India]. The leaves may be chewed fresh, smoked when dried, made into a tea [using up to c.9g leaf], or processed into a thick syrup called 'mambog' [used in a dose of c.0.4g], which may be smoked or otherwise consumed. By any route, its use is considered to be habit-forming. Sometimes, leaves are added to quids of 'betel nut' [see **Areca**] for chewing, to enhance the effect. Mambog may also be mixed with the powdered leaf of Licuala paludosa ['swamp fan palm'], and smoked in bamboo pipes. Kratom has also been used as a stimulant to reduce fatigue and appetite. It has been used in Thai folk medicine as a stimulant and analgesic, and to treat diarrhoea, fever, wounds [as a poultice], and opiate withdrawal, the latter in combination with M. parvifolia leaves (Emboden

1979a; Jansen & Prast 1988; Macko et al. 1972; Perry & Metzger 1980; Rätsch 1992, 1998; Schultes 1966; Tyler 1966). Kratom is highly illegal in any form today in Thailand; possession of the drug can lead one to a death sentence (pers. comms.). In Indo-China, M. parvifolia leaves are used as an appetite-stimulant (Perry & Metzger 1980).

In Mali, the Bambara of the Dyidé religion once used a leaf infusion of M. africana as a possibly entheogenic sacrament and initiatory agent. The practice was suppressed in the 1940's, but may remain 'undergound' (De Smet 1998; Trout & Friends 1999, citing Imperato, P.J. 1977. African Folk Medicine [York Press, Baltimore]). In Senegal, twigs, bark, and roots of M. inermis are decocted [the liquid being drunk as well as bathed in] to treat mental disturbances. Tandanké hunters clean their guns with a leaf-macerate as a magical act to help guide them to a deer suitable for killing. In Congo, a bark infusion of M. stipulosa is given to treat insanity, and in Ghana and Gabon, it treats sterility. In Ivory Coast, it is used to relieve stiffness, stomach-ache, poor eyesight, and to ease childbirth. The Yoruba believe the plant has powers of protection, and pray to it before a journey. In Liberia and Nigeria, leaves of M. stipulosa and M. ciliata are used as wrappers for 'kola nuts' [see **Cola**]. Several Mitragyna spp. are used in construction for their quality wood, such as M. macrophylla ['West African mahogany'] and M. stipulosa ['African linden' (see **Tilia**)] from Sierra Leone; the roots of the former treat stomach complaints, and the leaves of the latter treat coughs and fever (Burkill 1985-1997; Usher 1974).

The effect of M. speciosa has been described as being like "chewing coca [see **Erythroxylum**] and smoking opium simultaneously" (Jansen & Prast 1988), or even as "a pleasant reverie comparable to[...]**Psilocybe** or a small dose of LSD" (Emboden 1979a). These claims are not particularly accurate, however, despite their frequent repetition. Stimulant effects are observed with low doses of kratom, resembling the stimulation from *yohimbine* or *ibogaine* [low doses of the latter!], whilst higher doses reveal opium-like effects (Torsten pers. comm. 2001). Acute overdose can cause vomiting, vertigo, stupor, numbness and muscle-twitches. Extended, excessive use is said to result in emaciation, dark lips, dry skin, and constipation, as well as some of the above symptoms (Emboden 1979a; Jansen & Prast 1988; Rätsch 1992; Tyler 1966); some of these effects are perhaps more likely due to the lifestyle of a habitual drug-user in poverty, rather than entirely the effects of the plant.

Several leaves or more may be smoked or chewed, with effects being felt by 5-10 minutes (Jansen & Prast 1988). The effects have been described as emotionally blunting, inducing indifference. I found the leaves [from a small plant, c.2 years old, cultivated in Melbourne, Australia], smoked through a water pipe, to have pleasant effects similar to those induced by smoking **Vinca** major leaves (pers. obs.). Some people report very mild 'psychedelic' effects. Cessation of heavy, regular use gives rise to a withdrawal syndrome with symptoms including severe mood swings, jerky movement, runny nose and body aches (Jansen & Prast 1988). One psychonaut, who chewed kratom daily for 6 months, reported withdrawal effects that were much milder than opiate-withdrawal. He also did not agree with previous reports that the herb is highly addictive; he reported that it was not "any more habit-forming than *caffeine* or commonly prescribed SSRI anti-depressants". A synergy with **Cannabis** was noted, but he did not feel kratom was psychedelic, although causing "some level of closed-eye visuals". In lower doses [2-3 leaves; 1-1.5g] anxiolytic, anti-depressant, analgesic, and mild stimulant effects were noted; the stimulant effect was unlike that from other stimulants, and was described as more of a "mental clarifier". Higher doses [>3g] caused mild agitation, an itchy nose, constipation and *codeine*-like effects, sometimes with nausea and vomiting. Contrary to earlier reports, this psychonaut refuted any similarity to coca other than a numbing of the mouth. The leaf is effective either fresh or dried, though in the latter form it is more often made into a tea, which is not subjectively as strong as the chewed leaf. Lastly, this psychonaut was told by several kratom-users that the effects could be stopped within 5 minutes, by drinking lemon [see **Citrus**] or tamarind juice, though sugar would make the effects more severe (Wogg 2000).

Mitragyna spp. contain a variety of *mitragynine*- and *mitraphylline*-type alkaloids [indoles and oxindoles, respectively] with CNS-depressant and hypnotic-tranquillising effects, as well as other related indoles. M. speciosa is the only species known to contain *mitragynine*, believed to be the most important psychoactive alkaloid in Mitragyna spp., the others exerting only weak or no CNS effects.

The leaf of M. speciosa has a different action to pure *mitragynine*, and the other alkaloids clearly contribute in synergy to produce the full effects. In early experiments in which *mitragynine* was given to five men, it was found that the leaves were more effective than their equivalent *mitragynine*-content alone (Jansen & Prast 1988; Wogg 2000).

M. ciliata has yielded rhynchophylline, isorhynchophylline [see **Uncaria**], rhynchociline, ciliaphylline, rotundifoline and isorotundifoline (Shellard & Alam 1968).

M. inermis leaves have yielded mitraciliatine, speciogynine, rotundifoline, isorotundifoline, rhynchophylline, isorhynchophylline, speciophylline and uncarine F; stem bark and root bark yielded the same compounds, with the exclusion of mitraciliatine and speciogynine (Shellard 1983). Plants from Ghana yielded rhynchociline, rhynchophylline, isorhynchophylline, rotundifoline and isorotundifoline (Shellard & Alam 1968).

M. parvifolia from varying locations in s.e. Asia has yielded rhynchophylline, isorhynchophylline, rotundifoline, isorotundifoline, pteropodine, isopteropodine, speciophylline, *mitraphylline*, isomitraphylline and uncarine F (Shellard & Alam 1968).

M. speciosa leaves have yielded at least 22 indole and oxindole alkaloids; young, large leaves contain highest levels of alkaloids [0.46-0.5%], of which 66% may be *mitragynine* and 7.5% speciofoline, as well as [with values as % of whole leaf] *mitraphylline* [0.046%], isomitraphylline [0.0034%], 3-dehydromitragynine [0.0036% w/w], speciophylline [0.00052%], speciogynine [0.0061%], speciociliatine [0.00157%], mitraciliatine [0.0032%], *ajmalicine* [0.0019%], corynantheidine [0.0037%], paynantheine [0.0035% dry, to 0.005% w/w] and 7-α-OH-7H-*mitragynine*; leaves also contain (-)-epicatechin. Some trees do not yield *mitraphylline*-type alkaloids. Bark has yielded 0.26% alkaloids (Beckett et al. 1965, 1966a, 1966b; Hartley et al. 1973; Henry 1939; Houghton & Said 1986; Ponglux et al. 1994). Leaves of young trees yielded predominantly isocorynantheidine, isopaynantheine, mitraciliatine and speciogynine (Shellard et al. 1979). The tree has also yielded the alkaloids specionoxeine and isospecionoxeine (Saxton 1973).

M. stipulosa leaves have yielded *mitraphylline*, rhynchophylline, isorhynchophylline, rotundifoline, isorotundifoline, hirsutine, and traces of corynoxeine and isocorynoxeine (Shellard 1983; Shellard & Alam 1968); the plant has also reportedly yielded *yohimbine* (Rätsch 1998).

Alkaloidal yield and composition of Mitragyna spp. may vary at different times of year, and with plants grown in different habitats (Shellard & Alam 1968).

Mitragyna speciosa is a large tree 12-15m tall, trunk 60-90cm thick; young stems or twigs rectangular in internodal cross-section, in section 1-3 x 2-5mm, the shorter sides deeply grooved, the longer sides flat or slightly concave, all covered with thick dark brown cork bearing many oval or rounded lenticels. Young stems each bear 10-12 leaves in opposite, decussate pairs; leaves simple, membranous, ovate, slightly obovate, ovate-lanceolate or oblong, margin entire, apex acuminate, base obtuse, rounded, truncate or slightly cordate, glabrous on upper side, 10-17 x 5-10cm, distinct pinnate venation, most prominent on underside, 10-16 pairs of nerves, emerging from midrib acutely at 55-70°, angle decreasing near apex, they continue +- straight until nearing the margin, where they curve upwards and run parallel to the margin, fine reticulate venation between nerves, roughly parallel to each other, midrib and nerves pale brown to reddish-brown, elevated and slightly pubescent beneath, mostly where veins and nerves meet; petioles 3-5cm x 1.5mm, cylindrical, flattened or grooved on upper side, dull and rough, sometimes finely striated; 2 stipules subtending each pair of leaves, attached just above petioles, at right-angles to leaves, one slightly larger than the other (before young shoots emerge the two are closely adpressed and the margin of the larger stipule folds over that of the smaller one), oblong-lanceolate, to 5cm long, 2.5cm wide, yellowish-brown to reddish-brown when dried, with c.9 parallel ribs, glabrous, with 2-3 rows of elongated brown protuberances at base of upper surface, which secrete a sticky transparent substance when young. Flowers sessile, in globose, solitary or panicled heads c.30mm diam. mixed with spathulate, claviform paleaceous bracts (c.40 surrounding each floret); heads 3, one very shortly peduncled between two on the ends of long branches c.5cm long, 2.5cm thick in flower, deep yellow; peduncle with 2 petioled leafy bracts near tip; receptacle spherical, c.5mm diam., golden-brownish, clothed in long hairs; calyx conoid, gamosepalous, 5 sepals united more than ¾ of length, lobes and basal part golden, central part pale, lobe margins golden-brownish, sepals glabrous, oblong, rounded at lobes, c.2mm long, plano-convex, with prominent midribs, margin lobes ciliate; corolla 9-10mm long, gamopetalous, funnel-shaped, tube long and c.1mm diam., a ring of hairs in mouth, 5 petals joined more than ½ their length, +- linear, but widening towards lobes, with prominent midribs, golden to golden-brownish, lobes c. 4 x 1mm, tapering to a blunt point and thickened at tip, at right angles to tube, inner surface of corolla with abundant pale golden trichomes; stamens 5, c.3mm long, epipetalous, with long trichomes, alternating with corolla lobes, inserted near mouth of tube; anthers free, lanceolate, cordate, 2-lobed, colourless or pale grey, except for central golden region where filament joins the connective, c.1.8mm long, tapering to blunt point at base, lobes dehiscing lengthwise; filament dorsifixed, versatile, joined to anthers c.1/3 its length from base. Ovary c.1.5mm long, 1mm diam. at top, inferior, 2-celled, with ridges over the vascular bundles, +- angular in outline; ovules numerous, minute, pale golden, attached to axile placenta in overlapping patterns; style simple, slender, solid, cylindrical, widening slightly towards base, c.15mm long, extending c.4.5mm beyond corolla, golden, paler near base; stigma conical, apex blunt and rounded, fleshy, dark brown, c.1.5mm long, with c.10 flat, equal sides on surface, bases of which form slightly rounded lobes. Fruit head dark brown, globose, c.35mm diam., with c.90 fruits; fruits slightly flattened, ellipsoidal capsules, c.10mm long, 4mm wide at middle, topped with disc-like structure with a hard brown rim (remnant of calyx), sunken in centre, upper half of fruit with 10 prominent ridges, base surrounded by overlapping bracte-

oles with long basal hairs (bracteoles fall off at dehiscence), fruit bilocular, dehiscing longitudinally; seeds numerous, small, winged, fusiform, golden, central region darker than wings, attached to dark brown, striated placenta in overlapping pattern.

In swampy ground, open country, apparently rare in wild; Malay Peninsula [Kwal Berr, Perak, Ulu Bubong], Thailand (Beckett et al. 1965; Ridley 1923; Shellard & Lees 1965; Shellard & Walker 1969), Burma, Assam [India] (Emboden 1979a), Borneo and Papua New Guinea (Rätsch 1998).

It has been reported that this species exists in at least 2 forms or 'strains', some of which may be inactive (Torsten pers. comm. 2000). Wogg reported one with red veins on the leaves [as described above], which caused a "relaxed alertness" when chewed, and one with green veins, which was subjectively more potent according to some psychonauts (Wogg 2000). The colour difference of the leaf-veins may simply be due to nutritional factors.

To complicate matters, seeds of other Mitragyna spp. are sometimes sold as M. speciosa (Torsten pers. comm. 2001).

MOMORDICA and MONODORA

(Cucurbitaceae)

Momordica balsamina *L.* **(M. involucrata** *E. Meyer ex Sonder***; M. schinzii** *Cogn.***)** – balsam apple, balsamina, mokha

Momordica charantia *L.* **(M. chinensis** *Spreng.***; M. elegans** *Salisb.***; M. indica** *L.***; M. operculata** *Vell.***; M. sinensis** *Spreng.***; Cucumis argyi** *H. Lév.***; Sicyos fauriei** *H. Lév.***)** – ngoko bi-ai-kâi, shushavi, karela, cundeamor, African cucumber, bitter cucumber, bitter gourd, bitter melon, maiden apple, balsam pear, carilla fruit, cerassee, luo han guo

(Myristicaceae)

Monodora myristica *(Gaertn.) Dunal* **(M. borealis** *S. Elliott***; M. claessensii** *De Wild.***; M. grandiflora** *Benth.***; Annona myristica** *Gaertn.***)** – pebe, lubushi, owere, hikoma, medjok, mendak, nding, Calabassan nutmeg

Natives of Bassa, central Cameroon [Africa] may sometimes wish to contact the 'bisime', or water-spirits. To do this, one must visit the local curer, who administers a plant known as 'ngoko bi ai kâi' [believed to be Momordica charantia]. A preparation from the plant is both consumed and rubbed into the skin. It is presumed that psychotropic effects result, in which one sees, and may converse with, the bisime. To break off this contact, one again visits the curer, who gives another plant to be rubbed on the body. Two such antidotes have been mentioned, known by the Duala as 'mandai' or 'mandassi' [unidentified], and 'pebe', which is a name that has been applied to Monodora myristica. This latter antidote is also known to the Bassa as 'hikoma', as 'medjok' or 'mendak' to the Bamileké, and 'nding' to the Ewondo. Wagner suggested the possibility that pebe may, in this case, refer to another Myristicaceous plant, even **Myristica** fragrans itself (Wagner 1991). Unfortunately, the English summary accompanying Wagner's 1991 article confused the relationships of the plants discussed. The error has persisted for English-speakers since Ott (1993) repeated the assertion that M. myristica was possibly used to contact the water-spirits, with M. charantia used to break the contact.

Monodora myristica fruits have been used as a stimulant and nutmeg substitute [see **Myristica**], 'Calabassan nutmeg'. The aroma of the fruit is said to be similar to that of true nutmeg, but less fragrant. Central African pygmies sometimes use the seeds as a 'reconstituant', heart-tonic, and remedy for headaches and fever (Grime 1976; Wagner 1991). To treat headache, they may be chewed and rubbed on the forehead; the chewed root also relieves toothache (Bremness 1994).

Momordica charantia is much cultivated in India for its edible young fruits, which are pickled before consumption. As a food the fruit is "very bitter and has to be steeped in salt water, then well boiled and squeezed, and therefore, the removal of the upper skin, as also scraping away ridges and tubercles where bitterness is concentrated, makes the fruit more palatable" (Nadkarni 1976). Medicinally, M. charantia is used widely. In India, the fruit is considered stimulant, tonic, laxative and emetic, and "dissipates melancholia". The seeds are also used in Ayurvedic medicine, as an analgesic for gout and rheumatism, and to treat diabetes mellitus and liver disorders. The seeds and leaves of M. charantia are known to be a strong purgative and emetic; this action can be so violent, that a child has been reported to have died from it. The leaf and root have also been used to treat epilepsy, earache, fever, gout, and roundworm. In Tanganyika, the fruit pulp is used to repel or poison ants, weevils and moths. This plant and its relatives are used medicinally in parts of Africa, Asia, the Americas, and the Caribbean (Biswas et al. 1991; Chopra et al. 1965; Dale & Greenway 1961; Nadkarni 1976; Watt & Breyer-Brandwijk 1962). In TCM, the dried ripe fruit ['luo han guo'] of M. charantia (friendly pers. comm.) and/or M. grosvenori are used as an expectorant and to treat symptoms of colds (Huang 1993).

In the Philippines, M. charantia has been used to make an arrow-poison (Watt & Breyer-Brandwijk 1962). The root of M. charantia has been used as an aphrodisiac in Mexico (Heffern 1974; Jiu 1966). A hot water extract of the root has been taken as an aphrodisiac in parts of Africa; a tincture of the root is also believed to have aphrodisiac properties in Brazil. In Ivory Coast, the leaf juice is added to palm wine [see *Methods of Ingestion*] as an aphrodisiac. In Cuba, an extract of the whole plant is used by women to treat sterility. Strangely, all parts of the plant are also widely used to prevent pregnancy by early abortion. In Jamaica, the plant is infused to make a 'bush tea' [see **Camellia**]. The whole plant has also been taken in large amounts to treat diabetes (Ross 1999).

Momordica balsamina has been reported to cause feelings of lightness and appearance of 'fog' before the eyes (Wagner 1991). It has been used as an ingredient in arrow-poisons. The fruit of this species is widely considered to be very toxic, though as with M. charantia, it is edible after preparation. M. involucrata and M. foetida runners are infused or decocted by the Zulu as a sedative for an irritable stomach (Chopra et al. 1965; Watt & Breyer-Brandwijk 1962). In India, M. cochinchinensis and M. dioica are also considered to be stimulants, and M. cymbalaria is used as an abortifacient (Nadkarni 1976). Some other 'wild cucumbers' may be psychoactive – see also Echinocystis lobata in *Endnotes*.

Momordica charantia leaves have yielded 0.038% monoridicine, cucurbitane triterpenes called momordicines and momordicosides, *GABA*, a fixed oil, an essential oil, a glucoside, resins, and vitamins A & C. An extract of the leaf is antibiotic, antibacterial and insecticidal. Leaf juice showed antifertility effects in female mice. A hot water extract of unspecified parts given orally to pregnant rats inhibited foetal development. Seed has yielded 32-35% of a fixed oil with purgative properties, which consists of stearic acid, α-oleostearic acid, oleic acid and linoleic acid; as well as being high in saponins. Unripe fruit juice showed antifertility effects in male rats, and an extract of the fruit had antispermatogenic effects in various animals. Ethanol extracts of fresh fruit and leaves [given i.p.] showed CNS-depressant activity in mice. Ethanol extract of the root [given i.v.] acted as a uterine stimulant on non-pregnant guinea-pig uterus (Chopra et al. 1965; Durand et al. 1962; Fatope et al. 1990; Ross 1999; Watt & Breyer-Brandwijk 1962). Fruit, seeds and tissue cultures contain polypeptide-p, which has strong hypoglycaemic activity (Khanna et al. 1981); perhaps this effect has a role in the psychopharmacology of the plant [see **Oplopanax**]. This species has been well-studied chemically, and has yielded too many compounds to list here. Many of the compounds found in this plant are cucurbitacins [see **Desfontainia**]. A useful overview may be found in Ross (1999).

Monodora myristica seed oil has yielded mainly phellandrene, as well as cineol, limonene and myristicol (Schermerhorn et al. ed. 1957-1974; Schimmel & Co. 1904); the plant has also yielded monodoro-indole and isomonodoro-indole (Buckingham et al ed. 1994). Schermerhorn et al. (ed. 1957-1974) also listed the essential oil as containing *eugenol*, benzaldehyde, cinnamaldehyde, a ketone and an alcohol, but this appears to be a poor reading of their reference, Schimmel & Co. (1904), which does not report those chemicals in this species.

Monodora tenuifolia stems have yielded aporphine alkaloids, including anonaine, liriodenine, stepharine, magnoflorine iodide, sparsiflorine, N,O-diacetylanolobine and N,O,O-triacetyllaurelliptine (Spiff et al. 1984); leaves have yielded 2.5-3% alkaloids, 60% of which was laurelliptine (Djakoure et al. 1980). The plant has also yielded 6-(3'-methylbuta-1',3'-dienyl)-indole (Husson 1985).

Momordica charantia is an annual trailing or climbing herb, pubescent, sometimes glabrescent. Leaves palmately 5-7-lobed, the segments again lobulate or sinuate-dentate, 3-10cm long, toothed, glabrous or pubescent; petiole 3-5cm long; tendrils simple. Male flowers usually solitary, on stalk 0.5-8cm long; bract 2cm long, towards base or near the middle of flowering stalk; female flowers solitary, on a stalk 0.2-5cm long, usually smaller than males; bract 2cm long, sometimes absent; hypanthium shallow; petals 5, free, 1-3 with incurved scales inside at base, white or yellow; stamens 3; anthers free or fused; disc absent; females with 0 or 3 staminodes. Ovules numerous; stigmas 3, 2-lobed. Fruit fleshy, ovoid, 3-12cm long, with longitudinal ridges and warts, orange to red, dehiscing irregularly by 3 valves, exposing the seeds in sticky pulp hanging from the face of each valve; seeds few to many, ovate, sculptured, c.10mm long.

Cameroon; scattered throughout tropics of both hemispheres; naturalised in parts of coastal Queensland and Northern Territory [Australia] (Chopra et al. 1965; Cribb & Cribb 1987; Harden ed. 1990-1993).

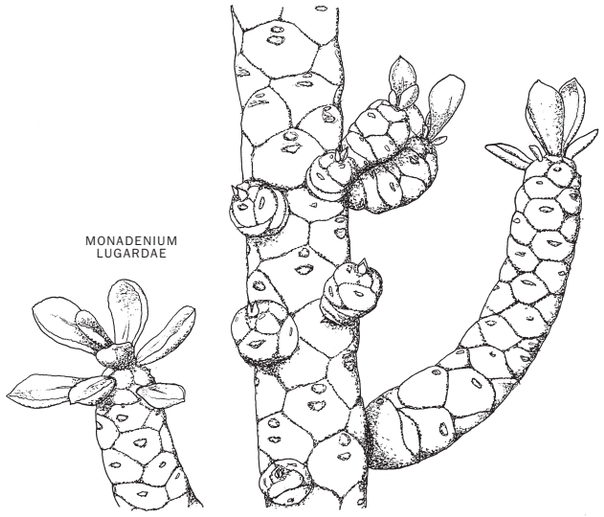
Monodora myristica is a deciduous forest tree to c.24m tall, casting heavy shade when in full leaf; bark grey, vertically corrugated, ridges distinctly rounded; slash brown, vaguely layered. Leaves glaucous, paler below than above, obovate-elliptic, to 61 x 20cm (usually not more than 20 x 6.3cm on flowering shoots), apex obtusely acuminate, base rounded with minute, characteristic, upward-directed auricles where the lamina joins the petiole, lateral nerves 12-20 pairs, prominent beneath; petiole thick, purplish, 1.3cm long. Flowers large, handsome, 10-13cm across, borne singly on short flowering branches; stalks slender, up to 20.3cm long with an ovate leafy crispate bract up to 2.5cm long in upper ½ (the stalk is re-

ally a modified branch), deciduous if the flower is not fertilised, thickening and becoming woody if it is; sepals 3, green with reddish spots, crispate, lanceolate, 2.5-3.8cm long; petals 6 in 2 series, outer petals ovate-lanceolate, to 10cm long, crispate, greenish-yellow spotted with purple-red and brown, inner petals broadly ovate, much shorter than the outer, not crispate, greenish-white with purple-brown spots, the lamina +- distinctly auricled at base, the auricles incurved, pilose; carpels whorled and united forming a 1-celled ovary with parietal placentation. Fruit smooth, green, spherical, becoming woody, c.15-18cm diam., containing numerous edible seeds, 2.5cm long, embedded in a fragrant pulp.

In riparian forest; Kenya, Cameroon (Dale & Greenway 1961).

MONADENIUM

(Euphorbiaceae)



Monadenium lugardae *N.E. Br.* – tshulu, mhlebe, mahumula

This succulent plant, sometimes cultivated as an ornamental, has been used by shamans [‘sangomas’] in the Piet Rief region of Eastern Transvaal, Africa. A piece of the root is chewed and swallowed, in order to produce visions for the purpose of prophesy. It is known to produce delirium and hallucinations with an adequate dose, though it is also said to have been lethal on occasion (De Smet 1996; Emboden 1979a; Watt & Breyer-Brandwijk 1962).

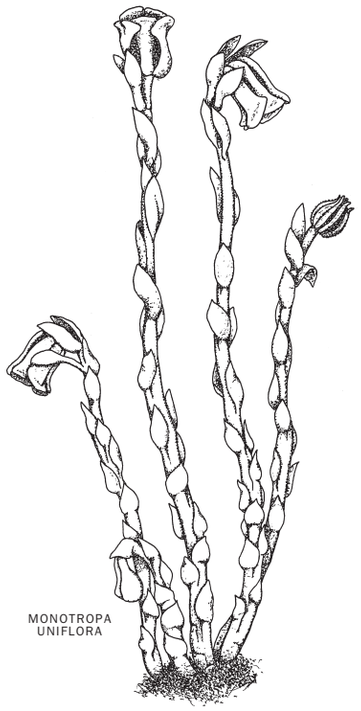
M. lugardae contains a latex with insecticidal activity, as well as an unidentified alkaloid (De Smet 1996). As with other latex-bearing plants [such as other Euphorbiaceae and many Apocynaceae], care should be taken not to bring the latex into contact with the eyes.

Monadenium lugardae is a monoecious dwarf perennial succulent, with tuberous rhizomes and milky latex. Succulent stems simple or branched at base, 10-60 x 1.5-3cm, cylindrical, glabrous, with rhomboidal or hexagonal tessellations; leaves simple, alternate, fleshy, crowded in a small terminal tuft or spaced along upper part of stem, spathulate to obovate, 1.5-9 x 0.5-4cm, margin crisped serrulate towards apex, attenuate, obtuse or subacute, subsessile, soon deciduous and leaving prominent leaf scars. Flowers greenish, in cyathia of 3 nodding involucres, arranged in solitary, axillary cymes, in uppermost leaf axils, once-forked; peduncles short, stout, 2-6mm long; involucre bracteate, cup-like, open on one side to below the middle, truncate at summit and bearing a continuous gland around its top margin, as long as the inner series of 5 membranaceous, fringe-toothed lobes, or longer; stamens 1-several. Ovary 3-celled, superior, triangular, with 2 rows of serrated wings on each ridge, becoming long-exserted on a recurved stalk. Fruit a 3-angled capsule with 2 minute, crisped-toothed wings down each angle, splitting into 3 1-seeded sections.

Arid plains and open places; s.e. Africa (Bailey & Bailey 1976; Jacobsen 1960).

MONOTROPA

(Ericaceae)



Monotropa uniflora *L.* **(Hypopitys uniflora** *(L.) Crantz***)** – pipe plant, Indian pipe, ghost pipe, ink pipe, wood snowdrop, ice plant, corpse plant, fit root, bird’s nest, xawiska, ova ova

M. uniflora is an eerily beautiful herb, with many interesting common names related to its appearance. The name ‘pipe plant’ is related to the shape of the flowers. It may be called ‘ghost pipe’ both because of its ‘ghostly’ appearance, and the fact that the plant is so delicate when fresh that it may dissolve or melt away on handling, hinting at the ethereal nature of ghosts and also explaining a probable origin of the name ‘ice plant’ (Felter & Lloyd 1898; pers. obs.).

The roots of this rare herb were used by the Cherokee to treat epilepsy and convulsions; its diluted juice was also used as a wash for sore eyes, and the crushed plant was applied externally to bunions and warts (Hamel & Chiltoskey 1975). Other native American tribes used it in a similar way, to overcome ‘nervous irritability’ and spasms. The Winnebago use it as a smudge-stick to revive someone who has fainted (Kindscher & Hurlburt 1998). In 19th century N. America, the plant was popular as an opium substitute [see **Papaver**], and was not recorded to have any negative side-effects. The root acts as a sedative, nervine, antispasmodic, diaphoretic, and tonic, and is generally used in doses of 2-4g. It soon fell into disuse, probably because of its scarcity. M. uniflora is now considered endangered (Emboden 1979a; Felter & Lloyd 1898), and should be lightly harvested if at all, for the sake of conservation. Other Monotropa spp. may have similar properties and should be explored as substitutes.

M. hypopitys has yielded the iridoid lactone glycoside monotropein, and monotropitoside [gaultherin, a methyl-salicylate derivative – see **Gaultheria**].

M. uniflora has yielded [w/w] 0.0087% monotropein, as well as ursolic acid, p-coumaric acid and β-sitosterol (Bobbitt et al. 1966). Early studies suggested that the plant contains andromedotoxin [see Rhododendron spp. in *Endnotes*] (Felter & Lloyd 1898), though this has not been verified and may have been in error.

Monotropa uniflora is a fleshy herb with a cold, waxy texture, turning black when touched or on drying; stems 10-20cm tall, usually solitary, commonly pure waxy white, rarely pink or reddish, beset with small scale-like leaves; parasitic on soil fungi. Nodding flower solitary, odourless, 10-17mm long, same colour as stem; sepals often none, or 2-5; corolla urceolate or broadly tubular; petals 4-5, distinct, all or some saccate at base, broadly oblong, slightly widened distally; stamens 8 or 10, filaments slender, pubescent; anthers transverse, opening by 2 clefts across the top. Ovary superior, 4-5-celled; style short, thick, longer than ovary; stigma glabrous, broad, peltate and umbilicate. Fruit a loculicidal capsule, erect, ovoid to subglobose. Fl. Jun.-Aug.

Rich woods in leaf mold, especially in beech and maple forests; Newfoundland to Washington, south to Florida, California and Central America; also in east Asia (Emboden 1979a; Gleason 1952). The root is harvested from Sep.-Oct., dried, and pulverised for storage in airtight

sealed containers (Felter & Lloyd 1898).

MORUS

(Moraceae)

Morus alba *L.* **(M. intermedia** *Perr.***; M. tatarica** *L.***)** – white mulberry, sang shen, toola, kambilipuch
Morus nigra *L.* – black mulberry, shetuta, shetura, tuta
Morus rubra *L.* – red mulberry, American mulberry
Morus spp. – mulberry trees

'Mulberry' is associated with the Roman fertility and nature goddess Diana, and has been used magically to make wands and to protect the garden from lightning (Bremness 1994; Cunningham 1994). In the 1500's, M. nigra was used extensively in medicine. The berries were a remedy to stop inflammation and bleeding, the bark for toothache, and the leaves as an antidote for snakebite and aconite poisoning [Aconitum spp. – see *Endnotes*]. In Europe, a leaf extract has been used to stimulate insulin production in diabetics. M. alba fruit is still used in TCM as a yin tonic to nourish the 'vital essence', and as a gentle laxative. Branches and twigs ['sang zhi'] are analgesic, diuretic, and treat rheumatism and high blood pressure; they are tranquillising in mice. Root bark ['sang bai' or 'sang bai pi'] is a sedative expectorant. The leaves ['sang ye'] are used for headaches, colds, fevers and sore throats (Huang 1993; Hsu et al. 1986; Ody 1993). Extracts of M. alba leaves have shown some antioxidant and free-radical scavenging activity (Doi et al. 2001).

Apparently, Baluchi warriors once carried M. alba berries to eat before battle, "to give them stomach for the fight" (Nadkarni 1976). Uncooked leaves and young twigs of Morus spp., as well as unripe berries, accompanying latex, and water used to cook young leaves, are reported to cause CNS stimulation, possibly with mild hallucinations, as well as headache and gastric upset (Bremness 1994; Brill & Dean 1994; Ody 1993). One book reported that "the primary hallucination is that you're so sick you're going to die. However, you'll probably recover" (Brill & Dean 1994)! Some psychonauts, using what may have been M. rubra, have reported relaxing and numbing effects from eating 20-40 unripe berries [still green]; "deliriant" effects were attributed to higher doses [c.60 berries] (R.D. 2001). Animal intoxications have also been reported. In Victoria [Australia], ducks have been observed becoming so inebriated from eating fallen mulberries, that they were "almost toppled by the wind". The writer and illustrator Beatrix Potter also recorded the results of feeding her pet rabbit a cup of mulberry seeds – "the consequence being that when I wanted to draw him the next morning he was partially intoxicated and wholly unmanageable" (Smullen 1989)!

The dried fruits of both M. alba and M. nigra [and jam from M. nigra] have been commercially available, as the fresh fruit is prone to bruising and does not travel well. The ripe fruits of both species are edible, though M. nigra fruit is often considered more delicious (theobromus pers. comm.). Some people may get contact dermatitis from the leaf (Blackwell 1990), which is grown as food for silkworms [Bombyx mori – see *Endnotes*] – the thick sap is said to give strength to the silk filaments (Bremness 1994).

Mistletoes [see *Endnotes*] sometimes grow on Morus spp., and in China they have been used medicinally. These include Viscum album var. coloratum ['hu chi sheng', 'pei chi sheng'], V. liquidambaricolum ['pien chi sheng'], Loranthus parasiticus ['sang chi sheng', 'kuang chi sheng'], L. yadoriki ['shih chi sheng'], and Scurrula ritozanensis ['tai wan chi sheng']. Collectively, they are referred to as 'sang chi sheng' or 'liu chi sheng', and are used to treat arthralgia, lumbago, stiff back, pain in muscles and tendons, vaginal bleeding in pregnancy, and other disorders, in a dose of 9-16g. They have shown hypotensive, diuretic, antibacterial, antiviral and blood-cholesterol lowering effects (Hsu et al. 1986).

M. alba root bark, fruits, and leaves have yielded a variety of alkaloids, including [as % of each part, respectively] 1-deoxynojirimycin [DNJ; a piperidine alkaloid][0.165, 0.084, 0.069], 2-O-α-D-galactopyranosyl-1-deoxynojirimycin [0.0017, 0.014, 0.03], traces of other nojirimycin-derivatives, calystegine B1 [0.00016, 0, 0], calystegine B2 [0.00083, 0.0012, 0.0026], fagomine [0.0021, 0.0018, 0.0185], and traces of other fagomine-derivatives, D-arabinitol-derivatives, 1,4-dideoxy-1,4-imino-D-ribitol and (2R,3R,4R)-2-OH-methyl-3,4-dihydroxypyrrolidine-N-propionamide. Calystegine C1 has also been found in the root bark, and the fruits yielded 2 new dihydroxynortropanes – 4-O-α-D-galactopyranosyl-calystegine B2 [0.001%] and 3β,6β-dihydroxynortropane [see **Convolvulus**] (Asano et al. 2001). The leaves have also yielded astragalin, skimmin, scopolin, isoquercitrin, roseoside, benzyl D-glucopyranoside, 2 new prenylflavanes and a glycoside (Doi et al. 2001); stems, bark and roots have also yielded morin [inhibits enzyme functions], dihydromorin, maclurin, mulberrin, cyclomulberrin, mulberrochromene, cyclomulberrochromene, 2,4,4',6-tetrahydroxybenzophenone and dihydrokaempferol [kaempferol itself is an MAOI (Sloley et al. 2000)]. A water extract of the bark had a hypotensive action in rabbits [i.v.] which was blocked by *atropine* (Huang 1993; Rastogi & Mehrotra ed. 1990-1993). Root bark showed sedative, anticonvulsant, hypotensive, analgesic, antitussive, diuretic, cathartic and antioedema activity in animals (Yamatake et al. 1976).

M. alba cv. 'Ichinose' yielded, from the reddish-violet powder of the root bark surface, 2-arylbenzofuran derivatives [including mulberrofuran M] and stilbene derivatives (Hano et al. 1986).

M. nigra root bark contains the prenylflavonoid morusin as a major component; morusin has shown analgesic effects in mice [i.p.] (De Souzaa et al. 2000b).

Morus sp. root bark [as the Chinese drug 'sang bai pi'] yielded mulberrofurans K [0.0005%], N [0.00039%] & O [0.0075%] (Hano et al. 1985).

Leaves of unspecified Morus spp. were shown to contain tyrosine, *phenylalanine*, *choline*, *glycine*, valine, *aspartic acid*, leucine, alanine, proline, guanine, adenine, histidine, arginine, lysine, trigonelline and hypoxanthine (Katayama 1917).

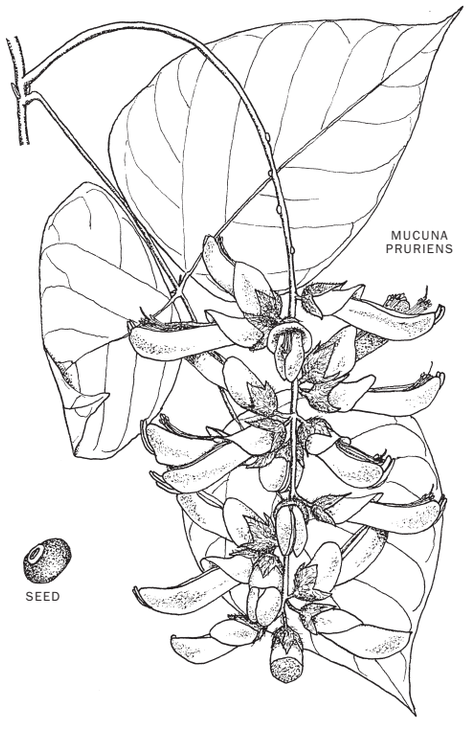
Morus spp. have also been found to contain albafuran A, albanol A [hypotensive], moracin A, kuwanone G, kuwanone H [hypotensive], mulberrofuran A, 5,7-dihydroxychromone and paeonol [anxiolytic] (Harborne & Baxter ed. 1993). The silkworms that feed on Morus spp. accumulate large amounts of some of the alkaloids of these plants (Asano et al. 2001) – see *Endnotes* for more discussion on Bombyx mori.

Morus alba is a deciduous tree to 15m tall; bark orange-brown. Leaves rotund in outline, up to 20 x 12cm, serrate, often irregularly 3- or more lobed, acute or short acuminate, often cordate at base, glabrous or nearly so on both sides, or sparsely pubescent with white spreading hairs along the veins underneath. Flowers in cylindric catkins, males longer and more loosely flowered; calyx deeply 4-parted; stamens 4; style deeply 2-parted. Fruit a short, cylindric berry cluster, white, pink or purple to almost black, composed of juicy, accrescent but not coherent calyces, each containing a small seed-like achene, with the remains of the style protruding.

Native to e. Asia [hill slopes of n. China], long cultivated in Europe and N. America; often escaped on roadsides, in vacant land and open woods (Coombes 1992; Gleason 1952).

MUCUNA

(Leguminosae/Fabaceae)



Mucuna argyrophylla *Standl.* – tecalate
Mucuna monosperma *DC.* – negro bean, mothikunile, thelu-kodi
Mucuna pruriens *(L.) DC.* **(M. aterrima** *(Piper et Tracy) Holland***; M. esquirolii** *H. Lév.***; M. prurita** *Hook.***; M. prurita** *Wight***; Dolichos pruriens** *L.***; Stizolobium pruriens** *(L.) Medik.***)** – cowitch, cowhage, buffalo bean, hellfire bean, itchy bean, fogarate, gratey, pica pica, pois-velu, pois-gratter, goncha, guru, chanda, kaochir, adhyanda, atmagupta, kiwach, kaunch, feijao macaco
Mucuna pruriens var. utilis *(Wight) Burck* **(M. capitata** *Wight et Arn.***; M. deeringiana** *(Bort) Merr.***; M. utilis** *Wight***; Stizolobium hassjoo** *Piper et Tracy***)** – velvet bean, Bengal bean, Mauritius bean, Portuguese coffee, cafe Brazilii, kafé go bouwo

M. pruriens has an interesting history of use, and contains some interesting compounds. Its seeds are an ingredient of some Haitian zombi potions, perhaps due to the irritating stinging hairs covering the seed pods [M. pruriens var. utilis is a variety with velvety hairs and no sting]. The Cuna of Panama use the seed as an aphrodisiac, a use shared in Brazil [in the form of water or alcohol extracts], where it also serves as a nerve tonic. In Nepal, it is a remedy for 'disorders of the nervous system' (Davis 1988a; Ott 1993; Ross 1999).

The plant is probably most widely used in India. There, the leaf is employed to treat headache and is considered aphrodisiac, tonic, anthelmintic, antiinflammatory and blood-cleansing. The bitter-sweet seed has similar uses, and also treats biliousness, ulcers, gonorrhoea, gout, and scorpion-stings [for which it is said to be ineffective]. The seeds are also a prominent aphrodisiac, sexual tonic, and nerve tonic, and have been used as an expectorant and abortifacient. A seed decoction has been given to children as an anthelmintic, though fatal overdoses have sometimes been reported. The root is a purgative, emmenagogue and uterine-stimulant used to treat dysentery, delirium in fevers, and elephantiasis. In Chota-Nagpur, the smoke of the root is used to accelerate delivery and lessen pain in childbirth (Ghosal et al. 1970a; Kirtikar & Basu 1980; Nadkarni 1976; Ross 1999; Watt & Breyer-Brandwijk 1962).

The seeds were once used in Hindu medicine as an aphrodisiac, combined in equal parts with **Tribulus** terrestris fruits to make a dose of c.1.8g, with sugar and milk. When you examine the chemistry of these two plants, this preparation taken in larger doses could perhaps represent an ancient 'ayahuasca analogue' of sorts [see *Methods of Ingestion*], though the potential toxicity of large levels of *L-DOPA* with MAO-inhibition might be of concern [also, the MAOI activity of **Tribulus** is currently in doubt]. M. pruriens seed is also an ingredient in an Indian compound medication for general debility, in equal parts with *camphor* [see **Cinnamomum**], 'mace' [see **Myristica**], **Argyreia** nervosa, **Acorus** calamus and sugar – the dose of the powder is c.650mg (Dutt 1989; Nadkarni 1976).

As a note of interest, in Mozambique in 1989, an outbreak of "acute toxic psychosis" occurred during a time of famine and extreme hardship, when locals subsisted almost entirely on improperly-cooked M. pruriens seed (Infante et al. 1990). As in other parts of the world where this species occurs, the seeds have been decocted and taken as an aphrodisiac in Mozambique, Madagascar [as a milk decoction – 120g seed per 1 litre of milk] and Guinea-Bissau (Ross 1999). In Mexico, M. argyrophylla seeds are used as an aphrodisiac (Jiu 1966).

There exists a modern anonymous report of mild psychoactive effects from smoking M. pruriens leaf ['1 cigarette-sized joint']. These effects were much more prominent when 2 similar cigarettes were smoked after having consumed 3g **Peganum** harmala seed – which "produced throbbing in the head accompanied by coloured geometric patterns…Pulsating coloured patterns spiralling around me, a strong urge to lie down. Very mellow and detached" (DeKorne ed. 1996).

M. monosperma seed is decocted in India as a sedative and expectorant (Usher 1974). In the Congo, twigs of M. poggei are used to stupefy fish; M. flagellipes is also used there to make an arrow poison. In Java, M. jonghuniana seeds are worn as a charm against diseases. Seeds of M. gigantea are considered edible in Malaysia (Davis 1988a; Usher 1974). The Nkopo of Papua New Guinea use a Mucuna sp. ['soal'] in rituals to promote hunting success (Schmid 1991).

Some Mucuna spp. have fruits that are covered with tiny trichomes, which may penetrate the skin and release irritating compounds that cause intense itching, burning and blistering. They contain *serotonin*, which causes *histamine* release. Their action is destroyed by boiling or drying (Allen & Allen 1981; Bowden et al. 1954; Watt & Breyer-Brandwijk 1962). In some parts of Africa, such fruit trichomes [usually referred to simply as 'stinging hairs'] have been used as a homicidal poison (De Smet 1998). Mature seeds of Mucuna spp. often contain large amounts of *L-DOPA* – besides those mentioned below, M. holtonii yielded 6.7% and M. urens 5.2%, with two unidentified species from Georgia [US] and Japan yielding 3.1% and 4.4%, respectively (Daxenbichler et al. 1971).

M. gigantea growing in Queensland, Australia, tested alkaloid-positive in the seeds [harv. Jan.]; leaf material gave a weak-positive in one test (Webb 1949).

M. pruriens seed [both ripe and unripe] and pod contain *DMT*, *DMT* N-oxide, *5-methoxy-DMT*, *bufotenine*, an unidentified β-carboline, an unidentified 5-oxyindole-3-alkylamine and an unidentified indole-3-alkylamine; seeds also contain *choline*, *L-DOPA* [c.1.5% w/w], 1,2,3,4-tetrahydro-6,7-dihydroxy-3-isoquinoline carboxylic acid, 0.025% mucunine and 0.055% mucunadine [two uncharacterised alkaloids, which might be identical to some of the above], as well as an oil containing β-sitosterol, myristic acid, palmitic acid, stearic acid, arachidic acid, oleic acid, linoleic acid and linolenic acid. Leaf [fresh] yielded 0.0064% *DMT*, 0.003% *DMT* N-oxide, 0.0025% *5-methoxy-DMT*, 0.011% *bufotenine*, 0.046% unidentified indole-3-alkylamine, the other two unidentified compounds above, and *choline*. Root also yielded these compounds (Damodaran & Ramaswamy 1937; Ghosal et al. 1970a, 1970b; Mehta & Majumdar 1946; Santra & Majumdar 1954). The stem-leaf has also reportedly yielded isoharmine [6-MeO-*harman*] (Ghosal 1972), an MAOI (Shulgin & Shulgin 1997). The trichomes of the seed pods have yielded 0.015% *serotonin* (Bowden et al. 1954). *Nicotine* [small amounts], mucuadine, mucuadinine, mucuadininine, prurienidine [vasodilator, hypotensive], prurienine [vasodilator, hypotensive, stimulates intestinal peristalsis], prurieninine [similar activity to prurienine] (Majumdar & Paul 1955; Majumdar & Zalani 1954) and Mucuna Pruriens bases P, Q, R, S and X were reported from unspecified parts (Rakhit & Majumdar 1958). As later work has not reported these uncharacterised alkaloids, perhaps they [not including *nicotine*] are identical with the known indole alkaloids mentioned above.

In an Indian study, the total indole alkaloids from M. pruriens [whole plant] produced marked behavioural changes in rats, seemingly indicating 'hallucinogenic' and stimulant activity (Rastogi & Mehrotra ed. 1990-1993). Hypoglycaemic effects have also been demonstrated in rats, from an ethanol/water [1:1] extract of the seeds; teratogenic effects in pregnant rats were also demonstrated [administered intragastrically], though a water extract of the seeds, tested in the same fashion, showed no embryotoxic effects. Ethanol/water [1:1] extract of seeds and roots showed antispasmodic activity against *acetylcholine*- and *histamine*-induced spasms, in guinea pig ileum. In humans, an extract of the dried whole plant taken regularly was shown to increase sperm count and sperm motility. Seeds with *L-DOPA* content of c.4.5-5.5%, taken orally at 15-40g, had antiparkinson activity in humans (Ross 1999).

M. pruriens var. utilis has not been found to contain indole alkaloids, but may not have been analysed for such compounds. Stems and leaves contain *L-DOPA*; leaflets have yielded the flavonoids cajanol, dalbergioidin, genistein [MAOI (Hatano et al. 1991)], 2'-OH-genistein, kievitone, maackiain and medicarpin; seed pods have yielded stizolamine, (1'S,2'R)-neopterin, isoxanthopterin, and 2-amino-6-(hydroxymethyl)-4-(1H)-pteridinone; seeds have yielded 2.3-5% *L-DOPA*, stizolamine, 1,2,3,4-tetrahydro-6,7-dihydroxy-3-isoquinoline carboxylic acid and 1,2,3,4-tetrahydro-6,7-dihydroxy-1-methyl-3-isoquinolinecarboxylic acid; and epicotyl sap has yielded stizolobic acid and stizolobinic acid [see **Amanita**] (Daxenbichler et al. 1971; International... 1994).

Mucuna pruriens is an annual twining shrub; branches slender, +-hairy at first, later glabrescent. Leaves pinnately 3-foliate; petioles 6.3-11.3cm long, appressedly silky; stipules deciduous, lanceolate, 5mm long; stipels minute; leaflets membranous, 7.5-12.5 x 5-7.5cm, terminal leaflets slightly smaller, rhomboid-ovate, base cuneate, lateral leaflets with truncate base, very inaequilateral, lower side greatly dilated, apex subacute, mucronate, pubescent above, densely clothed with silvery-grey hairs beneath. Flowers solitary or 2-3 together along a slender silky rachis, large, purple or greenish, in elongate 6-30-flowered racemes 15-30cm long, axillary or lateral on old branches or on stems; pedicels 3-6mm long, hairy; bracts 1.2cm long, lanceolate, hairy, caducous; bracteoles 8mm long, hairy, caducous; calyx 1cm long, silky, with few irritant bristles; tube campanulate, upper teeth completely connate into a triangular lip equalling the tube, lateral teeth lanceolate and as long as tube, and lower tooth lanceolate and slightly longer; corolla much exserted, 2.5-3.7cm long, purple; standard c.½ the length of the wings and keel, auricled at base; keel slightly incurved; stamens diadelphous; anthers dimorphous, the longer basifixed, the shorter ovate or bearded. Ovary sessile, villous, 2- to many-ovuled. Pods 5-7.5 x c.1.2cm, turgid, with a longitudinal rib running the length of each valve, falcately curved on both ends (somewhat S-shaped), densely clothed with persistent irritant bristles which are at first pale brown, later steel grey. Seeds 5-6, small.

Cosmopolitan in the tropics, often cultivated (Kirtikar & Basu 1980); India, China, Philippines, Taiwan, Australia [Qld], Caribbean, Central America, Brazil, Surinam, Venezuela, US, Africa, Madagascar, Mauritius (International... 1994).

MUSA

(Musaceae)

Musa sapientum *L.* **(M. paradisiaca** *L.***)** – banana, kadali, mochaka, vasha, gemeiner pisang

Musa spp. – banana palms, banana trees, plantains

The banana tree is used in modern voodoo rites to represent the gods, due in part to its hermaphroditic flowers. In Hawaii and Tahiti, the banana tree was used extensively in religious ceremonies – the fruit as an offering, the leaves to cover the altar, and the stalk as a representation of man. Until 1919, Hawaiian women were forbidden to eat bananas by threat of death. The tree is believed to increase fertility, and the stem and fruit have been used to treat general debility, asthma, stomach disorders and throat infections. The leaves are used as a poultice for wounds, and as a food wrapping for cooking. The Chewa of Africa use the stem juice to relieve toothache, and in Durban, S. Africa, the juice of black stems is taken diluted with water to sober up an intoxicated person. In India, the root, in a cold infusion, is similarly taken to sober up a drunk person; children who have overdosed on opium [see **Papaver**] are given the bark and leaf juice with ghee as a purgative. The leaves are sometimes used in country

areas as wrappers for bidi cigarettes [see **Datura**, **Nicotiana**]. Banana fruit has also been used as a remedy for diarrhoea and abdominal inflammations, as well as inhibiting the growth of some fungi and bacteria (Cunningham 1994; Nadkarni 1976; Wagner et al. 1990; Watt & Breyer-Brandwijk 1962). The Nkopo of Papua New Guinea use M. sapientum ['golda'] as a paste with other plants, in rituals to achieve harmony with natural forces (Schmid 1991).

Many will remember the banana-smoking 'craze' of the mid-late 1960's, when it was claimed that smoking a concentrated and dried water extract of ripe inner-peel scrapings, or the dried scrapings themselves, would result in a **Cannabis**-like 'high' due to the mythical psychedelic claimed to be contained within, 'bananadine'. In San Francisco, one man even started a business ['Mellow Yellow Co.'] to sell 14g portions of baked banana peel scrapings, and to give away the fruit flesh to 'underfed hippies'. This strange fad is often thought to have originated from the 1966 UK hit by Donovan, 'Mellow Yellow', with lyrics such as "electrical banana is gonna be a sudden craze" (Krikorian 1968; McCarthy 1971; Moore 1967; Weil 1969).

The idea of smoking banana peels may have actually originated with the Berkeley psychedelic band Country Joe & the Fish under amusing circumstances. I will give the story in some detail, for the sake of clarifying an 'urban myth'. As related by ['Country'] Joe McDonald – "our drummer, Gary 'Chicken' Hirsch, said he had just figured out that banana peels have qualities similar to marijuana. His theory was that if you dried out a banana peel and smoked the white pulp on the underside, you would get high. At that time, the band was living on peanut-butter-and-banana sandwiches. All the ingredients were cheap. We were just throwing the peels away, so this sounded like a great idea." At this point, the band was preparing to play a gig in Vancouver, and used the oven in a nearby 'psychedelic shop' to dry out their banana peels at low heat while they prepared for the show. Here enters the complication – the stage roadies were in possession of a jar of water dosed with a large quantity of LSD, which they offered to share with the band. Having taken several helpings and played the first set, by the time the banana peels were dry enough to smoke, their subjective judgement of the effects [or lack of] was understandably impaired. After more LSD, and another set, the band members returned to smoke more banana peels, this time convinced that they worked. McDonald – "We started puffing the banana joints and looking at each other and saying, 'Man, this shit is really working! I'm getting really ripped! This stuff is incredible!' Afterward, we went all over Vancouver telling people that bananas get you high. We returned to the Bay Area and almost immediately played a benefit to legalise marijuana. At that event, we passed out 500 banana joints and told everybody that bananas get you high." A few days later, bananas were almost impossible to find in the area, and newspaper headings proclaimed the 'New Hippie Craze'. It wasn't until 3 months later that McDonald remembered the LSD that had been involved, and thought [in his own words] "Ah, that explains everything!" (Perry & Miles 1997).

In experience, a large amount is usually required to be smoked, and the material does not burn easily; effects, though quite mild and short-acting, could well be explained away as carbon monoxide intoxication (pers. comms.). It should be borne in mind, though, that Musa spp. contain a wide array of neurotransmitters and related substances which might contribute to any psychoactive effects when concentrated and smoked, if they were able to survive combustion and cross the blood-brain barrier via this route.

M. sapientum fruit contains *5-hydroxytryptophan*, *serotonin* [% as found in hard green; ripe; over-ripe fruits, respectively – outer peel (0.0074; 0.0096; 0.016), inner peel (0.0013; 0.0038; 0.017), pulp (0.0024; 0.0036; 0.0035)], 0.0065% *tyramine* [0.0029% in fruit peel in one study, 0.0003% in leaf], 0.07% *dopamine* [ripe fruit – 0.02-0.074% in peel, 0.0022-0.005% in pulp], *norepinephrine* [ripe fruit – 0.0017-0.0084% in peel, 0.00014-0.0006% in pulp], *phenethylamine* and *histamine*, as well as the THIQ *salsolinol* [in ripe fruit – traces to 0.027% in peel, traces to 0.004 in pulp], which was found here for the first time in plant matter (Duncan et al. 1984; Riggin et al. 1976; Udenfriend et al. 1959; Watt & Breyer-Brandwijk 1962; Wheaton & Stewart 1970), and up to 0.000074% 1-methyl-1,2,3,4-tetrahydro-β-carboline-3-carboxylic acid (Herraiz 1999); peel also has yielded 0.0036% cycloartane triterpenes (Akihisa et al. 1998), and the fruit contains vitamin A, B complex vitamins, vitamin E, vitamin G, potassium, sugars and malic acid (Watt & Breyer-Brandwijk 1962). The mysterious psychoactive alkaloid 'bananadine', which has been claimed in some underground literature [such as 'The Anarchist's Cook Book'] to be the active 'psychedelic' in banana peels, is a complete fabrication.

Musa sapientum is a polymorphic plant 2-10m tall, with clear sap; pseudostems (the stem is composed of the overlapping bases of the leaves) variously coloured, 1-6m long, 15-40cm diam. at base. Leaves usually 8-20, glaucous, blades 100-400 x 30-80cm, entire, becoming torn in strips by the wind; petioles 30-100cm long. Inflorescences spreading apart, fruiting axis curved, 80-250cm long, 4-8cm diam.; female flowers few to c.20, 5-9cm long, inflated, producing thick, jelly-like nectar; male flowers numerous, 3-6cm long, narrow, compactly arranged beneath leathery red-purple bracts. Fruit of variable appearance, elongate-cylindrical, straight to strongly curved, 3-40 x 2-8cm, apex and base tapered, rounded or blunt, skin thin and tender to tough and leathery, yellow, green or red, flesh starchy to sweet, white, yellowish or orange, often seedless.

Cultivated in tropical areas from eastern India throughout s.e. Asia to the Solomon Islands and n.e. Australia, as well as the West Indies, Central America, Hawaii, Fiji, and w. & s. Africa. Naturalised in many of the countries in which it grows. Cultivated bananas are sterile hybrids bearing edible seedless fruits, mostly derived from M. sapientum (Harrison et al. 1985; Wagner et al. 1990).

MYCENA [including Gerronema]

(Agaricaceae/Tricholomataceae)

Mycena amicta *(Fries) Quélet*
Mycena cyanescens *Velenovsky*
Mycena cyanorrhiza *Quélet*
Mycena epipterygia *(Scop. ex Fr.) Gray*
Mycena pachyderma *Kühner*
Mycena pelianthina *(Fr.) Quél.*
Mycena pura *(Pers. ex Fr.) Kummer* – lilac Mycena, clean Mycena, pure Mycena, amethyst agaric
Mycena splendidipes *Peck* **(M. epipterygia var. splendidipes** *(Peck) M. Geest.***)**
Mycena subcaerulea *(Peck) Sacc.*
Gerronema fibula *(Bull. ex Fr.) Singer* **(Mycena fibula** *(Bull. ex Fr.) Kühn.***; Omphalina fibula** *(Bull. ex Fr.) Kummer***; Rickenella fibula** *(Bull. ex Fr.) Raith.***)** – orange nail fungus
Gerronema setipes *(Fr. ex Fr.) Singer* **(G. swartzii** *(Fr. ex Fr.) Kriesel***; Mycena swartzii** *(Fr. ex Fr.) A.H. Smith***; Omphalina swartzii** *(Fr.) Quél.***; Rickenella setipes** *(Fr.) Raith.***; R. swartzii** *(Fr.) Kuyp.***)**

These tiny mushrooms have gained some attention due to the bluing reaction of some species; also, a species tentatively identified as M. cyanorrhiza, as well as a Mycena sp. which was possibly M. amicta have been said to contain *psilocybin* and/or *psilocin* based on bioassays. These species, as well as M. cyanescens and M pura, sometimes show a blue bruising reaction, hinting at the possible presence of *psilocybin* and/or *psilocin* [see **Psilocybe**]. However, researchers have failed to find these tryptamines in the above mentioned species (Allen et al. 1992; Ott 1993; Stamets 1996). Also reported to blue at the base of the stem are M. pachyderma and M. subcaerulea (Breitenbach & Kranzlin 1991). Bluing in mushrooms is not necessarily related to the presence of *psilocybin* or *psilocin* [see **Boletus**], and human bioassay is not adequate to determine the chemical content of an unanalysed species.

Of these species, only M. pura has been reported to have caused 'poisonings' described as "in the narrow sense hallucinogenic" (Bresinsky & Besl 1989). Some regard this species with suspicion, when searching for edible fungi, though others claim that it is edible. In 1959, V.H. Etienne decided to find out, and consumed 40 fresh specimens of M. pura. An hour after ingestion, profuse sweating manifested, lasting for the next 3 hours. After 2 hours, there was mild nausea and colic, and marked salivation, leading into a semi-somnolent state in which Etienne experienced vivid, colourful, abstract visions. Sleep followed, and the next morning there were no side-effects noted other than mild fatigue. In 1961, R. Heim followed this up by ingesting 3.5g dry M. pura, though no effects were observed with this dose (Heim 1963b).

M. pelianthina is suspected of having toxic properties similar to those of M. pura. M. rosea has caused poisonings related to its muscarine content [see **Amanita**, *Neurochemistry*] (Bresinsky & Besl 1989). M. epipterygia and M. splendidipes have also been claimed to have 'narcotic' properties similar to those of M. pura (Norland 1976).

M. haematopus has yielded haematopodin, an indole-derived rose-coloured pigment with a chemical structure similar to dehydro-*bufotenine* [see **Arundo**, **Bufo**]; this species bleeds dark red when cut (Baumann et al. 1993).

M. metata has been shown to produce the inebriating solvent chloroform, which is released into soil-air (Hoekstra et al. 1998).

M. pura from Japan [harv. Sep.] yielded [w/w] 0.055% L-γ-methylene-*glutamic acid*, 0.0008% L-γ-ethylidene-*glutamic acid* and 0.009% L-γ-propylidene-*glutamic acid* (Hatanaka & Katayama 1975). These compounds might possibly be psychoactive. (2S,4R)-4-methyl-*glutamic acid* is a potent ligand at kainate receptors, (2S,4S)-4-methyl-*glutamic acid* is a potent ligand at 1α and 2 subtypes of *glutamic acid* receptors, and 4-methylene-*glutamic acid* is a potent non-selective ligand at kainate, AMPA, NMDA, and 1α and 2 subtypes of *glutamic acid* receptors [see *Neurochemistry*] (Bräuner-Osborne et al. 1997). Small levels of muscarines have been found, though 75-96% of this was present as epi-muscarine, which is apparently pharmacologically inactive (Bresinsky & Besl 1989; Stadelmann et al. 1976). Cultures have been shown to produce paraquinonic acid, a compound that may be useful in treating leukaemia (Clive et al. 2001).

M. pelianthina also contained small amounts of muscarines, entire-

ly present as epi-muscarine (Bresinsky & Besl 1989; Stadelmann et al. 1976).

The closely related Gerronema fibula and G. setipes [often misspelled as G. solipes] were shown to contain *psilocybin* and *tryptophan* (Gartz 1986b), though subsequent tests failed to duplicate this (Stijve & Kuyper 1988). Mycelial cultures of G. fibula have produced striatal D, a highly cytotoxic diterpenoid. Mycelial cultures of an unidentified N. American Gerronema sp. produced gerronemins A-F, biscatechols which also have cytotoxic properties (Silberborth et al. 2002).

Mycena cyanorrhiza has a cap 3-10mm across, hemispherical, campanulate, sometimes slightly indented in centre, surface dull, smooth and finely pubescent, striate almost to centre, light grey-whitish to grey-brownish; margin acute and slightly undulating regularly. Stem 10-20 x 0.2-1mm, cylindric, sometimes bent, surface finely pubescent, translucent grey-whitish, hollow, base sometimes slightly thickened and bulbous and an intense blue, tomentose, often attached to the substrate by fine anchor hyphae. Flesh membranous, taste and odour largely lacking. Gills white to grey-whitish, broad and ventricose, 10-12, with 1(-3) lamellulae between each, abruptly adnexed to almost free, edges white and sometimes peelable as an elastic thread. Spores elliptic, smooth, hyaline, with drops, 6-7.8 x 3-5µm, whitish. Fr. spring-autumn.

Usually gregarious, on dead wood or on bark of conifers; Europe. Uncommon (Breitenbach & Kranzlin 1991).

The European M. pura is also found in Australia in pine litter [Western Australia, New South Wales, Queensland], where it is "suspected of being slightly poisonous" (Shepherd & Totterdell 1988; Young, T. 1994).

MYRISTICA

(Myristicaceae)

Myristica argentea *Warb.* – New Guinea nutmeg, long nutmeg
Myristica fragrans *Houttyn* – nutmeg tree, jati-phalam, jaiphal, jaepatri, bushpala, sauz-bawwa, dzaa-ti, madashaunda ['narcotic fruit'], ram patri ['fruit of the gods'], jai patri
Myristica malabarica *Lamk.* – Malabar nutmeg, Bombay mace, kamuk, malati, kanagi
Myristica succedanea *Blume* – pala maba

Nutmeg, the seed of Myristica fragrans, and 'mace', the bright red arillus around the seed, are both common spices and powerful intoxicants. Originating in the East Indies, nutmeg had spread to Europe by at least the Middle Ages, initially via Arabian traders, and was a highly valued commodity in the lucrative spice trade [which actually catered for the demand for narcotics, aphrodisiacs and medicines, rather than culinary uses]. Often false nutmegs carved from wood would be sold as real nutmegs. For centuries, the Dutch ruthlessly monopolised its supply and distribution. The nut and its essential oil were well-known for their intoxicating properties, and have been used almost worldwide accordingly. Nutmeg became commonly used in Europe as a soporific, aphrodisiac and mild analgesic. It is apparently powdered and snuffed in some parts of Indonesia. The Malayans prescribe it for madness. In Tibet, it is inhaled, alone or with other herbs, to treat depression and other neurotic symptoms, anxiety, restlessness and palpitations. Kirati shamans of Nepal use it for shamanic travel, with 1 nutmeg being sufficient to 'fly'; it is also used as an offering. Some Hindus of w. India take it as an intoxicant, and it is given in small amounts as a hypnotic for 'irritable' children. It is much used in Indian medicine, and is sometimes substituted by M. malabarica, which is also a stimulant and nervine aphrodisiac. Its use is still sometimes apparent in prisons where no other drugs are available; its use by students, teenagers and older experimenters has also been documented (Clifford 1984; Emboden 1979a; Faguet & Rowland 1978; Lawless 1994; Müller-Ebeling et al. 2002; Nadkarni 1976; Siegel 1976; Weil 1965, 1967a, 1967b, 1969; Weil & Rosen 1983). The pickled bark of M. fragrans is known to induce sleep (theobromus pers. comm.).

The Nkopo of Papua New Guinea use what was tentatively identified as a Myristica sp. in their initiations (Schmid 1991). Interestingly, in India, birds-of-paradise have been observed "becoming so intoxicated from the mere whiff of nutmeg that they finished up lying prone with ants crawling all over them" (Smullen 1989)!

Medicinally, nutmeg in smaller amounts treats flatulence, nausea, indigestion, diarrhoea, and insomnia; it also stimulates the appetite, and is used sparingly in many sweet and savoury dishes. The essential oil is used in perfumes, soaps, hair oils, tobacco [see **Nicotiana**] and fumigants; the fixed oil, when freed of lingering essential oil ['nutmeg butter'] is used in skin creams (Bremness 1994; Nadkarni 1976; Tierra 1988). Nutmeg must be ground for use – this is preferably done when it is to be used, as ground nutmeg loses its essential oil content rather quickly (Weil 1967a).

Aromatherapists consider nutmeg essential oil to have analgesic, aphrodisiac, calming, 'elevating', euphoric, narcotic, nervine and heart tonic effects (Lawless 1994). Sedative and weak analgesic effects have been demonstrated in animals (Grover et al. 2002). In mice, nutmeg [various extracts given i.p.] has been found to produce anxiety (Sonavane et al. 2002). The nutmeg itself is stupefying in large doses, and can cause delirium, hallucinations, fainting, nausea, vomiting, severe abdominal pain, sweating, decreased body temperature and headache. Sometimes the toxic effects are exhibited during the inebriation, sometimes not until the next day; for a lucky few, not at all! Ground nutmeg is usually taken by swallowing 2-3 tablespoons [or 2-3 nutmegs] or more (pers. comms.; pers. obs.); doses of up to 80g ground nutmeg have been reported in medical literature (Stein et al. 2001). It is usually washed down with a liquid, as it doesn't dissolve in drinkable fluids. Blending the nutmeg into a cashew milkshake has been suggested as a good method, both for taste, and ease of ingestion. Effects may take up to 3-5 hours or more to manifest, lasting up to 12 hours. Responses may vary widely between individuals, and at different times, only partly due to chemical variation in the nutmegs. The side-effects stop most people from coming back, although some claim to obtain only positive effects and adopt it as a favourite substance (pers. obs.; pers. comms.; Faguet & Rowland 1978). Nutmeg may also be smoked [this is difficult and HOT] for a very mild effect (pers. obs.; pers. comm.). Anecdotal evidence suggests that smoking nutmeg may be extremely destructive to the lungs (pers. comm.).

The effects from whole ground nutmeg differ from those of nutmeg essential oil. Whole ground nutmeg, as noted above, can produce a variety of toxic effects in the doses required for psychoactivity. The essential oil appears to predominantly rely on *myristicin* and *safrole* content of the aromatic ether fraction for its psychoactivity [and perhaps also the other trace phenylpropenes – see below], and has been bioassayed in doses of up to 20ml, an amount much higher than would be found in a psychoactive dose of nutmeg. It appears that other compounds present in whole nutmeg contribute to the full spectrum of psychoactivity. Essential oils low in *myristicin* required much greater doses to reach the same level of effect; however, 20ml of one essential oil sample that was found to be low in both *myristicin* and *safrole*, taken internally, produced only the toxicity normally associated with whole ground nutmeg. Some of these toxic symptoms from the essential oil may be due to irritating effects from the terpene hydrocarbon fraction, which constitutes most of the essential oil. Humans given nutmeg devoid of essential oil experienced no psychoactivity (Shulgin et al. 1967; theobromus pers. comm.; Torsten pers. comm.).

The phenylpropenes found in the aromatic ether fraction of the essential oil have been thought to contribute to most of the psychoactivity [as mentioned above], presumably by partial or full conversion by the liver to their respective psychotropic *amphetamine* counterparts through amination, though this has not been demonstrated in humans [see *Chemical Index*]. These constituents seem to work synergistically, having relatively little activity on their own (Braun & Kalbhen 1973; Oswald et al. 1971b; Shulgin et al. 1967).

To obtain optimum positive effects from eating nutmeg, it is suggested to eat the dose on an empty stomach, following this with a carbohydrate-rich meal 1hr later. If using the essential oil, 10-15 drops may be taken orally, though some experience no effects consuming the oil directly. Massaging the essential oil into calf-muscles [if intending to dance or run] seems to result in particularly good effects. Muscle activity may stimulate the conversion of phenylpropenes in the essential oil to their *amphetamine* counterparts (Torsten pers. comm.); perhaps this is partly due to providing the oxidative conditions which may enhance the metabolic conversion (eg. see Braun & Kalbhen 1973). Consumption of large amounts of nutmeg has led to deaths in the past, due to "fatty degeneration of the liver" (Faguet & Rowland 1978). A later source claimed that there had been no reports of nutmeg fatality except for a recent case, in which the deceased had also taken flunitrazepam, possibly resulting in a dangerous interaction that might have caused the death (Stein et al. 2001).

M. argentea seeds give only a small yield of essential oil, of low quality, though this has not stopped them being sold in the spice trade.

M. canarica and M. malabarica seeds have been found to contain little essential oil, and yield mainly fats and myristic acid (Shulgin et al. 1967).

M. fragrans nuts [seeds] have yielded 5-15% essential oil, containing 3.86-12.78% *myristicin*, 0.02-2.36% *elemicin*, 0.11% isoelemicin, 0.3-3.42% *safrole*, 0.17% *eugenol*, 0.62% *methyleugenol*, 0.25% methoxyeugenol, 0.19% isoeugenol, 60-80% d-camphene, 8% dipentene, *pinene*, sabinene, geraniol, d-*borneol* and l-terpinol, as well as small residual amounts of fixed oil [2.87% myristic acid, 3.72% unidentified compounds]; and 25-40% fixed oil, consisting mainly of myristic acid, as well as trimyristin [anxiogen, apparently acting at least partly through *serotonin* and *GABA* receptors (Sonavane et al. 2002)], linoleic acid, oleic acid, and other minor constituents. The fixed oil may sometimes contain some additional essential oil in traces. The aril ['mace'] yields 4-14% essential oil of similar composition, with *myristicin* being the main phenylpropenoid constituent, and a high *safrole* content [c.1.9% of essential oil]; 1.57% malabaricone B and 0.53% malabaricone C [both antimicrobial] have also been found. Pericarp, minus aril and seed, has yielded 2-3% essential oil, containing 15.5% α-terpineol, 15.2% α-*pinene*, 13.5% terpinen-4-ol, 6.8% β-*pinene*, 4.5% isoeugenol, 1.5% *safrole*, 1% *myristicin*, 0.2% *elemicin*, 0.1% *methylisoeugenol*, 0.1% *borneol*, and many other constituents. Leaves have yielded c.1.5% essential oil, +- of the same composition as the seed (Budavari et

al. ed. 1989; Choo et al. 1999; Hall 1973; Morton 1977; Orabi et al. 1991; Shulgin et al. 1967; Weil 1967). Nutmeg and *myristicin* have a weak MAOI effect (Truitt 1967; Truitt et al. 1963). A remedy for nutmeg poisoning is administration of mineral or castor oil, followed by gastric lavage and demulcents (Turner & Szczawinski 1991).

M. succedeana has been used as a source for nutmeg essential oil where M. fragrans is not readily available, and has similar constituents (Shulgin et al. 1967).

Myristica fragrans is a tree up to 15(-18)m tall, spreading, dioecious (occ. monoecious), with superficial roots; bark grey. Leaves alternate, estipulate, short-petiolate, prominently pinnatinerved (8-11 pairs), glabrous, elliptic or oblanceolate, apex acuminate, base acute, dark green, shiny above, much paler beneath, 5-15 x 2-8cm, aromatic. Staminate and pistillate inflorescences similar, few-flowered (1-10 in staminate; 1-3 in pistillate), axillary umbellate cymes; peduncle up to 1.5cm long; flowers usually unisexual, v. rarely hermaphroditic, fragrant, yellow, waxy, fleshy, glabrous, apetalous; calyx campanulate, basally nectiferous, with 3 triangular lobes, acute, reflexed. Staminate flowers 6-7mm long; stamens 8-12; anthers adnate to central column and laterally connate to each other. Pistillate flowers up to 1cm long; ovary sessile, puberulent, 1-celled; stigma short, bifid. Fruits drupaceous, pyriform, or occasionally subglobose, nodding, yellowish, to 10cm long, longitudinally with circumferential groove along which yellow pericarp splits into 2 valves at maturity; seeds dark brown-purple, shiny, ovoid, 2-3cm long, enclosed in bright red or orange-red laciniate aril forming close network around seed.

Thought to be native to e. Malaysia; cultivated, little-known in the wild. There are about 6 races of this species with slightly differing characteristics (Schultes & Hofmann 1980).

Cultivated in the tropics, often interspersed with other tree species; prefers altitude below 750m [or up to 900m with wind protection], temps. of 10-35°C, 150-300cm average annual rainfall, and well-drained, loamy soil. Seeds lose viability quickly, and are preferably sown as soon as having been extracted from the fresh mature fruit and dried. Sow seeds in shaded raised beds [or in pots, 1 per pot], with micropylar end pointing upwards, 2.5cm deep and 12-30cm apart; water regularly. Most seeds germinate within 45-90 days. Pot out seedlings when 6 months old, and transfer to prepared ground when 1 year old. When transplanting, care must be taken not to damage the extensive root systems, particularly the tap root. Shade and water regularly for first few years of establishment. Mulching around the base of the plant with dead leaves, and fertilising with manure twice a year is advantageous. Trees bear fruit when 7 years old, with yields increasing until 20 years old; trees can remain productive of fruit for 70-80 years, and a single tree may produce 2,000-3,000 [or even up to 20,000] fruits per year. Having too many male plants in a plantation is considered undesirable; this is sometimes remedied by grafting female plants onto rootstocks of the males.

Fruits are usually harvested in the mornings, in June-October, though some report December-May as the preferred season; however, fruit may be produced all year. The fruits may take 6 months to ripen, from the time of pollination; when ripe, they split open to reveal the mace and nutmeg. The fruits are either harvested when freshly fallen to the ground, or while still on the tree, having just split open, with the aid of hooks on the end of poles. The pericarps are removed and discarded. The aril ['mace'] is removed from the seed, flattened between boards, and sun-dried separately over 10-15 days, becoming brittle; further drying over 6 weeks in total results in the amber-coloured mace of commerce. The seeds may take 4-8 weeks to dry properly, this being judged by the kernel [the 'nutmeg'] rattling inside the shell when shaken. The shell is cracked open with a mallet to remove the nutmeg (Ilyas 1978).

MYRTILLOCACTUS

(Cactaceae)

Myrtillocactus geometrizans *(Mart.) Cons.* **(Cereus geometrizans** *Mart.***; C. pugioniferus** *Lemaire***; C. gladiator** *Otto et Dietrich***)** – garambullo, padre nuestro, blue myrtle

This common Mexican cactus has acidic fruits known as 'garrambullas', which may be eaten either fresh or dried; they are often sold in local markets (Britton & Rose 1963; Bye 1979a).

M. geometrizans has been stated to contain *mescaline* (Shulgin & Shulgin 1997), though this appears to be in error. A stock of M. geometrizans that had been used to graft **Lophophora** williamsii yielded 0.3% *mescaline*, but otherwise none was found in the species (Siniscalco 1983). The *mescaline* that was detected may have originated from the location of the graft. In a broad alkaloid screening one sample tested positive for the presence of alkaloids, though another, which was flowering and fruiting, did not (Fong et al. 1972). An assay of the genus found no alkaloids, but detected triterpenes in all species. M. geometrizans yielded the triterpenes chichipegenin [0.62%], methyl-cochalate [0.25%], methyl-myrtillogenate [0.14%], longispinogenin [0.0025%] and cochalic acid (Djerassi et al. 1957), which might all be artefacts of the extraction process. It has been noted that Djerassi's screening method for detection of alkaloids may have been inadequate for the detection of *mescaline* and similar alkaloids (Trout pers. comm.).

Myrtillocactus geometrizans is a tree-like cactus, with a short definite trunk crowned by a large, much branched top; branches often a little curved, bluish-green, usually 5-6 ribbed, 6-10cm diam., very blue when young; ribs 2-3cm high, rounded; areoles 2-3cm apart; radial and central spines very different, almost filling the areoles; radial spines usually 5, rarely 8-9, usually short, 2-10(-30)mm long, +- turned backward, slightly flattened radially but swollen at base; central spine elongated, dagger-shaped, flattened laterally, 1-7cm long, sometimes 6mm wide. Flowers appearing from upper part of areole, 2.5-3.5cm wide, limb 3-4 times as long as tube; perianth segments oblong, 1.5cm long; stamens numerous, erect, exserted; fruit ellipsoid to subglobose, edible, purplish-bluish, 1-2cm long.

Very common on Mexican tableland; San Luis Potosi to Oaxaca (Britton & Rose 1963).

NAJA and OPHIOPHAGUS

(Elapidae)

Naja naja *L.* – Asian cobra, Indian cobra, spectacled cobra, common cobra, nulla pambu ['good snake'], nag, naga, nagara havu, nale pambo, moorkhan pambu, gokhura

Ophiophagus hannah *Cantor* – king cobra, royal cobra, nagaraja, krishna nagam, shankha chur

The generic name of the 'true' cobras [Naja spp.] is taken from the Nagas of Indian mythology, 'snake-deities' with the ability to give people special healing knowledge and other insights. An Indian myth tells of Mucilinga, king of the Nagas, who used his hood to shield Buddha from the sun's scorching rays when he fell asleep travelling in the desert. In thanks, Buddha blessed the serpent by touching two fingers to its neck, giving rise to the 'spectacles' on the cobra's hood (Bauchot ed. 1994). In Shirala, west-central India, local villagers believe that Shiva granted a favour to one of their ancient sages that the people would be protected from cobras, which are very common in the fields. These people see the cobra as an emblem of divinity and do not fear it – in return, the people are not harmed by these venomous but [normally] passive snakes (Miller, H. 1970). Cobras are also venerated as sacred in many other parts of India and Nepal, and numerous Hindu deities and ancient kings have been depicted with cobra hoods, or otherwise in association with cobras. As shamanic animals as well as deities, they [and other snakes] are associated with both death and renewal of life, and the links between worlds, as well as the kundalini serpent [see *Influencing Endogenous Chemistry*] (Deoras 1971; Müller-Ebeling et al. 2002).

Some saddhus and yogis in India smoke the dried venom glands or dried venom ['bis', 'vis' - names which apply to all poisons] of either N. naja or O. hannah, mixed with **Cannabis**, in order to enter a trance-like state for shamanic travel, or to gain 'shakti' [spiritual power]. **Cannabis** may also be planted on a freshly dead cobra [buried to ritual specifications] to result in very potent and visionary **Cannabis** flowers. Some adepts, including Ojha and Tharu shamans of Nepal, may even allow a cobra to bite them on the tongue or elsewhere for the same purpose; amongst the Ojha, a special mantra protects them from dangerous effects. Apparently all poisonous snake species may be used to aid shamanic travel (Müller-Ebeling et al. 2002; Rätsch 1992; Svoboda 1986).

A modern report exists of human experimentation with N. naja venom. The subject smoked a minute [ie. barely visible] amount of dried venom in a glass pipe. Effects manifested almost immediately, with confusion, delirium and 'irrational' behaviour, accompanied by immobility, increased body temperature, weak pulse and respiration, and a semi-comatose state. The subject experienced bizarre hallucinations and out-of-body sensations, and reverted to normal condition after 2 days (pers. comm.). Another report, this time of an unintentional ingestion, comes from herpetologist Carl Kauffeld, who was bitten by a large cobra. He reported a mild 'dopey' feeling with general weakening, followed by loss of alertness and a fuzzy 'darkening' around the visual field, and a feeling of being semiconscious. No swelling, burning or serious pain occurred (Mara 1993).

Today, purified and diluted cobra venom is sometimes used by doctors to treat arthritis pain (Bauchot ed. 1994) and epilepsy. In India, it has been said that "of all the stimulants, the fresh venom obtained from strong, young, black cobra is regarded as the most powerful, and its effects lasting more than those of other stimulants". Cobra venom has been taken orally in small doses by some people in India, to protect against poison and disease (Nadkarni 1976). In the past it has been used to treat leprosy (Müller-Ebeling et al. 2002). Poisonous snakes in general have been consumed in Arabic countries as a panacaea which reputedly makes one "invincible to wounds, bestows eternal youth, and allows you to understand the language of the animals" (Madejesky, in Müller-Ebeling et al. 2002).

The dry venom of N. naja consists of 90-92% proteins, and some salts. Each venom constituent is associated with a protein fraction, yielding a neurotoxin, hemolysin, cardiotoxin, cholinesterase, AChE, as well as var-

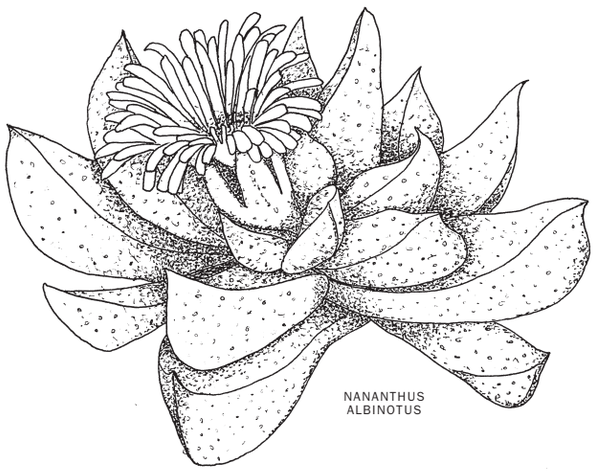
ious other enzymes and enzyme-inhibitors. The neurotoxins in N. naja venom are complex polypeptides, and are considered highly toxic. Cobra venom inhibits *acetylcholine* biosynthesis, and promotes high activity of the enzymes AChE, L-amino acid oxidase, alkaline phosphomonoesterase, phosphodiesterase and 5'-nucleotidase; low activity of the enzymes phospholipase A and hyaluronidase; and very low activity of protease enzymes (Bauchot ed. 1994; Ghosh & Chaudhuri 1968; Ohta et al. 1981; Tan, N.-H. et al. 1987). Venom obtained in winter is less toxic than venom obtained in summer. Cobras also yield less venom in captivity, though those allowed to roam outdoors produce more venom than those confined to cages or enclosures (Deoras 1971). In animals, "the venom produces initial stimulation of the higher parts of the brain followed by paralysis". Respiratory paralysis, in particular, is a real danger with the use of cobra venoms (Nadkarni 1976). In an 'average-sized' male human, 12mg of cobra venom may be lethal (Deoras 1971).

In the case of a cobra bite, the symptoms usually manifest within 1-4 hours, beginning with drooping eyelids and a feeling of sleepy intoxication; following symptoms may include respiratory difficulty, paralysis of eye muscles, increased salivation, weakness of neck and limbs, flaccid paralysis and coma. Some people experience convulsions, cardiac arrest or local tissue damage. Two sub-species known to cause such necrosis are N. naja ssp. kaouthia and N. naja ssp. leucodira [the Malayan cobra] (Russell 1983). However, with a lethal dose of venom, symptoms may be perceived from as little as 8 minutes after the bite (Deoras 1971). Heating a solution of cobra venom at 90°C for 30min. destroyed the cardiotoxic, haemolytic, and cholinesterase activity, without affecting the neurotoxicity (Devi 1968). In vitro, the neurotoxin could be markedly inactivated by application of sodium bisulfite, zinc, hydrochloric acid, ascorbic acid or cysteine (Ghosh & Chaudhuri 1968).

Naja naja is a slender snake with smooth scales, up to 2m long; varying from black or dark brown above, pale underneath, sometimes with black bands underneath; the typical variety [N. naja naja] is patterned with white spots and spectacles on the hood. Indian cobras are known for their ability to raise the body and spread their hood when threatened. They range through India to Sri Lanka and Pakistan, and there are many subspecies of N. naja in Asia. They shelter in a wide array of habitats, often near human habitation, though serious bites from cobras are rare. They feed on rodents and a variety of other small creatures (Mattison 1995; Mehrtens 1987).

NANANTHUS [including Rabiea]

(Aizoaceae/Mesembryanthemaceae)



Nananthus albinotus *(Haw.) L. Bol.* **(Aloinopsis albinota** *(Haw.) Schwant.***; Mesembryanthemum albinotum** *Haw.***; Rabiea albinota** *(Haw.) N.E. Br.***)** – s-keng keng

Nananthus aloides *(Haw.) Schwant.* **(N. aloides** *(Haw.) N.E. Br.***; Aloinopsis aloides** *(Haw.) Schwant.***; Mesembryanthemum aloides** *Haw.***)**

Nananthus difformis *L. Bol.* **(Rabiea difforme** *(L. Bol.) L. Bol.***)** – 'lizard keng'

'S-keng keng', N. albinotus, is said to be used by Griqua tribesmen of S. Africa as an intoxicant. They pulverise the whole, dried plant before adding it to their tobacco [see **Nicotiana**], either for smoking or snuffing – this addition is claimed to have powerful 'hallucinogenic' effects (Emboden 1979a). N. wilmaniae is known as a 'moervygie' or 'yeast mesemb', and may have been used in brewing 'khadi' mead [see **Delosperma**, *Methods of Ingestion*] (Hargreaves 1999). The root of N. aloides is edible, and is eaten by humans (Watt & Breyer-Brandwijk 1962).

N. difformis has been the subject of only a single human bioassay, that I am aware of. The psychonaut harvested 30g of the plant, 1 month after breaking dormancy, which was crushed in fruit juice and filtered. The consumed extract was reported to cause a degree of MAO-inhibition against *DMT*. The herb was also claimed to have yielded less than 1% of a "mixed harmala alkaloid hydrochloride". Further experimentation was hindered by lack of plant material (pers. comm.).

Chemistry of this genus is relatively unknown, except for independent TLC screening of several species [N. albinotus, N. aloides, N. aff. broomii, N. transvaalensis and Rabiea albipunctata (N. albipunctus)]. No alkaloids were detected, except in N. aloides harvested early Nov. [northern hemisphere], which showed faint bands for *DMT* and 2 other compounds (Trout ed. 1997a; Trout & Friends 1999).

Nananthus albinotus is a dwarf, caespitose, stemless succulent herb with fleshy rhizomes divided apically into short branches. Leaves 6-8, opposite, in dense rosettes, united basally, ascending to spreading, enclosing the internodes, often roughened by raised white or greenish flecky dots, greyish-green, to 3(-10) x 1cm, sabre-shaped, narrowed to an acute, recurved-mucronate apex, upper side flat, lower side rounded basally, keeled and laterally compressed apically, keel abruptly rounded to tip. Flowers solitary, nearly sessile, to (30-)38mm across; calyx 5-lobed, unequally or nearly equally; petals yellow, many, in 3-4 series; stamens many, in an erect columnar mass. Ovary inferior, 9-10 celled; stigmas 9-10. Fruit a capsule, expanding keels broadly winged, placental tubercles absent.

Dry open places; Cape Province, S. Africa [Cradock, Graaff Reinet, Middelburg].

Most growth occurs in summer. In cultivation, they require very tall or tubular pots with a sandy, stony, loamy soil (Bailey & Bailey 1976; Jacobsen 1960).

NARCISSUS

(Amaryllidaceae)

Narcissus jonquilla *L.* – jonquil, narcissus

Narcissus pallidulus *Graells* **(N. triandrus** *L. non Curt***)**

Narcissus poeticus *L.* **(N. pseudopoeticus** *Boutigny***)** – daffodil, poet's narcissus, narcissus

Narcissus pseudonarcissus *L.* **(N. cernuus** *Roth. non Bourg., non Salisb.***)** – King Alfred daffodil

Narcissus tazetta *L.* – buttercup narcissus

Narcissus spp. – daffodil

'Narcissus' is thought to derive from the Greek 'narkê' ['numbness' or 'torpor' – also the origin of the word 'narcotic'], due to the narcotic properties of the herbs (Liddell & Scott 1968). According to Greek legend, Narcissus was a young man who fell in love with his own reflection in the water, and died of unrequited love; narcissus plants grew where he died. To the Greeks, the daffodil represented death, and they planted it near their graveyards (Lawless 1994). It is thought that Persephone was picking daffodils [as 'narkissos'] when she was abducted by Hades, and it has been suggested that the bulb may have been the psychotropic agent used at the Lesser Mysteries of Eleusis [see **Claviceps**, **Amanita**, **Panaeolus**, **Pancratium**], which were associated with that mythical abduction (Samorini 2001). The Arabs considered Narcissus spp. to be aphrodisiac, and in a similar vein, some modern magicians use it to affect fertility. Along with oils of rose, sandalwood [see **Santalum**] and jasmine [see **Jasminum**], 'narcissus oil' is used to anoint the body before prayer in India. Also, the flowers were once used in France as an antispasmodic to treat hysteria and epilepsy (Cunningham 1994; Lawless 1994). N. tazetta bulbs have been taken in brandy as an aphrodisiac. This preparation was used with caution, due to its potency and toxicity (Duke 1983).

Narcissus oil, usually obtained from N. poeticus, but sometimes from other species, blends well with clove [see **Syzygium**], sandalwood, and ylang-ylang [see **Cananga**] essential oils. On its own, the scent is said to be aphrodisiac, hallucinogenic, hypnotic, 'inspiring', narcotic and sedating. One of the predominant effects has been described as a "heavy, dull sensation in the head". It should be used in moderation, as too much can cause headache and nausea (Lawless 1994). I received a report from an individual who ate 'several small pieces' of a daffodil bulb, and reported later feeling "like a flower", before being sick (Wonderfeel pers. comm.). There have been several reports of people consuming daffodil bulbs, mistaken for onions. Symptoms often develop rapidly after consumption, with vomiting, stomach cramps, lightheadedness, shivering, and sometimes diarrhoea. In all reports of human poisoning, there has been complete recovery after c.3 hrs – though this may not necessarily mean that higher doses could not be fatal. The aerial parts are less toxic than the bulbs, though they may cause a type of contact-dermatitis known as 'lily rash' (Litovitz & Fahey 1982).

Most horticultural daffodils are hybrids these days, but most probably have similar effects. The alkaloids found in some species, such as *galanthamine*, are known to strongly affect the cholinergic system by inhibiting AChE (Vasilenko & Tonkopii 1975).

N. bugei floral fragrance yielded mainly [54.7-64.4%] trans-β-oci-

mene, also containing *estragole* [3-3.8%], *methyleugenol* [0.2%], 1,3-dimethoxy-5-methylbenzene [11.4-25.9%], 1,4-dimethoxy-benzene [0-0.8%] and other compounds.

N. jonquilla floral fragrance has yielded 37.2-55.5% methylbenzoate, 0.8-2.1% benzylbenzoate, 1.6-3.9% methylcinnamate, 0.1-0.4% indole, 24.6-26.6% trans-β-ocimene and other compounds (Dobson et al. 1997).

N. pallidulus yielded traces [0.00313%] of the *mesembrine*-alkaloid mesembrenone [see **Sceletium**]; similar alkaloids have only rarely been found outside of the Aizoaceae. Others in the Amaryllidaceae of note are Crinum oliganthum, containing mesembrenol, and Hymenocallis arenicola, containing amisine (Bastida et al. 1989); H. americana leaf has yielded 0.0336% [w/w] *tyramine* (Wheaton & Stewart 1970).

N. poeticus has yielded astragalin, astragalin monobenzoate, lycorine [narcissine, galanthidine – toxic], *galanthamine*, galanthine, homolycorine, lycorenine, narcissidine, oduline, pancrasine, poetamine, poetaminine, poetaricine, poeticine, poetinatine, populin, narcimarkine and piscidic acid (Buckingham et al. ed. 1994; Martin 1987).

N. pseudonarcissus has yielded 0.026% *galanthamine*, lycorenine, 0.013% homolycorine, 0.002% 8-O-demethylhomolycorine, crinine, 0.001% narcidine, 0.005% narcissidine, 0.146% haemanthamine and 0.08% hippeastrine (Tojo 1991).

N. tazetta has yielded *galanthamine*, epigalanthamine, lycorine, homolycorine, pseudolycorine, des-methylhomolycorine, lycoramine, lycorenine, maritidine, O-methylmaritidine, tazettine, pretazettine, haemanthidine, pluviine and epipapyramine (Martin 1987).

Narcissus cultivars were screened for *galanthamine* content – yields averaged 0.005% ['Cheerfulness'], 0.007% ['Geranium'], 0.05% ['Mount Hood'] and 0.065% ['Ice follies'] (Moraes-Cerdeira et al. 1997b). 'Ice follies' was also analysed in more detail – alkaloid content was 0.197% in inner bulb scales, 0.148% in outer bulb scales, 0.461% in bulb basal plates, 0.224% in flowers, 0.259% in bulbils and 0.455% in leaves. Galanthamine was the dominant alkaloid [except in leaves and flowers, where it was overtaken by haemanthamine]; other alkaloids included lycorine, lycoramine, N-demethyllycoramine, caranine and hippeastrine (Moraes-Cerdeira et al. 1997a).

Narcissus poeticus is a glabrous, bulbous, scapose perennial herb; bulb 17-40 x 12-35mm. Leaves all basal, linear to lorate or oblanceolate, often distichous, 20-40cm x 5-13mm, flat, +- glaucous; scape 20-50cm, compressed. Spathe 30-50mm, scarious; pedicel 10-45mm; flowers fragrant, hermaphrodite, regular or slightly zygomorphic, solitary or in umbels of 2-15, subtended by a spathe of 1 usually scarious valve; bracteoles small or absent; hypanthial tube 20-30mm; perianth of 6 petaloid segments, arising from apex of ovary, or from hypanthial tube; segments 15-30 x 6-22mm, ovate, orbicular to oblanceolate-cuneate, white or pale cream; corona free from stamens, 1-2.5 x 8-14mm, discoid to very shortly cylindrical, yellow, with red or scarious margin, crenulate; stamens 6. Ovary inferior, 3-locular; stigma capitate or shortly 3-lobed. Fruit a capsule, ellipsoid to subglobose, pericarp dry. Fl. Jan.-Jun.

Mountain meadows; from east central France, south to central Spain, s. Italy and n.w. Greece (Tutin et al. ed. 1964-1980).

NELUMBO

(Nymphaeaceae/Nelumbonaceae)

Nelumbo lutea *(Willd.) Pers.* – American lotus

Nelumbo nucifera *Gaertn.* **(N. caspica** *(DC.) Fisch.***; N. komarovii** *Grossh.***; Nelumbium nuciferum** *Gaertn.***; Nelumbium speciosum** *Willd.***; Nymphaea nelumbo** *L.***)** – sacred lotus, Indian lotus, Egyptian lotus, pink water lily, lotus lily, Chinese water lily, aquaie, he ye, lian zi xin, lien zi, oujie, padma, pankaja, kanwal

Nelumbo spp. (Nelumbium spp.) – lotus, water lily [see also **Nymphaea**]

Asian cultures venerate the 'sacred lotus' [N. nucifera] as representing perfection, immortality and enlightenment. The growth habit of the plant is partly productive of these beliefs – the plant grows out of the mud on the river or lake bottom, rising through murky waters to flower in the sun well above water level, reminiscent of the quest towards spiritual perfection, and the ascending of the chakras. Fittingly, lotus flowers with varying numbers of petals are used to represent each of the 7 chakras. In India, the flower represents the feminine aspect of creation (Rätsch 1992). Recently, it has been stated to be the definitive identity of 'soma' [see **Amanita**] (McDonald 2004), though no doubt not everyone will agree.

In Ayurveda, N. nucifera seeds are considered aphrodisiac, body-strengthening, cardiotonic, sedative to the uterus, and astringent; they may be useful to allay vomiting and relieve burning sensations in the body. The anthers have similar properties, and the flower is considered good for the eyes, fever and biliousness, allaying coughs, thirst, skin eruptions and poisoning symptoms. Other plant parts again have similar uses in general, but varying from district to district. The leaves have been reported to be used as an antidote to poisonous fungi in east and south-east Asia. In China and Malaya, the rhizome fibre is used to restore health to those with nervous exhaustion (Kirtikar & Basu 1980; Nadkarni 1976; Perry & Metzger 1980); also in China, the leaves have been smoked with tobacco [see **Nicotiana**] (Cooke 1860). In China, the rhizomes are used as an arrowroot substitute in cooking, called 'oce fun', which is known to 'increase mental faculties and quiet the spirits' (Mukherjee et al. 1996).

All parts of the lotus are valued in TCM, particularly as a tonic. The rhizome, seeds and leaf are believed to slow the ageing process. The leaves, which are sometimes used to wrap foods for baking, act as a smooth muscle relaxant, antipyretic and refrigerant, treating symptoms associated with excessive summer heat, as well as stimulating the immune system and increasing vital energy. The stamens have been used to perfume tea [see **Camellia**], and treat premature ejaculation; flowers, filaments and stalk juice are astringent and heart tonic; roots are astringent and haemostatic, treating nausea, acne and eczema. The seeds are used for their antipsychotic, antihypertensive, tranquillising, tonic, aphrodisiac, nervine, antefebrile, antipyretic and cardiotonic activities, and are said to have an affinity for the spleen, kidneys and heart. They are usually taken in a decoction of 6-12g, but should not be used in the event of constipation, indigestion or abdominal bloating (Bremness 1994; Huang 1993; Nishibe et al. 1986; Reid 1995).

In s.e. Asia, the seeds are eaten raw, boiled or roasted, and the rhizome eaten as a vegetable or candied. In n. Australia, indigenous people eat the leaf stalks after stripping the tough outer layer, as well as eating seeds and rhizomes [see also **Nymphaea**] (Cribb & Cribb 1987).

Modern-day psychonauts have noted the seeds of N. nucifera to have +- narcotic properties (Ott 1993). The dried embryo seedlings, or 'plumules' ['lian xin' or 'lian zi xin' in Pinyin Chinese, 'nhuy sen khô' in Vietnamese] also have strong effects, and can be potentiated with small amounts of alcohol [eg. 1 fluid ounce of vodka]. Besides being taken orally, they have been smoked by the 'hot-knife' method [see *Methods of Ingestion*, **Cannabis**] for a "powerful narcotic effect", the smoke having a bitter, alkaloidal taste (theobromus pers. comm.).

The flowers of N. nucifera also have interesting psychtotropic properties, and some believe they may have been the 'lotus' eaten by the 'lotophagi' [as well as Odysseus and his men] in Homer's Odyssey [see also **Nymphaea**, **Ziziphus**; not to be confused with Lotus spp. – see *Endnotes*]. One psychonaut smoked a cigarette of the dried and crushed flowers, and described the effects as consisting primarily of pleasant euphoria, with clarity of thought, and strong apathy for the duration of the effects [up to 4 hours]. The effects had some similarity to those from smoked **Nymphaea** caerulea flowers, though less potent. Smoking another cigarette of the flowers shortly after the first had taken effect did not lead to a noticeable increase in the strength of the effects. Smoking the flowers in equal quantity with **Cannabis** led to profound euphoria and contentedness, with minor changes in visual perception, though the apathetic tendencies were more pronounced, and accompanied by feelings of inertia. This strong inertia was not noted by the same subject when smoking the lotus flowers alone, nor when smoking **Cannabis** mixed with **Nymphaea** caerulea flowers in the same manner. Smoking **Cannabis** near the end of a lotus flower experience enhanced the lingering effects of the lotus, but the inertia described previously did not eventuate; interestingly, the **Cannabis** smoked at this time did not seem to add its own signature to the subjective effects. The flowers may also be infused in wine [7g of flowers per bottle; see *Methods of Ingestion*] or soaked in cranberry juice extracts [1g of 5x extract per cup of juice] to be drunk, as with **Nymphaea** (Jones 2001, 2002).

N. lutea leaves and stems have yielded *nuciferine*, N-nornuciferine, armepavine and N-norarmepavine; petioles have yielded these alkaloids as well as N-methylasimilobine, anonaine and roemerine [see **Roemeria**] (Zelenski 1977).

N. nucifera seeds have yielded a variety of isoquinoline-type alkaloids – *nuciferine*, nornuciferine, pronuciferine, 0.01% armepavine, dl-armepavine oxalate, 0.02% neferine [antihypertensive], lotusine, liensinine [antihypertensive], 0.01% isoliensinine, roemerine, anonaine, demethylcoclaurine, 4'-methyl-N-methylcoclaurine, methylcorypalline and 5-MeO-6-OH-aporphine. Leaves have yielded *nuciferine*, nornuciferine, N-nornuciferine, pronuciferine, dehydronuciferine, anonaine, dehydroanonaine, 0.0015% asimilobine [*serotonin* receptor antagonist], N-methylasimilobine, 0.0022% liriniditie [*serotonin* receptor antagonist], liriodenine, roemerine, dehydroroemerine, armepavine, N-norarmepavine, N-methylcoclaurine, N-methylisococlaurine, 5-MeO-6-OH-aporphine and 0.1% nelumboside [quercetin-3-glucoglucuronide]. Roots contain raffinose and stachyose (Huang 1993; Kunitomo et al. 1973; Lassak & McCarthy 1990; Nishibe et al. 1986; Rastogi & Mehrotra ed. 1990-1993; Shoji et al. 1987). The genus also yields catechol tannins and flavonoids (Schultes & Raffauf 1990). A methanol rhizome extract was shown to have CNS-depressant or narcotic and muscle relaxant activity in mice (Mukherjee et al. 1996).

Nelumbo nucifera is a large aquatic herb with slender, elongate, branched, creeping stems sending out roots at the nodes; juice milky; rhizome horizontal. Leaves membranous, 30-60cm or more diam., orbicular, concave or cupped, erect, exactly peltate, entire, radiately nerved, glaucous, glabrous, much raised out of water; petioles very long, rough

with small distant prickles, otherwise smooth. Flowers solitary, 10-25cm diam., white or rosy; peduncles coming off from the stem nodes, sheathing at base; sepals small, 4-5, inserted on top of scape, caducous; petals many, 5-12.5cm long, elliptic, obtuse, finely veined, concave, at first erect, afterwards spreading, hypogynous, many-seriate, caducous; anthers with a clavate appendage; stamens numerous. Ovaries many, 1-celled, sunk in the flat top of an obconic fleshy torus; ovules 1-2, pendulous; torus 18mm high, spongy, the top flat, 2.5cm across, becoming enlarged in fruit to 5-10cm across; style very short, exserted; stigmas terminal, subdilated. Carpels ovoid, loose in the cavities of the torus, 12mm long when ripe, ovoid, glabrous; pericarp bony, smooth; seed filling the carpel, testa spongy, cotyledons thick and fleshy, enclosing the large folded plumule.

Throughout warmer parts of India; also distributed from Iran east to Australia (Kirtikar & Basu 1980).

NEOTATEA

(Bonnetiaceae/Theaceae)

Neotatea colombiana *Maguire, sp. nov.* – ma-nê-tê'-mee
Neotatea sp.

N. colombiana is used by Taiwano shamans of Amazonia, who dry and powder the flowers, and consume them for divination in unspecified ways [probably snuffed]. They also make use of an unidentified Neotatea sp. in diagnosis, snuffing the dried, pulverised flowers, which have a pleasant fragrance. This latter unidentified species is used by Kubeo shamans in some ritual practices, and is said to possess special powers. Their chemistry is unknown (Schultes & Raffauf 1990).

Neotatea colombiana is a small tree 2-7m tall; branches smooth, glabrous, whitish; terminal bark of branchlets red, dry, papery; wood brittle. Leaves glabrous, sessile, crowded, oblanceolate, usually 6-12 x 2.5-3.5cm, inaequilateral, apex rounded-obtuse, or slightly acute, somewhat subretuse, midrib prominent, lateral veins numerous, c.45° to midrib, parallel and ascending, 0.2-0.4mm apart. Flowers solitary; peduncle usually 18-22mm long, thick, glabrous, 2-3mm diam.; bracteoles soon falling, subtending; sepals 5, imbricate, elliptic-lanceolate, obtuse, 25-30mm long, externally c.20mm wide, internally c.15mm wide, glabrous; petals cordate-flabellate; stamens numerous, filaments free; anthers introrse, linear, basifixed. Ovary 3-locular, placentation subparietal-axillary; style terete, geniculate at base; stigmas 3. Fruit a conical capsule 22-25mm long, c.10mm wide, septicidal, endocarp a separate, solid cartilage; placentation subparietal-subaxillary; funicle descending; seeds numerous, reflexed, winged, 4-5mm long, c.1mm wide, covered with rough reddish hairs, lacking albumen; embryo erect, c.2.5mm long, cotyledons 2, c.1mm long, oblong-rotundate.

Colombia (Maguire et al. 1972).

NEPETA

(Labiatae/Lamiaceae)

Nepeta cataria *L.* **(N. bodinieri** *Vaniot***; Calamintha albiflora** *Vaniot***)** – catnip, catnep, catmint, nepeta, cat's wort, field balm
Nepeta cataria var. citriodora *Becker* **(N. citriodora** *Becker***)**
Nepeta elliptica *Royle ex Bentham*
Nepeta x faassenii *Bergmans* **(N. racemosa x nepetella** *L.***)** – Faassen's catmint
Nepeta grandiflora *Bieb.*
Nepeta hindostana *(Roth) Haines*
Nepeta leucophylla *Bentham*
Nepeta longibracteata *Benth.* **(Glechoma longibracteata** *(Benth.) Kuntze***)** – behungu
Nepeta nepetella *L.* **(N. lanceolata** *Lam.***)**
Nepeta racemosa *L.* **(N. mussinii** *Spreng.***)** – catmint
Nepeta sibthorpii *Bentham*
Nepeta spp.

'Catnip', N. cataria, is a common medicinal herb, with the notable ability to intoxicate cats and other felines merely by aroma, yet as the cats become more interested, they may also eat the herb. Apparently, the plant does not affect all cats of a given species, or felines under 3 months of age. Effects in cats usually last about 15 minutes; Nepeta spp. known to cause these effects so far are N. cataria, N. x faasenii, N. nepetella and N. sibthorpii (Tucker & Tucker 1988).

In ancient Rome, catnip was cultivated, and held in higher esteem than today; it was used as a food seasoning, medicine, and relaxing smoking herb (Bremness 1988). In other parts of Europe, catnip was brewed as tea, before 'real' tea [see **Camellia**] was imported from China (Bremness 1994).

The Cherokee of N. America use N. cataria [an introduced plant] as a stimulant, in the form of a leaf infusion (Hamel & Chiltoskey 1975). The Winnebago give a sweetened infusion of it to babies, to stop them crying and help them sleep. Root and leaf have been used to repel rats and flea beetles; leaves have also been used to flavour meat, or added to salads, and make a good poultice for bruises. An infusion promotes sweating, and is used to treat colds, flu, fever, headache and scalp irritation; it restores menstrual flow, relieves coughs, reduces flatulence and diarrhoea, and acts as a sedative antispasmodic. It has also been given as an enema to cleanse and heal the lower intestine. The leaves may also be chewed to treat toothache (Bremness 1994; Chiej 1984; Kindscher & Hurlburt 1998; Mabey et al. ed. 1990).

In Ladakh, India, N. longibracteata leaves are used "in worship", and leaves and young twigs of N. glutinosa are fed to goats to make them strong (Bhattacharyya 1991). N. elliptica and N. hindostana are ingredients of Ayurvedic preparations for treating epilepsy (Ott 1993).

Since at least the late 1960's, westerners have been occasionally known to experiment with smoking catnip [more rarely made into a tea], usually N. cataria, as a **Cannabis**-substitute. Often the leaves [sometimes flowers too] are smoked in a cigarette or water pipe, or an extract [sometimes available from pet stores] is sprayed on tobacco [see **Nicotiana**], which is then smoked. Effects are sometimes perceived as euphoric and mildly 'hallucinogenic' (Gottlieb 1992; Jackson & Reed 1969; Siegel 1976). These effects are often only experienced with good quality, relatively fresh samples, and the euphoria can be quite intense and pleasant; some people do not seem to perceive the effects. More often, particularly with material purchased from pet stores, catnip may be milder than the above, and produce only relaxation and mild feelings of well-being, or even no effects at all. Herbalists or health stores usually offer fresher, more potent catnip if sold in bulk or in clear packages. Avoid buying catnip [or any other herb, for that matter] which is packaged in a way that its quality can not be inspected. Better yet, grow your own! I have also tested N. x faassenii by smoking, and found it to be more potent than N. cataria. In both cases, flowers seem to be more potent than leaves (pers. exp.).

The psychoactive components of Nepeta spp. are primarily nepetalic acid, *nepetalactone*, and related lactones – these are generally concentrated in the trichomes (Hallahan et al. 1998; Harney et al. 1974, 1977; Tucker & Tucker 1988).

N. caesaria essential oil has yielded mostly 4aα,7α,7aα-*nepetalactone* [opioid-analgesic activity], as well as nepetalic acid, nepetonic acid, 1,5,9-epideoxyloganic acid, and 4 new dihydro-*nepetalactone* derivatives (Topçu et al. 2000).

N. cataria essential oil may contain 70-99.9% cis-trans-*nepetalactone* [*nepetalactone*] and 0.1-30% trans-cis-*nepetalactone* [iso-*nepetalactone*, epi-*nepetalactone*], as well as dihydro-*nepetalactone*, isodihydro-*nepetalactone*, neo-*nepetalactone*, 5,9-dehydro-*nepetalactone*, *eugenol* (Sakan et al. 1965; Tucker & Tucker 1988), thymol, geraniol, and carvacrol (Mabey et al. ed. 1990); nepetariaside has also been found (Murai et al. 1987).

N. cataria var. citriodora essential oil yielded 12.2% of a mixture of *nepetalactone*, iso-*nepetalactone* and dihydro-*nepetalactone* (Tucker & Tucker 1988).

N. grandiflora, collected in flower, yielded 0.18-0.31% essential oil from wild plants, consisting of 33.5% *nepetalactone*, 16.1% epi-*nepetalactone*, 13.5% pulegone, 6.3% terpineol, 3.8% *thujone*, 3.6% α-*pinene*, 0.8% β-*pinene*, 1.9% cineol, 0.9% menthone, 0.6% cymol, 0.4% citronellol, 0.4% *borneol*, and traces of isomethane; seed-grown plants in cultivation yielded 0.12-0.14% essential oil (Mishurova & Malinovskaya 1989).

N. hindostana essential oil has yielded 7.5% *nepetalactone*.

N. leucophylla essential oil has yielded 3% *nepetalactone*.

N. nepetella essential oil has yielded 76.5% *nepetalactone*, 0.6% iso-*nepetalactone*, 1.6% dihydro-*nepetalactone*, 0.4% neo-*nepetalactone* and traces of 5,9-dehydro-*nepetalactone* (Tucker & Tucker 1988).

N. racemosa essential oil may contain 16.7% *nepetalactone* and 70% cis-cis-*nepetalactone*, as well as iso-*nepetalactone* (Hallahan et al. 1998; Tucker & Tucker 1988).

Nepeta cataria is a strongly aromatic perennial herb; stems erect, much-branched, to 2m tall (usually less), finely pubescent. Leaves opposite, narrowly to broadly deltoid, 3-8cm long, coarsely crenate-dentate, truncate or subcordate at base, upper surface grey-green, lower surface paler and downy; petioles ½ as long as leaf blade. Flowers in whorled clusters from tips and leaf axils, 2-6cm long; calyx 5-toothed, 7mm long, lobes c.½ as long as tube; corolla tubular, 10-12mm long, with 2 lobes, upper bilobate, lower trilobate, dull white, lower lobe dotted with pink-purple. Gather late spring, when coming into flower.

Mountainous regions of Europe, in Britain by roadsides, hedgerows and streams; native to s.e. Europe and s.w. Asia, grows as a weed in North America (Chiej 1984; Gleason 1952). Easy to cultivate, but requires regular watering, and protection from excessive full sun. Care should be taken where it is grown, as the plant has great weedy potential due to vigorously spreading rhizomes (pers. obs.).

NEPHELIUM

(Sapindaceae)

Nephelium juglandifolium *Bl.* **(N. altissimum** *Teijs. et Binn.***)**
Nephelium topengii *(Merr.) Lo* **(Xerospermum topengii** *Merrill***)** – shan li chi, lung-li

N. topengii is thought to be referable to 'lung-li', mentioned in ancient Chinese herbal texts as having hallucinogenic properties. Its fruit, the flesh of which tastes like 'longan' [N. longana] fruits and has a sweet, hot nature, may only be eaten after steaming. If eaten raw, it is said to cause one to "go mad or see devils" (Li 1978). The pulp of N. litchi [Litchi chinensis; 'litchi' or 'lychee' tree] fruit is used in India to quench thirst in fever; it is said to be aphrodisiac (Nadkarni 1976). In China, N. litchi seeds are used to treat neuralgia; in TCM they are powdered and taken in a dose of 4-7g as an analgesic and astringent. N. longana arils are also used in TCM [dose – 10-15g] as a nutrient tonic to treat neuraesthenia and insomnia. The seeds of the Malaysian N. juglandifolium are known to be narcotic (Keys 1976; Perry & Metzger 1980).

Chemistry is obscure, though seeds of some species are known to contain saponins, tannins, sugars and vitamins (Keys 1976; Perry & Metzger 1980).

Nephelium topengii is a tree c.10m tall, subglabrous; branches terete, glabrous, branchlets puberulous. Leaves spirally arranged, 20-25cm long, 5-foliate; leaflets oblong-lanceolate, chartaceous, 10-15 x 3-4cm, acuminate, base acute, mostly unequal, upper side olive-green, glabrous, nitid, underside pallid, subglaucescent, lightly pubescent, hairs beneath appressed, nerves on both sides c.14, on underside conspicuous, reticulation on both sides distinct. Inflorescence paniculate, terminal and axillary, under fruit 10-12cm long, +- pubescent; flowers actinomorphic; calyx thick-fleshy, lobes 4-6, segments valvate, rounded or obtuse; petals 4-6 [or none], without appendages at base; stamens or staminodes 5-8, hairy. Disc usually glabrous; ovary densely pubescent, in female deeply 2-3-lobed, lobes 1-celled; cells 1-ovuled; style 2-3-branched. Fruit ellipsoid, 2-2.5cm long, rotundate, when dry dark chestnut brown, densely-tuberculate/knobbly, muricate, processes rigid, 2.5-3.5mm long, straight or slightly curved, obtuse or truncate, sulcate, 0.5-1mm across, base pyramid-shaped.

China, on forested slopes (Backer & Bakhuizen van den Brink 1965; Merrill 1923).

NICOTIANA

(Solanaceae)

NICOTIANA TABACUM

Nicotiana attenuata *Torrey* – mountain tobacco, dzil nat'oh
Nicotiana benthamiana *Domin.* **(N. suaveolens var. cordifolia** *Benth.***)** – anterlp, irranerratye, mara-kanyala, tjuntiwari, wanngati, multu, yarrampa, ingulba pudura
Nicotiana bigelovii *(Torrey) Watson*
Nicotiana cavicola *Burbidge* – talara, pinkaraangu
Nicotiana debneyi *Domin.* **(N. suaveolens var. debneyi** *Bail.***)**
Nicotiana excelsior *J. Black* **(N. suaveolens var. excelsior** *J. Black***; N. macrocalyx** *Domin.***)** – atnwengk, pitwerre, piturr, piturrba, warrngati, pulyantu, ukiri, wanngati, pulandu, inkulba, mingul, mingulba, carmen
Nicotiana glauca *Graham* – tree tobacco, me-he-kek, mingkulpa, mulapa
Nicotiana glutinosa *L.*
Nicotiana goodspeedii *H. Wheeler*
Nicotiana gossei *Domin* – rock pituri, ngkwerlp-rnpernp, rnpwernp, tjunpumpa, piturr, piturpa, jurnpurnpa, jurnpurrnpu, ingulba inbinba, ingulba, engulba, mingul, mingulba, ngulba
Nicotiana ingulba *J. Black* **(N. rosulata ssp. ingulba** *(J. Black) P. Horton***)** – sandhill pituri, ingulba ngunjiga, ngkwerlp-atherrk, arwernp, atnengkwe, pitwerre, manakarrata, tjurratja, anultja, talyunganu, tawal-tawalpa, yarunpa
Nicotiana macrophylla *Spreng.* **(N. latissima** *Mill.***)** – Maryland tobacco, broad-leaf tobacco
Nicotiana megalosiphon *Heurk et F. Muell.* **(N. suaveolens var. longiflora** *Benth.***)** – ingulba ndurilba
Nicotiana paniculata *L.* – tabaco cimarrón
Nicotiana quadrivalvis *Pursh* – four-valved tobacco
Nicotiana rustica *L.* – Turkish tobacco, English tobacco, East India tobacco, Indian tobacco, yellow-flowered tobacco, picietl, tabaco moro, oyengwe onwe ['real tobacco'], wipaka, makuchi, wiparu, wipanto
Nicotiana simulans *Burbidge* – tjanyungu, tjungarayi tjungarayi
Nicotiana suaveolens *Lehmann* **(N. exigua** *H. Wheeler***; N. undulata** *Vent.***)** – ingulbingulba, mingul-mingulba, ngulbingulba, pinna-pinna
Nicotiana sylvestris *Speg. et Comes*
Nicotiana tabacum *L.* – American tobacco, Virginia tobacco, tabaco blanco, bujjir bhang, tamaku, quauhyetl, wipaka, makuchi, tsaank, tsang, tsaan
Nicotiana trigonophylla *Dunal ex DC.* – desert tobacco, wild tobacco, coyote's tobacco, bawaráka, wipaka, ban vivga
Nicotiana velutina *Wheeler* – ingulba ndurilba
Nicotiana spp. – tobacco

Tobacco is one of the world's most widely used drugs, and has been used for centuries in many forms – chewing, drinking, snuffing and smoking are the usual approaches to its ingestion. It is considered the prime entheogen by many shamans of N. & S. America, which seems odd to those of us accustomed to weak commercial tobaccos. The types used shamanically are generally much richer in *nicotine* content, so much so that those not used to it can not take more than one inhalation of the acrid, pungent smoke. Since the Spanish conquest and discovery of tobacco use in the Caribbean, tobacco spread and was adopted by shamans and others almost worldwide, especially in s.e. Asia (Ott 1993; Pendell 1995; Rätsch 1992; Von Bibra 1855).

In some parts of Australia, however, the indigenous peoples already used native Nicotiana spp., and thus N. tabacum was only another addition from the 'white man'. The tribes of arid regions, where the tobacco grows [it was not cultivated, though it is in Torres Strait], chewed the dried, crushed leaves with alkaline ash [often from **Acacia** spp.], sometimes bound with animal hair and ochre, as a 'stimulant-narcotic'. Sometimes the flower buds and leaves were chewed fresh. It was often interchanged with 'pituri' [see **Duboisia**], considered by some to be more desirable. Species documented to have been used, in approximate descending order of potency and/or desirability, are N. gossei, N. excelsior, N. benthamiana, N. ingulba, N. cavicola, N. glauca, N. simulans, N. megalosiphon, and N. velutina – these last two species are considered too weak to be worth chewing. Although N. suaveolens is relatively common, it has remained virtually unutilised, apparently due to its low potency (Cribb & Cribb 1981; Johnston & Cleland 1933; Lassak & McCarthy 1990; Latz 1995; Low 1990; O'Connell et al. 1983; Peterson 1979; Thomson 1939).

Native peoples of the Everard Ranges [n. South Australia] and Blyth Ranges [w. South Australia, e. Western Australia] have been noted to use what was probably N. gossei. The leaves were prepared for use by "being almost dried over heated sand [taken from beneath a fire], kneaded into little balls between the teeth in order to give cohesion, then rolled into a mass about the size of the thumb, then dried again and reserved for future use." The prepared drug was used by placing it between the lower lip and the gums, for sucking; the wad was stored behind the ear when eating. In contrast, the Aranda and Luritja have been known to use the whole plant, including roots, which they sun-dry, grind, and mix with alkaline ashes (Johnston & Cleland 1933).

Smoking was believed to have been introduced as a method of consumption only after the arrival of Europeans, though in the Northern Territory, tobacco is often smoked in pipes, apparently a traditional use [probably originating from Papua New Guinea]. Such pipes vary considerably in their construction, some carved from the wood of various plants, others made from leg bones of birds, from marine mollusc shells or from crab pincers, amongst other ingenious innovations. Pipes may be passed ceremonially to establish solidarity or a communal bond; other ornate sacred pipes may only be smoked by fully-initiated members of

a clan (Thomson 1939). A Nicotiana sp. from Port Hedland [Western Australia], which was probably N. benthamiana, was noted to have been popular amongst local indigenous people for smoking. It "had the effect of making them at first excited, then stupidly heavy, and finally sent them off to sleep". It is worth noting that in many early literature reports, much reference has been made to N. suaveolens. However, previous to 1935, all native Nicotiana spp. in Queensland were known under this name. These include N. debneyi, N. gossei, N. megalosiphon and N. velutina (Johnston & Cleland 1933; Webb 1948). Early white explorers on one occasion reported sampling N. suaveolens when passing through flats near Mt. Flinders, in the Macquarie Ranges. A member of the expedition, Allan Cunningham, noted the dried lower leaves were "not a bad substitute for its congener, N. tabacum, although not so strong a narcotic" (Johnston & Cleland 1933).

The Bimin-Kuskusmin of Papua New Guinea use 'ritual' strains of N. tabacum in stages 4-9 of their initiation, occurring at dusk. The plants are surrounded with ritually sacrificed meat shortly before use. As well as being eaten, tobacco leaves are smoked with deep inhalations through pipes of bamboo [Bambusa sp.; stages 4-6] and pepper [**Piper** sp.; stages 7-9], wrapped in different leaves; other plants are also consumed [see also *Endnotes*] (Poole 1987). The use of N. tabacum as a magical plant is widespread in PNG (Glick 1967; Marshall 1987; Paijmans ed. 1976; Schmid 1991).

Although tobacco was only introduced to India in the 16th century [by the Portuguese], it has attracted reverence from some indigenous groups [though not from Hindus] who have elaborated numerous origin myths for the plant, some of which are described by Mehra (1979). It is often used in casual routine rituals, and as a recreational drug after a hard day's work. Amongst the Muria, asking for a 'puff of tobacco' after marriage is equivalent to asking for sexual intercourse. The Sema Nagas place a pipe and some tobacco in the graves of their deceased warriors, and the Bhil include tobacco in offerings to the dead during funeral rites (Mehra 1979). Chewing tobacco with betel nut [see **Areca**] is a common method of use in India. Tobacco is often smoked in India and Nepal in the form of 'bidi' cigarettes, for which numerous species may be used as wrappers [eg. see **Musa**, and Lyonia and Shorea in *Endnotes*], although bidis may also contain other herbs [eg. see **Datura**] (Müller-Ebeling et al. 2002; Nadkarni 1976).

Tobacco from introduced Nicotiana spp. is widely used recreationally in Africa, often snuffed or held between the lower lip and gums [called 'dipping' in parts of the US], though it is also smoked in pipes. The Xhosa and Mfengu are particularly known for their habitual 'dipping' (De Smet 1998; Watt & Breyer-Brandwijk 1962). Snuffs may take the form of dry powder [mixed with alkaline plant ashes], or a liquid [dried, powdered tobacco leaves mixed with ashes and water]. The liquid snuffs are measured by dose into the cup of the hand and more or less poured into the nostrils with the head tipped back. Special nose clips are often employed to hold the liquid inside the nasal cavities until the user has had enough (De Smet 1998). N. rustica is smoked and snuffed by the Southern Sotho, and it is decocted as an emetic by the Lissongo (Watt & Breyer-Brandwijk 1962). In eastern Africa, the Masai snuff tobacco as a mild euphoriant (Lehmann & Mihalyi 1982). N. glauca, which also grows in the area, has caused poisonings in ostriches, with symptoms including "staggering gait, spasmodic jerkings of the head, dullness and stupor", soon followed by death (Watt & Breyer-Brandwijk 1932). In some parts of Africa, 'juice' from tobacco pipes has been used as a homicidal poison (De Smet 1998).

North and Central American natives smoke tobacco in a ritual sense, and the Navajo, for example, have complex ritualised formats for the making of ritual pipes, which are used for shamanic purposes and at meetings [the 'peace pipe' – see also **Arctostaphylos** and other kinnikinnicks] (Winter 1998). To the Karuk of California, tobacco is a very important substance, and is generally smoked in pipes in the evenings. The cured stems constitute an inferior grade of tobacco, "used by hunters, priests of ceremony, and doctors as offerings to the Ikxarey, the 'old-time' people, who turned into animals, plants, rocks, mountains". Species used in N. America include N. attenuata, N. bigelovii, N. bigelovii var. exaltata, N. quadrivalvis, N. rustica and N. trigonophylla (Furst 1976; Harrington 1932; Winter 1998).

N. rustica was known as 'picietl' to the Aztecs, and the dried, powdered leaves are rubbed on the body for ritual purification, or chewed with lime; they also knew N. tabacum, as 'quauhyetl'. The flowers of the latter have been identified on the statue of the Aztec deity Xochipilli [see **Turbina**]. The Huichol smoke N. rustica as an entheogen, sometimes with **Tagetes** lucida; they also may drink it in the purification stages of the peyote quest [see **Lophophora**]. The Tarahumara smoke cigarettes of N. rustica during night ceremonies; more rarely, they smoke N. trigonophylla. To them, tobacco is more powerful than **Datura**, but is considered less important than peyote. Tobacco was very important to Mayan religion, and is still revered by surviving Mayan groups today (Bye 1979b; Emboden 1979a; Furst 1976; Robicsek 1978; Siegel et al. 1977; Wasson 1963, 1973).

In the Amazon, tobacco [usually N. rustica or N. tabacum] is often only smoked shamanically, in pipes or cigars, and is seen to protect from evil influences; for recreation, it is usually snuffed [with ash of **Theobroma** subincanum, and sometimes with **Capsicum** spp.], and sometimes boiled to a syrup ['ambil', 'ye-rras'] for application to the gums – this is sometimes taken with coca [see **Erythroxylum**]. Such syrups or thick decoctions are sometimes inhaled nasally [as is often done in the San Pedro ceremonies of the Andes – see **Trichocereus**]. The syrup may be prepared in a number of ways – one method is to steep the leaves in water for a long period, later mixing the strained liquid with 'yucca' starch [from Manihot utilissima] and 'sugii' [a Sorghum sp. – see *Endnotes*]. Another method resembles alchemical practices. Large, lower leaves are boiled slowly in a pot for several hours. Salts are prepared from leaves and petioles of a Chamaedorea sp. and young shoots of a Bactris sp. – these are burnt to ash, and water is passed through the ash. This water is evaporated to obtain the salts, which are added to the tobacco extract just before it becomes thick. The Chimila of Colombia chew dried tobacco leaves, which have been pulverised and mixed with a small amount of ash and honey, to form small cakes c.2cm long (Bennett 1992; Davis 1996; Emboden 1979a; Schultes & Raffauf 1990; Uscategui 1959). In Peru, shamans may use a variety of Nicotiana spp. N. rustica is used for curing, and N. tabacum for liquid snuff ['shingada'] made by soaking the leaves in cane alcohol. N. glauca is used for its CNS-stimulant and 'hallucinogenic' properties, and N. paniculata is also known to be a potent species (De Feo 2003).

Shamans of the Guianas have been known to smoke tobacco in large hand-rolled cigars, as well as eating, drinking and snuffing it during initiations. Shaur boys drink the juice from steeped tobacco leaves at the age of 6, to help them find their soul or 'arutam'. Girls also drink it in ceremonies to communicate with spirits governing crop cultivation. Tobacco is often used in the Americas throughout ceremonies centred on the use of another visionary substance [eg. ayahuasca (with which it is commonly brewed, also – see **Banisteriopsis**), **Virola**, **Lophophora**], sometimes in very large amounts which would be toxic to outsiders. Shamans of the Orinoco have been known to smoke 5-6 1m-long cigars in one session – such long cigars often need to be supported by a forked prop! Tobacco shamans are skilled in accurately measuring out dosage, and they need to be, because tobacco is highly toxic and can kill. Shamans and initiates addict themselves to tobacco over long periods [even the gods are said to be addicted to it], until they can master the dose needed to elicit an entheogenic state – this dose is near the lethal dose, and it causes novices to be 'driven out of their minds', go blind, and collapse into a death-like sleep. Initially there is nausea, vomiting, abdominal pain, sweating, salivation, trembling, rapid and irregular heartbeat, high blood pressure, dizziness, confusion, and heavy, laboured breathing, followed by tremors and convulsions, lowered blood pressure, and collapse. If the dose was correct, the participant returns to consciousness after a few hours, once the *nicotine* alkaloids have been metabolised; if not, death due to respiratory paralysis may occur. The whole experience is intended to be a journey towards the realms of dying, where shamanic work is completed, before returning to the world miraculously (Bennett 1992; Davis 1996; Emboden 1979a; Furst 1976; Pendell 1995; Rätsch 1992; Rivier & Lindgren 1972; Robicsek 1978; Schultes 1972; Turner & Szczawinski 1991; Uscategui 1959).

Many shamans in the Amazon eat little 'real' food, consuming tobacco in a variety of ways instead, as it is considered a food that is nourishing to shamans. Tobacco is known to inhibit hunger pangs for up to several hours per administration, as well as raise blood sugar levels and cause *epinephrine*-release [hence the anorexic effects]. Tobacco-shamans ['tabaqueros'] also have 'guttural and dark-timbred singing voices', reputedly an aid to spirit-communication, which is developed and fed with continual tobacco smoking [a 'shamanic voice-box']. Their eyes are also said to be 'special', caused by the pupil-constriction of tobacco-smoking, as well as the optical disorder 'tobacco amblyopia' [dim-vision and colour-blindness, or yellow-tinted vision – also including symptoms such as fatigue, depression, anxiety, insomnia, suppressed appetite for food and sex, constipation and pallid skin], which allows him to see better at night than at daytime, thus becoming a true 'creature of the night' like the jaguar, an animal of great shamanic power. The tobacco also causes decreased skin temperature [due to peripheral vasoconstriction] and analgesia [due to central cholinergic blockade], allowing him to display tolerance to fire and pain. Tobacco smoke is often utilised in healing sessions by blowing it over the patient, or spitting tobacco-juice at afflicted body parts. The former is known to usually calm the patient, and lower their temperature [leading to greater comfort], aiding natural healing processes (Furst 1976; Pendell 1995; Wilbert 1991).

An unusual and dangerous initiation rite has been described by Bear (1997) and Bear & Vasquez (2000). About 200g tobacco is decocted in water and strained; this decoction is placed in a small hollow, carved into a remocaspi tree [see **Aspidosperma** and **Pithecellobium**]. The hole is plugged up with mud, and splinters from the tree, and left for 8 days. After this time, the preparation has fermented, and is inundated with mould-fungi [see **Aspergillus**, **Geotrichum**, **Hypomyces**, **Penicillium**, and **Rhizopus**], which are stirred into the drink before it is consumed. A semi-comatose state soon prevails, during which the initiate experienc-

es visions; this state lasts for 3 days, if the initiate does not die. It is said that if one survives this process, they will be a powerful healer (Bear 1997; Bear & Vasquez 2000).

Tobacco, when smoked in small amounts, is a short-term CNS-excitant and tranquilliser, which can improve cognitive functioning in regular smokers. In higher amounts, or with very potent tobaccos, the effects are more extreme and may range from a brief 'rush' followed by increased heart-rate and core-body temperature, perspiration, nausea and dizziness, lasting only a few minutes, to unconsciousness due to fainting (pers. obs.). Overdose causes symptoms described in the text above. The health risks of smoking tobacco are well known and need not be further discussed here. I will note, however, that *nicotine* is reportedly more addictive than heroin (Byrne 1988)!

In Australia, illicit cheap tobacco known as 'chop-chop' is widely sold under the counter, and many users believe it to be 'organic' and therefore healthier and free of additives. Not only is the supposed organic origin of this tobacco highly suspect, much of it has been reported to be cut with straw, and dampened with water and chlorine bleach, leading to greater deterioration of health in smokers of such products (Robotham 2002). Legal tobacco isn't much better, carrying high levels of pesticide residues as well as numerous unspecified additives used to improve the smoking characteristics of the finished product [although in some countries tobacco companies are required to inform government agencies of additives used in the industry, it is practically unheard of for the actual additives and quantities used to be identified for any particular brand, and although lists of hundreds of additives can be found, any given brand may only use a relatively small number of these]. Contrary to popular opinion, pipe and rolling tobaccos may contain far more additives than the tobacco in pre-rolled cigarettes [10.7-33.4% as opposed to 0.2-0.4%, respectively, in one limited analysis] (Chapman 2003) Most tobacco companies also add ammonia and ammonia-forming compounds to tobacco to increase the *nicotine* impact, as this converts the nicotine from its salt to its free-base form, which is much more volatile [analogous to free-base or 'crack' *cocaine*] (Pankow et al. 1997). Also, as a piece of trivia, studies on the width of tobacco fibers have shown that increased width raises the levels of *nicotine*, tar, and dry condensate in smoke, whilst their accumulation in the cigarette butt decreased. A threshold of 0.8mm width was found, above which little further change was noted (Georgiev 1973).

Smoking tobacco causes [in regular smokers] inhibition of MAO-A [c.28%] and MAO-B [c.40%] in the brain, measured 2.7 hours after smoking. Also, in isolated rat brain, similar inhibition of MAO-A & -B inhibition was shown by cyano-derivatives of 1,2,3,4-tetrahydroisoquinoline [THIQ], which are formed by reaction of brain THIQ with cyanide-compounds found in tobacco smoke (Fowler et al. 1996; Khalil et al. 2000; Mendez-Alvarez et al. 1997). Smoking tobacco increases levels of *harman* and *norharman* from 40-100 times the concentration found in fresh leaves, which is expressed in the smoke [0.00036-0.00058% *harman*, 0.00126-0.00141% *norharman*; one study found 207-2780ng β-carbolines per cigarette] (Herraiz 2004; Poindexter & Carpenter 1962), elevating plasma *norharman*-levels within 5-10 mins, and declining after 1hr (Breyer-Pfaff et al. 1996). Tobacco smoke also contains *harmine* and *harmaline* (Shulgin & Shulgin 1997), which may contribute to reported MAO-A inhibition. As well as *harman* and *norharman* [and many other compounds, largely resulting from chemical additives to commercial tobaccos], *anabasine*, N-methylanabasine, nicotinamide, β-nicotyrine, myosmine, 2,6-dimethylquinoline, pyridine, 2,2'-bipyridyl, hydrocyanic acid [HCN], ammonia, hydrogen sulphide, carbon monoxide and carbon dioxide have been found in cigarette-smoke condensate (Brown & Ahmad 1972; Watt & Breyer-Brandwijk 1962).

Nicotine is found in all parts of the plant, in *nicotine*-dominant species; leaves become more potent towards the apex, and at ripeness; stems contain less than 1/3 the amount of *nicotine* found in leaves; flowers less than 1/3 of that in stems; roots may yield more than twice as much as flowers. *Nicotine* is present in the fresh plant partly as a mixture of the glucosides tabacilin and tabacin [0.4-0.5%]. Tabacilin yields *nicotine* and glucose on hydrolysis; tabacin, when heated to around 110°C, breaks down into tabacol [a powerful convulsant poison], tabacinic acid and a sugar – tabacol yields *nicotine* on protracted heating with potassium hydroxide (Watt & Breyer-Brandwijk 1962).

N. attenuata leaves yielded 2.2269% alkaloids [98.4% *nicotine*, 0.8% each of *nornicotine* and anatabine and traces of *anabasine*]; roots yielded 0.2484% alkaloids [89.8% *nicotine*, 5.2% *nornicotine*, 5% anatabine, traces of *anabasine*].

N. benthamiana leaf has yielded 0.002-0.31% *nornicotine*, 0.29-0.48% *nicotine*, 0.0058% *anabasine* and 0.009% anatabine; roots yielded 0.26% *nicotine*, 0.005% *nornicotine*, 0.1% *anabasine* and 0.015% anatabine (Latz 1995; Saitoh et al. 1985; Webb 1948).

N. bigelovii leaves yielded 0.78% alkaloids [96.8% *nicotine*, 2.3% *nornicotine*, 0.9% anatabine, traces of *anabasine*]; roots yielded 0.22% alkaloids [91.7% *nicotine*, 4.9% *nornicotine*, 3.4% anatabine, traces of *anabasine*] (Saitoh et al. 1985).

N. cavicola leaf yielded 0.0285% alkaloids [76.9% *nornicotine*, 16.8% *nicotine*, 6.3% *anabasine*, traces of anatabine]; roots yielded 0.3798% alkaloids [58% *nicotine*, 25.4% *anabasine*, 9.1% *nornicotine*, 7.5% anatabine].

N. debneyi from e. Australia has yielded 0.113-0.4% *anabasine*, 0.076% *nicotine*, 0.0388% *nornicotine* and 0.0174% anatabine from the leaves; roots yielded 0.105% *nicotine*, 0.16% *anabasine*, 0.004% *nornicotine* and 0.0325% anatabine (Everist 1974; Saitoh et al. 1985; Webb 1948).

N. excelsior leaf has yielded 1.89% alkaloids [95.9% *nicotine*, 1.1% *nornicotine*, 0.9% *anabasine*, 2.1% anatabine]; roots yielded 0.477% alkaloids [66.5% *nicotine*, 1.4% *nornicotine*, 20% *anabasine*, 12.1% anatabine] (Saitoh et al. 1985; Shaw et al. comp. 1959).

N. glauca showed a rise in alkaloids, nitrogen, proteins and citric acid after clipping the tops. Leaf has yielded 0.3-1.3% *anabasine*, 0.11-0.9% *nicotine*, 0.013% *nornicotine*, 0.008% anatabine, 2% rutin, citric acid, oxalic acid, malic acid and succinic acid; roots yielded 0.629-1% *anabasine*, 0.186% *nicotine* [3.6% in fresh root], 0.147% *nornicotine* and 0.054% anatabine (Khmura 1938; Kovalenko 1934; Saitoh et al. 1985; Schermerhorn et al. ed. 1957-1974; Smith 1935; Watt & Breyer-Brandwijk 1962; Webb 1948). The coumarins *scopoletin* and aesculetin are found in the aerial parts [up to 0.00092% w/w] (Kala 1958).

N. glutinosa leaf has yielded 0.9309% alkaloids [90.7% *nornicotine*, 6% *nicotine*, 3% anatabine, 0.3% *anabasine*]; roots yielded 1.467% alkaloids [83% *nicotine*, 10.8% anatabine, 3.2% *nornicotine*, 3% *anabasine*] (Kovalenko 1934; Saitoh et al. 1985).

N. goodspeedii, which is widespread in parts of southern Australia (Haegi et al. 1982), has yielded 0.008% *nicotine* (Shaw et al. comp. 1959).

N. gossei leaf has yielded 0.96-1.2% *nicotine*, with traces of *nornicotine*, *anabasine* and anatabine; roots yielded 0.53% *nicotine*, 0.129% *anabasine*, 0.054% anatabine and 0.0065% *nornicotine* (Latz 1995; Peterson 1979; Saitoh et al. 1985). Earlier the plant was stated to contain "solely *nicotine*", in a yield of 1.1% (Webb 1948).

N. ingulba leaf has yielded 0.0669% alkaloids [44.8% *nornicotine*, 42.2% *anabasine*, 7.5% *nicotine*, 5.5% anatabine]; roots yielded 0.48% alkaloids [46.3% *nicotine*, 42.3% *anabasine*, 4.5% *nornicotine*, 6.9% anatabine].

N. megalosiphon from n.e. and c. Australia has yielded 0.013-0.22% *nornicotine*, 0.0126% *anabasine*, 0.0059% *nicotine* and traces of anatabine in the leaf; roots yielded 0.28% *nicotine*, 0.243% *anabasine*, 0.01% *nornicotine* and 0.022% anatabine (Saitoh et al. 1985; Webb 1948).

N. paniculata leaves yielded 0.71% *nicotine*, 0.13% *nornicotine*, 0.002% *anabasine* and 0.008% anatabine; roots yielded 0.42% *nicotine*, 0.4% *nornicotine*, 0.013% *anabasine* and 0.026% anatabine (Saitoh et al. 1985).

N. rustica leaf has yielded [0.18-]4.5-8.6% *nicotine*, 0.0069-0.48% *nornicotine*, 0.0085% *anabasine*, 0.012% anatabine, 0.66-0.89% rutin, 3.6-11.8% citric acid, *choline* and sucrose; root has yielded 0.688% *nicotine*, 0.014% *nornicotine*, 0.0557% *anabasine* and 0.085% anatabine (Steiner 1932; Watt & Breyer-Brandwijk 1962). The coumarins *scopoletin* and aesculetin are found in the aerial parts, though only *scopoletin* is found in the root [up to 0.001% w/w] (Kala 1958).

N. simulans leaf has yielded 0.0258% alkaloids [67% *nornicotine*, 19% *anabasine*, 14% *nicotine*, traces of anatabine]; roots yielded 0.66% alkaloids [45.1% *nicotine*, 44.3% *anabasine*, 6.4% *nornicotine*, 4.2% anatabine].

N. suaveolens leaf has yielded 0.4954% alkaloids [85% *nicotine*, 13.6% *nornicotine*, 0.9% *anabasine*, 0.5% anatabine]; roots yielded 0.6658% alkaloids [51.7% *nicotine*, 29% *anabasine*, 9.9% *nornicotine*, 9.4% anatabine] (Saitoh et al. 1985; Shaw et al. comp. 1959).

N. sylvestris leaf has yielded 2.96% alkaloids [80% *nicotine*, 19.1% *nornicotine*, 0.7% anatabine, 0.2% *anabasine*]; roots yielded 0.7864% alkaloids [89.9% *nicotine*, 6.3% *nornicotine*, 2.8% anatabine, 1% *anabasine*] (Kovalenko 1934; Saitoh et al. 1985); flowers also yielded rutin and kaempferol-3-rhamnoglucoside (Schermerhorn et al. ed. 1957-1974). *Scopoletin* was found in the leaf [0.0002% w/w] and root [0.0048% w/w] of a young plant (Kala 1958).

N. tabacum may yield c.0.05-2% *nicotine*, sometimes up to 6% or more; as well as 0.05-0.36% *nornicotine*, *anabasine*, N-methylanabasine, piperidine, pyrrolidine, N-methylpyrroline, 3-acetylpyridine, nicotinamide, nicotinic acid, nicotianine, orynicotine, nicoticine, nicotimine, nicotyrine, nicotoine, nicotelline, anatabine, N-methylanatabine, trimethylamine, myosine, *harman* [0.000002-0.00033%], *norharman* [0.000018-0.00123%], *tryptophan* [0.007-0.45% free, 0.3-0.9% protein-bound], *tryptamine* [0.000035% w/w], indoleacetic acid, 0.21% rutin, *chlorogenic acid*, caffeic acid, citric acid, succinic acid, fumaric acid, oxalic acid, malic acid, iso-hexoic acid, phthalic acid, caprylic acid, isoquercetin, isovaleric acid, *eugenol*, *pinene*, butyl alcohol ester, furfural, *glutamic acid*, *GABA*, *aspartic acid*, *glutamine*, asparagine, *scopoletin*, aesculetin, heptacosane, hentriacontane, scafatin, calcium chloride, fructose, pectin, tannin and mucilage (Kala 1958; Poindexter & Carpenter 1962; Schermerhorn et al. ed. 1957-1974; Schneider et al. 1972; Shaw et al. comp. 1959; Watt & Breyer-Brandwijk 1962). *Nicotine* content of the flower [of N. tabacum] in one test was as follows – flower axis 0.0254%, calyx 0.1435%, petal 0.0086%, ovary base 0.0156%, ovary 0.008%, stamen 0.0014% and stigma/style 0.0014%. Capsules of N. tabacum also yielded small amounts of *nicotine*; the calyx of immature capsules yielded 0.6% *nicotine*, as well as 0.0024%

nornicotine and 0.0015% *anabasine*, whilst the mature capsule calyx yielded only 0.26% *nicotine*. Seeds also contain traces of *nicotine*, possibly due to contamination from plant material (Saitoh et al. 1985).

N. trigonophylla leaf yielded 0.11% alkaloids [94.9% *nornicotine*, 3.3% anatabine, 1.8% *nicotine*, traces of *anabasine*]; roots yielded 1.4458% alkaloids [55.8% *nicotine*, 38.2% *nornicotine*, 5.6% anatabine, 0.4% *anabasine*] (Saitoh et al. 1985).

N. velutina from central Australia yielded 0.5276% alkaloids from the leaf [88.4% *nornicotine*, 8.1% *anabasine*, 2.8% *nicotine*, 0.7% anatabine]; roots yielded 2.4817% alkaloids [52.9% *nicotine*, 32.3% *anabasine*, 13.4% *nornicotine*, 1.4% anatabine] (Saitoh et al. 1985; Webb 1948). In one test, only 0.0012% *nicotine* was found, from unspecified parts (Shaw et al. comp. 1959).

Other high-alkaloid species include N. benavidesii [1.46% in root], N. cordifolia [1.34% in root], N. exigua [1.2% in root], N. fragrans [1.49% in leaf; 1.33% in root], N. maritima [1.4% in root], N. nesophila [1.06% in leaf; 1.4% in root], N. nudicaulis [1.1% in root], N. raimondii [1.58% in root], N. spegazzinii [1.2% in root] and N. stocktonii [1.1% in leaf; 1.2% in root] (Saitoh et al. 1985).

Nicotiana tabacum is an erect, glandular-pubescent annual (or short-lived perennial) herb. Leaves alternate, sessile (the lower clasping the stem, semi-amplexicaul and decurrent), large (to 30cm long or more), oblong-lanceolate to ovate, apex acuminate, base cuneate, softly hairy and sticky, tender. Flowers solitary or several in axils and in terminal panicle- or raceme-like inflorescences; flowers bisexual, actinomorphic; calyx tubular to narrowly campanulate, connate margins often thin and translucent, calyx-teeth lanceolate, acute; corolla tubular or salver-shaped, rosy pink or reddish, limb 5-lobed, lobes usually folded in bud; stamens 5, only 4 or so reaching throat of corolla-tube; anthers bilocular, dorsifixed, not cohering, dehiscing longitudinally. Ovary bilocular; stigma capitate. Fruit a smooth-walled capsule c.1.5cm long, surrounded by persistent calyx, dehiscing from apex by 4 valves; seeds many, dark-brown, reniform to C-shaped, often angled, finely honeycombed or wrinkled on surface (Chopra et al. 1965; Haegi et al. 1982; pers. obs.).

Native to Central & South America [may be a cultivated hybrid of species originating in eastern valleys of the Bolivian Andes] (Furst 1976); widely cultivated.

Growing medium affects the taste of the resultant tobacco when smoked. The Greeks use sheep or goat dung to manure the soil, and the tobacco is very pungent [some add 'repulsive' to that description]; when they use cow dung, however, the flavour is milder and more pleasant. These tobaccos [fertilised with dung] are considered more suitable for snuffing, and smoking tobacco is often best fertilised with vegetable matter-derived compost. Plants fertilised with pig dung are said to produce tobacco that smells of 'anise' [see **Pimpinella**] (Von Bibra 1855).

Seeds are sown in early spring, once frosts have passed; seedlings planted out in late spring; harvested late summer. Lateral shoots are usually removed as they appear. Requires a well-drained, fertile nitrogen-rich soil, with regular deep watering and full sun; grows easily (French 1964; pers. obs.). This plant is nutrient-hungry, and will rapidly strip soil of its fertility. Global tobacco cultivation is having a detrimental effect on the land, and it is recommended that personal tobacco crops, if grown, be minimal in size, and regularly refurbished with organic compost. The seeds can also easily spread when capsules ripen, and the surrounding area should be monitored for escaped seedlings (pers. obs.).

When reaching maturity, the top of the plant is cut off to create more abundant leaf growth, and side-shoots are removed. Mature leaves are either harvested individually, or the whole plant may be cut at the base. The material is allowed to wilt and turn yellow, before being hung and dried [not too dry – this is a matter of expertise] for 8-10 weeks in a dark, well-ventilated room. For even colouring, leaves must be harvested at the same state of maturity. Midribs of leaves are resistant to drying, and need to be monitored for rot. The leaves are then assembled into parcels and stacked for careful fermentation [which develops the characteristic tobacco smell, taste and colour], with turning to avoid rotting. They are later spread and cooled, and sometimes a second fermentation is performed. The leaves may later be 'sauced', or soaked in a concentrated syrup of molasses and other plant extracts [to add extra aroma, taste, body, and sometimes subjective potency], before being dried, shredded and slightly moistened, or even left whole and twisted into sticks. Commercial tobaccos are often a blend of different tobaccos, with a unique individual method of curing and sauce recipe [including synthetic chemicals as well as plant extracts and other natural products]. It should be noted that the curing process causes considerable loss [15-25%] of *nicotine* (French 1964; Garner 1951; Lehane 1977; Von Bibra 1855). Proper curing of tobacco can be difficult when working with very small quantities.

Or, you can just dry the leaves and smoke them, with less loss of *nicotine*. This is much simpler, though it doesn't smoke the same as fully cured tobacco, burning quicker and having less taste and harshness (pers. obs.). Also, the powdered tobacco snuffs used in Amazonia are generally made with green, uncured tobacco.

NYMPHAEA and NUPHAR

(Nymphaeaceae)

Nymphaea alba *L.* **(N. candida** *C. Presl.***; N. minoriflora** *(Simonk.) Wissjul.***; Castalia alba** *(L.) W. Wood.***; C. speciosa** *Salisb.***)** – white water lily, shining water lily, flower of chastity

Nymphaea ampla *(Salisb.) DC.* **(Castalia ampla** *Salisb.***)** – white water lily, precious water lily, quetzalxochiatl

Nymphaea caerulea *Savigny* **(N. caerulea** *Andrews***; N. calliantha** *Conard.***; N. capensis** *Thunb.***; N. discolor** *Lehm.***; N. maculata** *Schum. et Thonn.***; N. mildbraedii** *Gilg.***; N. nelsonii** *Burtt-Davy***; N. nouchali** *Burm. f.* **var. caerulea** *(Sav.) Verdc.***; N. poecila** *Lehm.***; N. spectabilis** *Gilg.***; N. stellata** *Willd.***; N. vernayi** *Bremek. et Oberm.***)** – blue water lily, Cape blue water lily, Egyptian lotus, sacred lily of the Nile, nénuphar bleu de ciel, djaberi djongel

Nymphaea lotus *L.* **(N. liberiensis** *A. Chev.***)** – Egyptian lotus, white lotus, white water lily

Nymphaea lutea *L.* **(Nuphar lutea** *(L.) Sm.***; Nu. luteum** *(L.) Sm.***)** – yellow pondlily, brandybottle, great root, 'seat of the bullfrog'

Nymphaea pubescens *Willd.* **(N. lotus var. pubescens** *(Willd.) Hook. f. et Thomson***; N. nouchali** *Burm. f.***)** – night lotus

Nymphaea pumila *(Timm.) Hoffm.* **(N. lutea var. minima** *Willd.***; N. lutea var. pumila** *Timm.***; Nuphar lutea ssp. pumila** *(Timm.) E.O. Beal***; Nu. lutea var. pumila** *Timm.***; Nu. minima** *(Willd.) Sm.***; Nu. pailum** *Sm.***; Nu. pumila** *(Timm.) DC.***; Nu. subpumila** *Miki***; Nu. tenella** *Rchb.***)** – dwarf dock

Nuphar japonica *DC.* – Japanese yellow water lily

Nuphar variegata *Durand* **(N. variegatum** *Engl.***; N. lutea ssp. variegata** *(Durand) E.O Beal***; Nymphozanthus variegatus** *(Durand) Fernald***)** – North American yellow water lily

Nymphaea spp. and Nuphar spp. – water lilies

The Greeks claimed that N. alba grew from a nymph who died of jealousy, and they dedicated water lilies to the nymphs – later leading to the generic designation Nymphaea (Rätsch 1992; Viljoen & Notten 2002). The Greeks added N. alba to their wine [see *Methods of Ingestion*] for its tranquillising and parasympathetic activity. In Mediaeval times, monks and nuns would consume the plant as an anaphrodisiac to help them remain chaste. The roasted seeds have also been used as a coffee substitute [see **Coffea**]. The flower used to be plucked at night with blocked ears to protect against bewitchment by water spirits; once obtained, it was worn as a love amulet (Chiej 1984; Rätsch 1992). In Sierra Leone, the rhizome is used as an anticonvulsant (Lebbie & Guries 1995). In early experiments on eels, mice and dogs, the rhizome produced a spasmolytic activity, followed by narcosis (Emboden 1979b). In one human psychonaut, a tincture of the fresh flowers acted as a pleasant narcotic sedative (theobromus pers. comm.). It has been found to have similar psychotropic properties to N. caerulea [see below], though less potent (Jones 2002).

N. ampla is depicted in many Mayan murals and carvings, often in association with toad motifs [see **Bufo**] in a context suggestive of ritual use. It is also associated with themes of death, entailing visits to the underworld and subsequent rebirth (De Rios 1974, 1990; Emboden 1979a, 1979b). Westerners have been observed in highland Chiapas, Mexico, harvesting N. ampla bulbs and stems for use as a psychotrope. The plant is also used as a cardiac sedative in Afghanistan (Diaz 1979; Ott 1993). The flowers of N. ampla and N. caerulea have been noted as being 'narcotic'. Species found in the Antilles [identity not reported] have been used for their flowers as an effective opium substitute [see **Papaver**] (Emboden 1979b).

N. caerulea was a symbol of death and rebirth to the ancient Egyptians, and was held sacred to Osiris, who was said to have been reincarnated as a blue water lily after his murder by Seth. A text called "Transformation into the Water Lily" [or alternately lotus – see **Nelumbo**] from the Egyptian Book of the Dead makes reference to a blue water lily associated with Ra and Hathor, and the pure light of the sun. The incantation discusses the desire of Ani to "transform himself into the sacred blue water lily so that his body might have new birth and ascend daily into heaven." N. caerulea is widely depicted in ancient Egyptian art and relics, usually with ritual significance. It is often depicted with **Mandragora**, **Papaver** and toads [see **Bufo**], and was sometimes worn as an amulet. The flowers were also found with the mummified remains of Ramses II, and some other mummies. The flowers are thought to have been used as a ritual entheogen by ancient Egyptian priests (Emboden 1979a, 1979b; Faulkner 1972; Rätsch 1992). Recently N. caerulea has been identified as the 'Tree of Life' depicted in many myths and art-works of the ancient Middle East (McDonald 2002), and it has been proposed as the identifty of 'soma' [see **Amanita**] (McDonald 2004). In Guinea, a decoction of the flowers is taken for its narcotic effects and in Tanganyika, a root decoction is taken with **Ipomoea** aquatica leaf sap to treat 'mental derangement' (Burkill 1985-1997). In Zimbabwe, N. caerulea is taken orally to 'arouse spirits' (De Smet 1998). A root and stem infusion is emollient and diuretic, and the seed may be used to treat diabetes (Watt & Breyer-Brandwijk 1962).

A decoction or wine-infusion of 3-10 unopened N. caerulea flower

buds has narcotic, anaphrodisiac, mildly euphoric and antitussive effects; with wine infusions, some have described the effects as empathogenic. Adding too much flower material to wine results in a mucilaginous and foul-tasting beverage, although the effects may be stronger (pers. comms.). One source recommends using 7g of flowers per bottle of wine. They have also been soaked in cranberry juice [1g flowers per cup of juice] and the juice drunk, which in one bioassay was more 'incapacitating' than a similar wine extract. A smokeable extract of the flowers is similarly active, and has cumulative effects if taken over an extended period. Cumulative effects presumably develop with oral administration, also. The flowers themselves may also be smoked. One person described cumulative entheogenic effects from smoking flowers of a pink variety of N. caerulea [as N. nouchali], followed a day later by smoked N. alba flowers [see above]; this occurred after over a year of previous sporadic experimentation with different water lilies. The experience "lasted for four days and I found myself at times coexisting in two complete and separate worlds simultaneously", and by the third day included "extreme physical joy and mental and spiritual amazement". He noted that introspection and lack of social distractions may enhance the perceived effects. These preparations seem more effective when combined with alcohol. It seems that all of these observations may be applied to other Nymphaea spp., according to the current record of experimentation (friendly pers. comm.; Jones 2002).

N. lotus was held in high esteem by the Egyptians [similarly to N. caerulea – see above], and the flowers were given to honoured guests. The Greeks, after arriving in Egypt and observing this custom, applied the name 'lotos' ['precious'] to this plant. The 'lotophagi' or 'lotus eaters' referred to in Homer's Odyssey are thought to have been eating fruits of **Ziziphus** rather than a **Nymphaea** or **Nelumbo** (Burkill 1985-1997). Others doubt this, believing the effects of members of these latter genera adequately fit the description of the effects given by Homer (Jones 2001).

Gambian women sometimes chew N. lotus roots as a kola nut substitute [see **Cola**]. In Tanganyika, the root is decocted for its tranquillising properties, to treat 'mental derangement'. The roots are decocted in Nigeria as a respiratory stimulant, sedative for coughs, and fever remedy. The tea may also relieve insomnia. The leaf sap, or a decoction of the leaves, has been used as a sedative to treat hysteria and 'mad' people. The roots, leaves, and flowers have narcotic sedative effects, though the flower receptacle, seeds and cooked root are used as food (Burkill 1985-1997). The seed is regarded as a tonic food (Watt & Breyer-Brandwijk 1962). The flowers have similar effects to those of N. caerulea, though generally less potent (Jones 2002).

The Iroquois drink a root decoction of N. variegata to divine the cause of harmful magic. They also use the plant as a charm against witchcraft and demons, in varying ways, though for these purposes it is usually not ingested. A Nymphaea sp. known as 'Irupé' is respected by the Guarani, who say that its scent can enchant a person. They named this plant after a woman who drowned herself when learning of her husband's death, later transforming into a water lily (Rätsch 1992). In the Philippines, juice of N. pubescens is rubbed on the forehead and temples as a soporific; it has astringent and mild narcotic properties (Perry & Metzger 1980).

Aboriginal peoples of n. Australia use the processed rhizomes, seeds, flowers and stems of Nymphaea spp. as food, and drink the flower nectar [too much of which causes headache]. The flowering stems may be eaten raw, often after the outer skin is peeled away. Tubers are eaten after boiling or roasting on hot coals; 2-3 of them may cure diarrhoea. The seeds are ground to make flour for damper, which is cooked between the leaves. To indigenous people of Arnhem Land, Northern Territory, the water lily is the morning star, and its stalk is its path across the sky. The spirits of the dead follow this star after death to be led to their resting place (Isaacs 1987; Low 1991a; Smith et al. 1993).

These plants contain aporphine, sesquiterpene, and indolizine-type alkaloids which presumably synergise to produce the desired effects (pers. obs.). In some animal experiments, overdose of Nymphaea alkaloids [which may act in part as respiratory excitants] has caused death due to 'lung poisoning' (Burkill 1985-1997).

Nymphaea alba root bulb has yielded nympheine and nupharine [spasmolytic hypotensive]; root and seed also yielded tannonymphaein, nymphaetannic acid, citric acid, oxalic acid, malic acid, fat and resin. Flowers also contain the cardioactive glycoside nymphalin (Bulajewski & Modrakowski 1937; Bures & Hoffmann 1934; Chiej 1984; Schermerhorn et al. ed. 1957-1974). An extract causes excitation in animals, but larger doses lead to respiratory paralysis (Rätsch 1992).

N. ampla flowers have yielded aporphine, nupharine and nupharidine (Emboden 1979a; Rätsch 1992).

N. caerulea was claimed to have yielded nupharine, nupharidine and *nuciferine* (Emboden 1979a), though I could find no primary reference for this. Flowers have yielded delphinidin-anthocyanin derivatives, and 7 flavonoids which are rhamnoside derivatives of myricetin, quercetin and kaempferol (Fossen et al. 1999), which has MAOI effects (Sloley et al. 2000).

N. lotus has been shown to contain nupharine, nupharidine, nympheine and nelombine (Burkill 1985-1997).

N. lutea rhizomes have yielded nupharine, α-nupharidine [deoxynupharidine; tonic, hypertensive], β-nupharidine and nupharolutine [an isomer of nupharidine and castoramine]. Seed also contains nupharine; flower contains nymphalin and carotenoids. The plant has also yielded nuphacristine, and a great number of nupharidine-derivatives. A plant extract has anaphrodisiac effects (Achmatowicz & Mollowna 1940; Bulajewski & Modrakowski 1937; Cybulski & Wróbel 1989; Harborne & Baxter ed. 1993; Rätsch 1992; Schermerhorn et al. ed. 1957-1974; Wróbel et al. 1972). In one human psychonaut, a tincture of the fresh flowers had pleasant narcotic sedative effects (theobromus pers. comm.).

N. pumila rhizomes yielded 0.5% alkaloids, including (+)-nupharidine, (+)-7-epi-nupharidine, (-)-deoxynupharidine, (-)-7-epi-deoxynupharidine and traces of (+)-nupharopumiline [0.15% of total alkaloids], a new alkaloid (Peura & Lounasmaa 1977).

Nuphar japonica rhizomes have yielded anhydronupharamine (Forrest & Ray 1971); seco-dihydrocastoramine has also been found in the plant (Cybulski & Wróbel 1989).

N. variegata rhizomes have yielded 2.2% crude bases, containing the piperidine alkaloids nuphenine, 3-epinuphamine and 3-epinupharamine (Forrest & Ray 1971).

Nymphaea caerulea is a stout or weak aquatic herb with floating leaves; rhizome tuberous, thick, ovoid, 25-75mm long, 20-65mm thick, brownish. Leaves 8-30cm long, 6-28(-40)cm diam., oval, suborbicular or elliptic, coriaceous, base narrowly peltate, lobes obtuse or acute, divergent, nearly closed or overlapping, cleft nearly to centre where petiole is attached, margin entire or slightly undulate towards base, involute, incised-cordate, upper surface green, smooth, shiny, undersurface green, often speckled with crimson spots, particularly where bordering the margin, nervation raised or flat, primary lateral nerves 5-8(-10) on each side of midrib, 4-5 pairs of secondary nerves; petiole 30-50cm long or more, depending on water depth. Flowers sky-blue or pink to white, 6-20cm diam., broad, solitary, conical in bud; sepals 4, thick, not very different to petals, normally 4.3-8 x 1.1-2.5cm, lanceolate, or oblong-ovate to oblong-lanceolate, green externally, white to blue internally, sometimes marked with dark purple or reddish lines or dots, sometimes with reddish purple margins; petals 12-24, as long as sepals, lanceolate, oblong-lanceolate, obtuse or acute, some outer ones occasionally sepaloid, light blue above, whitening below (sometimes with colour variants of white, mauve or pink); stamens (30-)50-75(-100 or more?), bright golden yellow, externals broad, centrals short and narrow; anthers long-acuminate, in 2 parallel rows, terminating in connective, bluish, central stamens with broader anthers. Ovary almost hemispherical, of 14-21(-24) carpels; style short. Fruit depressed-globose, up to 4-6cm broad, 25-35mm high, truncated above; seeds numerous, very small, ellipsoid, ornate, with 17 longitudinal lines of very short hairs. Fl. spring to late summer. Dormant in winter.

In water; Egypt, widespread in tropical Africa and Transvaal (Berhaut 1979; Exell et al. ed. 1960-1993; Viljoen & Notten 2002).

This species should not be confused with N. caerulea *G. et Perr.*, which is also known as N. micrantha (Berhaut 1979).

It is worth noting that there is not universal agreement on the synonymy of Nymphaea lutea with Nuphar lutea, and Nymphaea pumila with Nuphar pumila (theobromus pers. comm.). Due also to variation in flower colour and growth forms, the taxonomy of water lilies is in a state of ever-changing confusion (Viljoen & Notten 2002).

Water lilies can be cultivated from division of the rhizomes in early spring, using pieces with budding leaf growth. Either plant in the bottom of a pond in a 15cm-deep mix of sand and compost, or grow in a pot sitting in the pond; top off with sand and pebbles. They require at least 30cm water depth, and full sun; they do not like quickly moving water or wind, and should not be planted near fountains. N. caerulea tolerates temperatures as low as -1(to -4)°C. Plants with developed leaves should be planted at a depth appropriate to petiole length, and later adapted to greater depths. Soil should be regularly enriched with organic fertiliser or compost, in non-natural settings; in natural stands, this is not needed due to natural accumulation of humus at the pond floor.

Seed may be difficult to collect before they disperse into the water, after the sudden bursting of the seed pods; a muslin bag may be tied over the ripening pods to ensure seed collection. Cultivate from seed spring to summer, in finely sieved loam soil low or deficient in organic matter; sow thinly, cover with a thin layer of soil, and submerge in water up to 2.5cm deep, in a sunny spot. Seeds should germinate within 3-4 weeks; prick out and repot in deeper water after the first several floating leaves appear (Viljoen & Notten 2002).

OCHROSIA

(Apocynaceae)

Ochrosia moorei *(F. Muell.) F. Muell. ex Benth.* **(Bleekeria moorei** *(F. Muell.) Koidz.***; Lactaria moorei** *F. Muell.***)**

Ochrosia nakaiana *Koidz* – yorodo

Ochrosia poweri *F.M. Bailey* **(O. newelliana** *F.M. Bailey***; Neisosperma poweri** *(F.M. Bailey) Fosberg et Sachet***)** – milkbush, red boat tree

The above plants yield an interesting array of indole alkaloids, though I am not aware of any ethnobotanical uses. In n.e. Australia, bark of O. elliptica ['Ochrosia plum'] has been used to treat malaria (Lassak & McCarthy 1990). O. borbonica is used medicinally in Reunion and Vietnam – its bark ['quinquina du paya'] treats fevers, and the leaves are used as a general tonic. In Java, a root decoction of O. oppositifolia treats stomach pain and seafood poisoning (Usher 1974).

O. elliptica bark and fruit from Cardwell, Queensland [Australia], harvested in August, tested strongly positive for alkaloids (Webb 1949).

O. moorei trunk bark has yielded 0.93% alkaloids, consisting of ellipticine, tetrahydroalstonine, reserpinine, reserpiline [elliptamine], rauvoxine, ochropposine, ochropposinine, ochrolifuanine and many other alkaloids; the plant has also yielded dihydrocorynantheol, 10,11-dimethoxy-*ajmalicine* and many other alkaloids from unspecified parts (Ahond et al. 1981; Buckingham et al. ed. 1994; CSIRO 1990).

O. nakaiana bark has yielded 0.38% alkaloids, consisting of *harman*, *vobasine*, reserpiline, *akuammidine*, venoterpine, serpentine chloride, and 10-MeO-corynantheol β-N-metho salt (Sakai et al. 1974); leaves have yielded 0.047% bornesitol (Nishibe et al. 1971a).

O. poweri bark has yielded isoreserpiline, ochropine and ochropamine; leaf has yielded *reserpine*, reserpiline, isoreserpiline, powerine, poweridine and poweramine (CSIRO 1990). Leaf, stem and bark from Queensland have all tested strongly-positive for alkaloids (Webb 1949).

Many of these alkaloids possess hypotensive and tranquillising properties, and some possess antitumour activity (CSIRO 1990). See also **Alstonia**, **Rauwolfia**, **Tabernaemontana** and **Vinca**.

Ochrosia poweri is a glabrous shrub or tree to 9m tall, with milky latex; terminal buds enclosed in a firm yellow gum. Leaves opposite or in whorls of 3, oblanceolate to obovate or elliptic, 6-14 x 2-5cm, apex mucronate or short-acuminate, gradually tapered to base, upper surface dark green and glossy, lower surface paler green; venation more prominent on upper surface, secondary veins 12-18 pairs, intramarginal vein present; petiole 2-10mm long. Flowers white, scented, in cymes, glands absent; corolla with a narrow, cylindrical tube c.7mm long, lobes c.5mm long, overlapping to the left in bud; stamens enclosed in tube, free from style head. Carpels free except for style; ovules few. Fruit a pair of bright red [in northern Australia; fruits on plants in n. NSW and s.e. Qld are bright yellow-orange] glossy drupes, sometimes only 1 developing, ellipsoid to ovoid, 2.5-4(-6 or more)cm x 12-16mm, apex pointed, endocarp thick, hard, nearly smooth; seed 1, flattened. Fl. autumn.

Subtropical rainforest, rare; north-central NSW, Queensland [Australia] (Harden ed. 1990-1993; comments in square parentheses are from observations of living plants communicated by Torsten 2001).

OCIMUM

(Labiatae/Lamiaceae)

Ocimum basilicum *L.* – basil, sweet basil, garden basil, tulsi, hsun ts'ao, lo le, babul, ajagandhika, albacar

Ocimum gratissimum *L.* **(O. frutescens** *L.***; O. guineense** *Schumach. et Thonn.***; O. viride** *Willd.***; Melissa cretica** *Lour.***; M. maxima** *Ard.***; Mentha perilloides** *Lam.***; Perilla avium** *Dunn***; P. frutescens** *(L.) Br.* **var. frutescens; P. ocymoides** *L.***; P. urticaefolia** *Salisb.***; Salvia infuscata** *Epling***)** – shrubby basil, vantulasi, ramtulasi

Ocimum micranthum *Willd.* **(O. campechianum** *Mill.***)** – pichanga, abaca, albahaca, iroro, fweroro

Ocimum sanctum *L.* – tulasi, sacred basil, sacred balm

Ocimum spp. are best known for O. basilicum, the common basil popularly used as a cooking herb, of which there are many varieties available commercially. O. basilicum and O. sanctum are native to India, and are esteemed there as sacred plants associated with Vishnu. Basil is said to have grown from one of Krishna's lovers. The Brahmans offer O. sanctum to Shiva and Vishnu, and Nepalese Vishnuites consider it to be an incarnation of Lakshmi, the Hindu goddess of love and luck. It is often planted around temples for its power to repel evil spirits and to heal, as well as being used magically to affect love and empathy. Wearing beaded segments of O. sanctum trunk around the neck apparently "induces religious tendency and longevity". It is so revered, that in some parts of India the plant is used in court to swear oaths on! Furthermore, basil [O. basilicum] was said to be found growing around Christ's tomb after the resurrection, and some Greek Orthodox churches use it to prepare their holy water [the name 'basil' comes from the Greek word for King]. Also in India, the seeds of O. basilicum are used as an aphrodisiac, in doses of 2-5.5g, and roots of O. sanctum are consumed as a nerve tonic. Many other Indian Ocimum spp., including O. gratissimum, are considered stimulants (Bremness 1988; Cunningham 1994; Kirtikar & Basu 1980; Nadkarni 1976; Rätsch 1992).

In Indo-China, the seeds of O. basilicum are taken as a sedative and antipyretic tea. Seeds of O. sanctum are used in similar ways in the Malay Peninsula, and in Indonesia, O. sanctum leaves are used in baths as a sedative, nervine and antipyretic (Perry & Metzger 1980). Indigenous people in Queensland, Australia, have been reported to drink an infusion of O. sanctum leaves as a tonic, for fevers and sickness (Webb 1948). In New Britain, Papua New Guinea, O. basilicum is used in rain magic (Paijmans ed. 1976). In Monterrey, Mexico, O. basilicum leaf and stem are infused as a sedative, calmative, stomachic and headache treatment (Nicholson & Arzeni 1993).

O. micranthum is used in Mexico as an analgesic and pediatric treatment. In Guatemala, it is decocted as an analgesic and anthelmintic, and in the s.w. Amazon Basin, it is used by the Sharanahua and Culina as an ayahuasca additive [see **Banisteriopsis**] (McKenna et al. 1995; Ott 1993; Pinkley 1969; Schultes 1972). In Peru, it is prepared with **Dictyoloma** peruvianum and given to decrease sexual desire in women. It is also used to make rattles ['schacapas'] which are shaken in the dark during ayahuasca ceremonies to heal, and to stimulate visions (Luna & Amaringo 1991).

O. basilicum is slightly stupefying, antibacterial, anthelmintic, stomachic, carminative, galactagogic and mosquito repellant. In India it is considered rejuvenating, antipyretic, diaphoretic, expectorant and blood-purifying; it is also sometimes used as a tonic and aphrodisiac, and stimulates the adrenal cortex (Bremness 1994; Chiej 1984; Kirtikar & Basu 1980; Polunin & Robbins 1992; Rätsch 1992). O. sanctum has shown analgesic, anti-inflammatory, antipyretic, antioxidant (Godhwani et al. 1987; Kelm et al. 2000), and anti-carcinogenic activity in animals (Aruna & Sivaramakrishnan 1992). An ethanol extract of the leaves was psychoactive in mice, and appeared to affect *dopamine* receptors (Sakina et al. 1990).

O. basilicum may yield c.0.25% essential oil from leaves, and c.1.5% from flowering tops, consisting of 23-86% *estragole*, 0.74-5.9% *eugenol*, *anethole*, *methyleugenol*, *safrole*, 0.37-1.43% *camphor*, and small amounts of *pinene*, camphene, myrcene, limonene, ocimene, linalool, terpineol, citronellol, geraniol, methyl cinnamate, p-MeO-cinnamaldehyde, p-MeO-benzaldehyde, bornyl acetate, thymol, dipentene, cymene, cineol, *borneol*, fenchol and sambulene; plant also contains vitamins A & C. The oil of the whole plant is predominantly *estragole*, and the oil from the flower spikes is predominantly linalool (Battaglia 1995; Bruneton 1995; Chiej 1984; Pogany et al. 1970; Polunin & Robbins 1992; Rastogi & Mehrotra ed. 1990-1993; Schermerhorn et al. ed. 1957-1974). Today, the chemistry of O. basilicum has become more complicated due to the development of a great variety of cultivars bearing different essential oil profiles.

O. gratissimum exists in methylcinnamate- and *eugenol*-dominant chemotypes; essential oil has also yielded *estragole*, carvacrol and thymol, though strains bearing *eugenol* do not seem to contain carvacrol or thymol, and vice versa (Bos et al. 1983; Fun & Svendsen 1991; Nadkarni 1976).

O. sanctum essential oil has yielded 71% *eugenol*, *eugenol* methyl ether, *estragole*, cineole, linalool, caryophyllene, carvacrol and methyl homoanisic acid (Perry & Metzger 1980; Webb 1948); aerial parts have also yielded cirsilineol, cirsimaritin, isothymonin, isothymusin, *apigenin*, luteolin, vicenin-2, vitexin, orientin, aesculin, aesculetin [see **Aesculus**], rosmarinic acid, *chlorogenic acid* and caffeic acid (Kelm et al. 2000; Skaltsa et al. 1999). Herbage harvested in April from Rockhampton [Queensland, Australia] tested positive for alkaloids (Webb 1949).

Ocimum basilicum is a strongly-scented erect branching herb, 60-90cm tall, glabrous or +- hispidly pubescent; stems and branches green or sometimes purplish. Leaves 2.5-5cm or more long, ovate, acute, entire or +- toothed, base cuneate, entire, petiole 1.3-2.5cm long. Flowers small, in 6-10-flowered whorls in dense racemes, the terminal raceme usually much longer than the lateral ones; pedicels with recurved tips; bracts small, caducous, stalked, shorter than calyx, ovate, acute; calyx 5mm, enlarged in fruit, very shortly pedicelled, ovoid or campanulate, 2-lipped, upper lip broad, flat, decurrent, erect in fruit, lower lip usually with 4 mucronate teeth, the 2 middle the largest; corolla 2-lipped, 8-13mm long, white, pink or purplish, glabrous or variously pubescent, tube short, not annulate within, upper lip subequally 4-fid, lower lip hardly longer than upper, declinate, entire, flat or nearly so; stamens 4, slightly exserted, upper filaments toothed at base; anther cells confluent. Ovary 4-partite; disc entire or 3-4-lobed; style lobes subulate or flattened. Nutlets 4, c.2mm long, ellipsoid, black and pitted.

Indigenous on lower hills of the Punjab; cultivated in India, Ceylon, Burma, and throughout much of the world (Kirtikar & Basu 1980).

Greenhouse-grown O. basilicum benefits from UV-B light supplementation [UV-B is virtually absent in greenhouse light], which increases phenylpropenoid levels [especially of *eugenol*] in the leaf, as well as levels of the terpenoids; in younger plants, only the phenylpropenes were increased (Johnson et al. 1999).

OLMEDIOPEREBEA

(Moraceae)

Olmedioperebea sclerophylla *Ducke* **(Maquira sclerophylla** *(Ducke) Berg***; Perebea xinguana** *Standl.***)** – rape dos Indios, Indian snuff

The bark, and sometimes fruits of this gigantic tree were once used in central Brazil by indigenous people of the Pariana area, to manufacture a snuff that presumably had psychoactive properties. Little else is known of it, but for a modern test, where a bark extract injected [i.p.] in rats produced "*amphetamine*-like" CNS-stimulation, followed by "motor incoordination, decreased exploratory activity, ataxia and muscle relaxation"; effects lasted c.30 minutes. No oral activity was observed (De Carvalho & Lapa 1990; Schultes 1967b).

O. sclerophylla bark contains cardenolides, steroids, phenols and terpenes, but no alkaloids were found (De Carvalho & Lapa 1990).

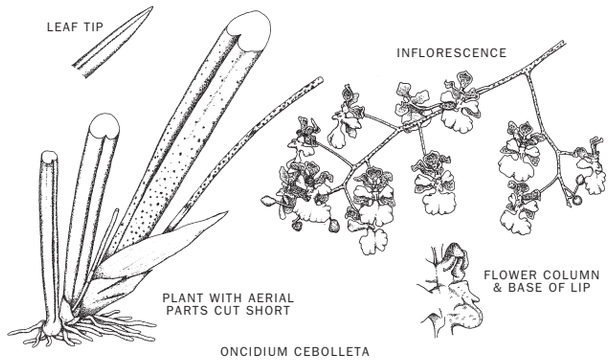
The related Maquira calophylla has caustic latex, and its bark contains furocoumarins (Schultes & Raffauf 1990).

Olmedioperebea sclerophylla is a tall tree 25-35m, monoecious or dioecious, lacticiferous, shedding leaves at end of rainy season; stems puberulent. Leaves coriaceous or chartaceous, elliptic-lanceolate, apex acuminate, base obtuse, 13-38 x 5-16cm, glabrescent above, scabridulous beneath, margin revolute, veins prominent, in 13-20 pairs; petioles 8-25mm long; stipules caducous. Staminate inflorescences up to 4 together, discoidal to subglobose, 3-12mm diam.; involucre with ovate, acute bract in 3-5 series; peduncles 1.5cm long, pilose; flowers free or basally connate; perianth c.2mm long, 4-lobed; stamens 3-6; anthers extrorse. Pistillate inflorescences solitary or with 1-2 staminate inflorescences, subsessile or pedunculate; peduncle 6-8mm long; involucre with reniform to ovate, acute or obtuse bracts in 3 series; flowers single and free or 2-4 basally connate; perianth 4-lobed; ovary inferior; stigmas 2, short, thick. Fruiting perianth usually globose, c.20mm high, 30-35mm long, puberulous.

In forests above flood level; lower Amazon of Brazil, north to Surinam (Off. Graphicas 1922; Schultes & Hofmann 1980).

ONCIDIUM

(Orchidaceae)



Oncidium cebolleta *(Jacq.) Sw.* **(O. brachyphyllum** *Lindl.***; O. cepula** *Hoffmanns.***; O. glaziovii** *Cogn.***; O. humboldtii** *Schltr.***; O. juncifolium** *(L.) Lindl.***; O. longifolium** *Lindl.***; O. sprucei** *Lindl.***; O. wittii** *Oppenheim***; Cohniella cebolleta** *(Jacq.) Christenson***; Cymbidium juncifolium** *(L.) Willd.***; Trichocentrum cebolleta** *(Jacq.) Chase et Williams***)** – cebolleta

This epiphytic orchid is considered to be a companion to [or substitute for] 'peyote' by the Tarahumara of n. Mexico, when **Lophophora williamsii** is not available. It is prepared by crushing the whole, fresh leaf in water, and this infusion is consumed. It may also be used as an external application to treat contusions and bone fractures; in this case, it is crushed with salt before application (Bye 1979b; Stermitz et al. 1983). It is not known whether the plant also has psychotropic effects as has been presumed, or if it simply serves as a medicinal substitute for peyote (pers. obs.). It has been claimed in recent horticultural literature that the seed pods "have potent psychotropic powers" (Banks & Perkins 2005), though the origin and accuracy of this information is unclear. The Huastec Maya of Mexico use O. carthagenense to treat headaches, and the Kofan of Colombia and Ecuador use O. pusillum as a topical antiseptic for cuts (Ott 1993; Schultes & Raffauf 1990).

O. cebolleta has yielded 0.006% 2,7-dihydroxy-3,4,6-trimethoxyphenanthrene, 0.0035% 2,7-dihydroxy-3,4,6-trimethoxy-9,10-dihydrophenanthrene, 0.014% 2,3-dihydroxy-4,7,8-trimethoxyphenanthrene, 0.0088% 2,7-dihydroxy-4,8-dimethoxyphenanthrene, 2,7-dihydroxy-3,4-dimethoxyphenanthrene (Stermitz et al. 1983), 1,5-dimethoxy-2,7-phenanthrenediol and nudol (Buckingham et al. ed. 1994). Some phenanthrenes produce sedation in rats, induce compulsive gnawing in mice, and pecking and emesis in pigeons (Castedo & Tojo 1990).

In an alkaloid screening, O. ansiferum, O. asparagoides, O. cheirophorum, O. globuliferum and O. warscewiczii were found to contain alkaloids; none were detected in O. cababrae, O. heteranthum, O. panduriforme, O. powellii, O. pulchellum or O. varicosum (Lüning 1967).

Oncidium cebolleta is a rhizomatous epiphyte, with pseudobulbs 1.5-2cm, conical to almost spherical, each with 1 leaf; sheaths enveloping pseudobulbs all leaf-bearing. Leaves terete, fleshy, 7-40cm, slightly grooved, erect, often tinged or spotted with purple, folded when young. Flowers numerous in a panicle to 1.2m, stalk spotted with purple; sepals 6-10mm, obovate, greenish-yellow with red-brown spots, not fleshy, usually spreading and clawed, lateral sepals free or variably united at base; petals similar to sepals, margins wavy, lip 3-lobed, with lateral lobes rather large, oblong or obovate, central lobe larger than sepals, shortly clawed, kidney-shaped, deeply notched at apex, yellow, callus consisting of a sharp projecting ridge surrounded by tubercles; column with a fleshy plate below the stigma, but without a foot, and with distinct oblong, sometimes 2-lobed, auricles on either side; rostellum short or beaked; pollinia 2, ovoid to spherical, stipe linear, longer than pollinia, viscidium small, making acute angle with stipe. Fl. spring.

Tropical America, from Mexico and West Indies to n. Argentina (Cullen ed. 1992; Dunsterville & Garay 1979). Slow growing; can be propagated by division, mounted on cork blocks or something similar. Enjoys lots of light, but not necessarily much full sun; prefers winter min. 16°C. Water regularly (Banks & Perkins 2005).

OPLOPANAX

(Araliaceae)

Oplopanax horridus *(J.E. Smith) Miq.* **(Echinopanax horridum** *(Sm.) Decne. et Planch.***; Fatsia horrida** *(Sm.) Benth. et Hook. f.***; Panax horridum** *Sm.***)** – devil's club, Alaskan ginseng

Oplopanax japonicum *(Nakai) Nakai* - haribuki, jigoku bara

The juice from the roots or bark of this plant was once used as the sole intoxicant of Tlingit shamans, who consumed it to receive dream visions and "magical powers of great strength". It was also said to increase the ability of the shaman to hypnotise and control others. To the Tlingit, it is said to be the "most important medicinal and magical plant of all", and they also use it as an emetic, purgative and poultice. The Eyak have also used the plant 'ceremonially', and elsewhere in Alaska it has been applied externally as a "prophylactic against witchcraft". The inner bark and root have been used to treat skin infections, burns, rheumatism, diabetes, tuberculosis, colds, sore throats, headaches, constipation and lung haemorrhages (Kobaisy et al. 1997; Lipp 1995; Smith 1983). One psychonaut who investigated the psychoactive effects of the plant reported that it gave him "a noticeable sedative buzz" (Hoodoo pers. comm. 2001). Young shoots and peeled roots are apparently eaten as a survival food in the Pacific Northwest. In rural Japan, leaves and stems of O. japonicum are boiled to make a mildly stimulant tea, which also treats colds (Brussell 2004).

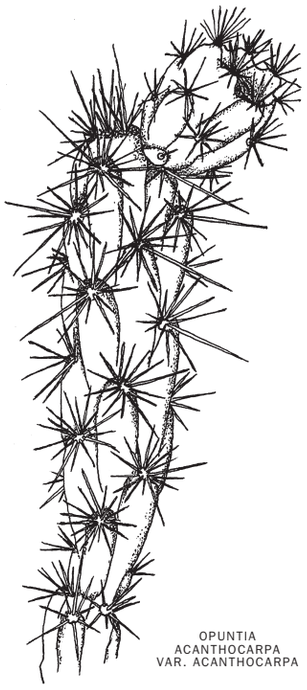
O. horridus inner stem bark has yielded 1.3% falcarindiol, 1.12% oplopandiol, 0.65% oplopandiol acetate, 1.6% 9,17-octadecadiene-12,14-diyne-1,11,16-triol,1-acetate and falcarinol (Kobaisy et al. 1997); root bark has yielded the sesquiterpenes trans-nerolidol [major component; nerolidol is sedative and spasmolytic in mice], α-cubebene, oplopanone [antipyretic, antitussive] and spathulenol, as well as stearic acid, stigmasterol [antirheumatic], β-sitosterol [anticholesteremic], lignan 1,3-benzodioxole, and 5,5'-tetrahydro-1H,3H-furo[3,4-c]furan-1,4-diyl)bis [original reference made it unclear whether these last two compounds were actually meant to go together as the name of a single compound; an opening bracket was also not included in the name]. Extracts of the inner bark may have antipyretic, antitussive, antibacterial and hypoglycaemic activity; extracts from unspecified parts showed antifungal and antimicrobial activity (Bloxton et al. 2002); the root extract also shows hypoglycaemic activity. Severe hypoglycaemia can lead to convulsions and a state of unconsciousness "in which meaningful dreams may be experienced", though it is uncertain as to whether this is the pharmacological cause of the intoxication (Lipp 1995; Smith 1983).

Oplopanax horridus is a spiny shrub 1-3m tall, densely spiny on stem, petioles and leaf veins. Leaves long-petioled, nearly rotund in general outline, 5-7-lobed, up to 35cm long and wide, cordate at base, lobes acuminate or cuspidate, serrate. Inflorescence numerous crowded, head-like umbels in ample terminal racemes; calyx small, its limb truncate to denticulate; petals 5, valvate or scarcely imbricate, usually distinct, deciduous at maturity; stamens 5, inserted on disc within calyx; anthers short, longitudinally dehiscent. Ovary inferior, 2-celled, with 1 anatropous pendulous ovule in each cell; styles 2, separate to the base. Fruit a berry or leathery drupe. Fl. Jun.

In wet woods and ravines, forming almost impenetrable thickets; Isle Royal, Michigan, Alaska to Montana and Oregon (Gleason 1952; Smith 1983).

OPUNTIA

(Cactaceae)



OPUNTIA
ACANTHOCARPA
VAR. ACANTHOCARPA

Opuntia acanthocarpa *Engelmann et Bigelow* **(O. thornberi** *Thornber et Bonker***; Cylindropuntia acanthocarpa** *(Engel. et Big.) F. Knuth***)** – buckthorn cholla, major cholla

Opuntia basilaris *Engel. et Big.* **(O. basilaria** *Engel. et Big.* [incorrect spelling]**; O. intricata** *Griffiths***; O. whitneyana** *Baxter***)** – beavertail cactus, wo-gay-be, nah-vombi, devil's rope

Opuntia brasiliensis *(Willdenow) Haworth* **(O. argentina** *Grisebach***; O. bahiensis** *Britton et Rose***; O. neoargentina** *(Backeberg) Rowley***; O. schulzii** *Castellanos et Lelong***; Brasiliopuntia bahiensis** *(Br. et R.) Berger***; B. brasiliensis** *(Willd.) Berg.***; B. neoargentina** *Backeb.***; B. schulzii** *(Castell. et Lel.) Backeb.***; B. subacarpa** *Rizzini et Mattos***)** – Brazilian cactus, cha'i [?], tchai [?]

Opuntia echinocarpa *Engel. et Big.* **(O. deserta** *Griff.***; Cylindropuntia echinocarpa** *(Engel. et Big.) F. Knuth***)** – silver cholla, golden cholla

Opuntia ficus-indica *(L.) Miller* **(O. cordobensis** *Spegazzini***; O. ficus-barbarica** *Berger***; O. tuna-blanca** *Speg.***; O. vulgaris** *Mill.***; Platyopuntia cordobensis** *(Speg.) Ritter***)** – Indian fig, Barbary fig, common prickly pear, mission cactus, chumbera, penca, barshoom, raquette, tunas

Opuntia imbricata *(Haworth) DC.* **(O. decipiens** *DC.***; O. magna** *Griff.***; O. spinotecta** *Griff.***; O. vexans** *Griff.***; Cylindropuntia imbricata** *(Haw.) F. Knuth***)** – cane cholla, tree cholla, coyonostli

Opuntia leptocaulis *DC.* **(O. ramulifera** *Salm-Dyck***; Cylindropuntia brittonii** *(J.G. Ortega) Backeb.***; C. leptocaulis** *(DC.) F. Knuth***)** – Christmas cholla, desert Christmas cactus, jumping cactus, coyote cactus, pencil cholla, turkey pear, tasajillo

Opuntia spinosior *(Engel.) Toumey ex Bailey* **(O. whipplei var. spinosior** *Engelm.***; Cylindropuntia spinosior** *(Engelm.) F. Knuth***;** sometimes traded commercially as **O. arborescens var. spinosior)** – cane cholla

A vessel retrieved from an archaeological site in northern Peru [c.500AD] depicts male and female jaguars [a well-known shamanic animal in Central and South America] with dilated pupils, in association with what appears to be enema paraphernalia adorned with Opuntia sp. pads (Trout & Friends 1999); the implications are interesting to say the least!

The Sharanahua of the Peruvian Amazon cultivate an unidentified Opuntia sp., called 'cha'i' or 'tchai' [see also **Lygodium**], which they obtained from the nearby Amahuaca. It has been added to ayahuasca [see **Banisteriopsis**]; the resultant combination was reported to be "very strong and is never used medicinally" (Rivier & Lindgren 1972; Schultes 1972). Sometimes it was consumed before drinking ayahuasca, in order to "increase the hallucinations" (Harner in Stuart 2002b). It is rarely used today with ayahuasca, as it was considered to be "too intense", but the raw juice of the cactus is still used alone, purportedly as an entheogen, by some amongst the Amahuaca and Shipibo. Although it has not yet been properly identified, it is similar in appearance to O. brasiliensis (Stuart 2002a, 2002b; Trout & Friends 1999), and is reported to bloom in the wild between mid-May and mid-July with blue and white flowers. Three varieties of tchai are recognised – large, medium, and small – although it is still not known whether these represent different species. The large variety is considered the most potent medicinally; one Shipibo man claimed that it "was only used by brujos for sorcery, although with special precautions it might also be used by a curandero for healing". The smaller varieties are considered either less useful medicinally, or useless; others regard all Opuntia spp. with pads as having similar medicinal properties [eg. externally for wounds, internally for rheumatism, stomach ache, diarrhoea, body aches] (Stuart 2002a).

A closer investigation of the presumed psychoactivity of this plant resulted in R. Stuart keeping a diet prescribed by a Shipibo shaman and consuming tchai prepared by the shaman over four nights, in an attempt to meet the 'mother spirit' of the plant. The initial dose was 2 branch pads, going up by 2 pads each night to culminate in a final dose of 8 pads. Each dose was prepared by mashing the pads to a pulp with a smooth stone, mixing the pulp with water and a "large pinch of tobacco" [see **Nicotiana**], blowing tobacco smoke and singing over the brew, and drinking it cold. Although some doses resulted in vomiting or strange bodily sensations, perhaps attributable to the tobacco present, no definite psychoactivity was perceived. A later bioassay, which involved consuming the green pulp of 18 pads [c.77g] with ¾ tsp **Peganum** harmala seeds after having fasted for 24hrs, also resulted in no psychoactivity (Stuart 2002a, 2002b).

The fruits of O. leptocaulis are "known among the Spanish-Americans as tasajulla and garrambulo", and are added to 'tulbai', a chicha-like corn-based beverage [see *Methods of Ingestion*]. The berries are said to be narcotic on their own, with a single fruit claimed to "make one 'drunk and dizzy'", though cactophiles who have eaten the fruits based on this report did not experience any psychoactive effects (Smith 2000). It has been suggested that an alcohol tincture might be more effective (theobromus pers. comm.).

The Zuni of N. America grind O. imbricata under their armpits during warrior initiation (Benson 1982). The Hopi drink a decoction of O. whipplei roots with globe mallow to treat diarrhoea. The Navajo, and some Californian tribes, apply the peeled stems of Opuntia spp. to skin disorders (Winter 1998). A number of Opuntia spp. have been applied to treat cancerous tumours in the Americas, including O. ficus-indica, O. moniliformis and O. pseudo-tuna (Hartwell 1968). In Spain, O. ficus-indica stem ['palas'] is heated and applied externally for pain and respiratory problems; the flower is infused to treat diarrhoea (Martinez-Lirola et al. 1996). In S. Africa, this species is used as a host to rear the 'cochineal beetle' [Dactylopius coccus]; this is also a practice in Peru and the Canary Islands (Brutsch & Zimmermann 1993). Several tribes in the Golden Triangle of n. Thailand cultivate O. dillenii in their villages to ward off evil spirits (Anderson 1993).

From Australia, there has been an unsubstantiated report of indigenous people near Tennant Creek [NSW] consuming flesh or juice of an Opuntia sp. in large quantity to reach a state of stuporous intoxication for several hours, sometimes with 'violent' side effects. Those intoxicated were also observed to be easily startled and suffer apparent fear of the dark. More precise details are lacking (Torsten pers. comm.).

Many Opuntia spp. have been shown to contain varying quantities of *mescaline*. Although most quantified so far have been minor, the verified shamanic use of an unidentified Opuntia sp. [see above] would suggest that some species and strains might prove to be potent.

O. acanthocarpa contained c.0.01% *mescaline*, 0.1% *DMPEA* and <0.01% 3,5-dimethoxy-4-OH-*phenethylamine*.

O. basilaris contained c.0.01% *mescaline* and <0.01% 3,5-dimethoxy-4-OH-*phenethylamine* (Ma et al. 1986).

O. cylindrica [Austrocylindropuntia cylindrica] has yielded no alkaloids yet (Agurell 1969a); another study claimed to have found 0.9% *mescaline* (Turner & Heyman 1960), though the specimen tested was actually **Trichocereus** pachanoi, which strangely was once confused with O. cylindrica (Agurell 1969a), a very different plant!

O. echinocarpa contained c.0.01% *mescaline*, 0.01% *DMPEA* and 0.01% 3,5-dimethoxy-4-OH-*phenethylamine* (Ma et al. 1986).

O. ficus-indica has yielded *mescaline*, *tyramine*, N-methyl-*tyramine* (El-Moghazy et al. 1982) and *phenethylamine* (Lundstrom 1989), as well as mucilage containing glucose, galactose, arabinose, rhamnose, xylose, glucuronic acid and galacturonic acid; flower petals yielded the flavonoids kaempferol, luteolin, penduletin, quercetin, quercitrin and rutin; fruit yielded 0.09% ascorbic acid [vitamin C], as well as other acids (El-Moghazy et al. 1982), including piscidic acid, and indicaxanthin. Stem and fruit of O. ficus-indica var. saboten were found to inhibit MAO, more potently on MAO-B; 1-monomethyl citrate, 1,3-dimethyl citrate, trimethyl citrate and 1-methyl maleate were isolated and shown to share this activity (Han et al. 2001).

O. imbricata has yielded *mescaline*, *tyramine*, 3-MeO-*tyramine*, *DMPEA*, and an unidentified alkaloid (Meyer et al. 1980).

O. polyacantha was shown to yield 0.007% opuntiol [2-OH-methyl-4-MeO-α-pyrone] when under investigation for alkaloids; however, no alkaloids were actually reported (Telang 1973).

O. spinosior has yielded 0.00004% *mescaline*, 0.0018% *tyramine*,

0.0011% 3-MeO-*tyramine*, and traces of *DMPEA* (Kruger et al. 1977; Pardanani et al. 1978).

In a screening of Argentinian Opuntia spp., all samples tested contained alkaloids (Falco & Hilbug 1949). The genus has also been shown to contain betacyanins, betaxanthins, flavonoids [including quercetin 3-methyl ether] and their aglycones, oleanane triterpenoids; and less interesting phenethylamines are found in some other species (Trout ed. 1999).

Opuntia acanthocarpa forms an arborescent shrub 1-3(-4)m tall; trunk short, to 10-15cm diam. Larger terminal branches 12-50 x 2-3(-4)cm; tubercles conspicuous, sharply raised and laterally compressed, (12-)20-25(-50)mm long, +-4.5mm wide and high; leaves slender, tapering, roughly as thick as wide, +-12mm long, +-1.5mm diam.; areoles circular, 5-6mm diam., 2-4cm apart; spines tan to reddish-tan, to straw-coloured or whitish, turning brown, later black, 6-25 per areole, spreading, straight, longer ones 1.2-2.5(-4)cm long, 0.8-1.2mm thick at base, subulate, narrowly linear in cross-section; spines with conspicuous sheaths, straw-coloured, rarely silvery, persisting for c.1 year; glochids minute. Flowers 4-5.5cm diam., 4-6cm long; sepaloids greenish-yellow to greenish-red, broadly spatulate, to 20mm long, to 20mm wide in upper parts, rounded; petaloids of variable colour (usually red, purplish or yellow), narrowly obovate, 25-40mm long, up to 15mm wide, rounded, mucronulate, with a few shallow sinuses; filaments 9-12mm long; anthers to 3mm long; style 15-20 x 2-3mm; stigmas 5, broad, 3-4.5mm long; ovary spiny in anthesis. Fruit deciduous in late summer or autumn, turning tan or brown and dry, tuberculate, with numerous spreading spines except at base, obovoid-turbinate, 2.5-4 x 1.5-2cm, with deep, cup-like umbilicus; seeds pale tan or whitish, flattened, irregularly angular, 5-8 x 3-5 x 2-3mm.

The varieties of this species can be divided as follows:-

O. acanthocarpa var. acanthocarpa – 1.2-1.8m tall; few joints, forming acute angles, joints 20-50cm long, +-3cm diam.; tubercles 30-38mm long, broad; 15-20 spines per areole, +-2.5cm long; in gravelly or sandy soils at desert edge, also in woodland and brush; Mojave desert, Utah, Arizona, +-1200m.

O. acanthocarpa var. coloradensis – 1.2-1.8(-4)m tall; joints as above, but 15-30 x 2-2.5cm; tubercles 20-23mm long, narrow; 10-12 spines per areole, 2.5-4cm long; sandy or gravelly soils; Mojave desert, Sonoran desert, California, Colorado, Utah, Arizona, 600-1300m.

O. acanthocarpa var. ganderi – 0.9-1.2m tall; joints as for var. acanthocarpa, but 3-4cm diam.; tubercles 12-16mm long, narrow; spines dense, obscuring stem, 15-25 per areole, 1.2-3cm long; in sand and gravel on flats and hillsides, Colorado desert, and edge of California chaparral, 300-900m.

O. acanthocarpa var. major – sprawling, diffuse, 0.9-1.5m tall; joints numerous, with many obtuse angles, 12-25 x 2-2.5cm; tubercles 20-25mm long, narrow; 10-15 spines per areole, +-2.5cm long; sandy soils, mainly in Arizona desert, Arizona, California, Sonora [Mexico], 300-900m.

O. acanthocarpa var. thornberi – diffuse, 0.9-1.5m tall; joints forming acute and obtuse angles, 25-50 x +-2cm; tubercles 30-50mm long, narrow; spines sparse, not obscuring stem, 6-11 per areole, 1.2-2.5cm long; sometimes no or few spines on fruit; rocky or gravelly soils, on hillsides and ridges, upper edges of Arizona and Mojave deserts (Benson 1982).

Opuntia spp. forming flat pad-like branches are referred to colloquially as 'prickly pears'; those forming +- cylindrical branches are known as 'chollas'.

OSTEOPHLOEUM

(Myristicaceae)

Osteophloeum platyspermum *(Spruce ex DC.) Warburg* **(O. platyphyllum** *Holmstedt et al. nomen nudum***; O. sulcatum** *Little***; Myristica platysperma** *Spruce ex DC.***; Palala platysperma** *(Spruce ex DC.) Kuntze***)** – cumala blanca, cumala, machin cara yura ['capuchin monkey bark tree'], ilauta caspi, huapa, anya huapa, huachig caspi, tungebanpe, ta-le-mee-na, archireeupa, lacre de mata, uccuuburana, uccuuba branca

The Quicha of Amazonian Ecuador once used the sap of this tree as an orally-administered hallucinogen to communicate with the spirit world. Mature trees, yielding large quantities of sap, were scored across the bark of the trunk, and the red sap collected in a leaf-vessel. This was cooked, sometimes with pieces of bark as well, and drunk when cooled. It was sometimes mixed with a **Brugmansia** sp. known as 'guandu', and 'tsicta' [**Tabernaemontana** sananho], and was said to be fatal in excessive quantities. The Quicha also would put a few drops of the sap into the noses of their dogs to improve their senses (Bennet & Alarcon 1994).

The Maku drink the sap to cure coughs and colds. The Kuripako burn the leaves in their homes to cleanse the dwelling after a serious illness. The Makuna and the Ingano use the inner bark as a poultice for wounds, and Colombian Amazonians use the sap to aid in wound healing (Schultes 1978; Schultes & Raffauf 1990). Labourers in the Reserva Ducke, near Manaus, inhale the smoke from the burning leaves to relieve asthma (Fo et al. 1984). It should be noted that the vernacular names 'cumala' and 'cumala blanca' are also applied to some **Iryanthera** spp. (Schultes & Holmstedt 1971), **Theobroma** spp. and **Virola** spp.

While one sample yielded 0.62% alkaloids from the dry bark, consisting of *DMT*, *5-methoxy-DMT* and *bufotenine*, others contained no tryptamines at all. Leaves have yielded abrine methyl-ester [N-methyl-*tryptophan* methyl ester] (Holmstedt et al. 1980; McKenna et al. 1984b), δ-cadinene, (-)-kaur-16-en-19-oic acid, eperu-7,3-dien-15-ol-18-al, eperu-13-en-8β,15-diol and eperu-8(20),13-dien-3α,15-diol. Branches and leaves together have yielded (-)-kaur-16-en-19-oic acid, stearic acid, sitosterol, stigmasterol, (+-)-maackiain and (+-)-3-demethylhomopterocarpin. Fruits have yielded eperu-8(20),13-dien-3α,15-diol, sitosterol, glyceryl laurodimyristate, glyceryl 1,3-lauromyristate and neolignans [guaiacin, otobaphenol, hydroxyotobain, hydroxyoxyotobain and dihydroguaiaretic acid] (Fo et al. 1984). Pharmacology of this plant is poorly known.

Osteophloeum platyspermum is a dioecious tree to 40m; branches and branchlets terete, minutely and densely puberulent with sessile, stellate, 4-6-branched hairs, later glabrous. Leaves alternate, simple, entire, (8-)10-15(-20)cm long, 3.7-5(-6.5)cm wide, oblong-obovate, coriaceous, velvety and translucent (not hyaline) when young, later glabrous, often shiny above, minutely punctate and often ceriferous beneath, often slightly emarginate, margins narrowly revolute, apex rotundate or rounded, base acute-cuneate or gradually attenuate, pinnately nerved, lateral nerves (6-)7-9(-12) on both sides, semi-spreading, tertiary nerves scarcely distinct; petiole (1.5-)1.9-2.5(-3)cm long. Inflorescences 1-3 in leaf axils or on defoliate branchlets, subumbellate, simple or with 1-4 short, lateral branches; male inflorescence densely pubescent externally, 1-6cm long; peduncle 2.5-3.8cm long, paired, axillary and above axils; pedicels bracteolate at apex, (in male) branched at apex, bearing 5-6 flowers, to 5mm long; bracts small; bracteoles tiny, semiorbicular, later short-rotundate, sessile, surrounding base of flower, c.2mm wide, 1mm long; flowers solitary or in irregular fascicles of 2-8, apetalous; perianth c.4mm long, ovoid-obtuse, carnose, glabrous inside, 3-lobed nearly to base, lobes valvate; androecium 2.5-3mm long, filaments connate into a carnose column 1mm long or less; stamens (2-)3-10; anthers (6-7?)12(-14), linear, crowded, fused at apex, 2-celled, dehiscing longitudinally. Ovary superior, sessile, conic, densely and minutely lepidote-tomentellous, 1-celled; ovule 1, +-basal; stigma sessile, oblique. Fruiting inflorescences glabrous throughout when mature; fruits few, fleshy, depressed-globose, transversely ellipsoid, 15-25mm long, 20-25mm broad, conspicuously bicarinate, valved, furrowed, pericarp 0.5-1.5mm thick, woody, covered by an aril, aril obscurely laciniate; pedicel twice as long as fruit; seed c.½ as long as broad, uniform in colour.

Peru [Loreto, mouth of Rio Santiago; Iquitos; Amazon river], Amazonian Colombia, n. Amazonian Brazil [Panure, Rio Uaupes, Rio Negro] (De Candolle 1856; Smith 1938).

OXYTROPIS

(Leguminosae/Fabaceae)

Oxytropis lambertii *Pursh* – crazyweed, loco, locoweed, Lambert's locoweed, purple locoweed, stemless locoweed

Oxytropis puberula *Boriss.* **(O. glabra var. roschanica** *B. Fedtsch.***)** – rakhdzham

Oxytropis sericea *Nutt. ex Torr. et. Gray* **(O. albiflora** *(A. Nelson) A. Nelson***; O. condensata** *(A. Nelson) A. Nelson***; O. pinetorum** *(A. Heller) K. Schum.***; O. saximontana** *(A. Nelson) A. Nelson***; O. vegana** *(Cockerell) Wooton et Standl.***)** – locoweed, white locoweed, white point locoweed, silky crazyweed, silvery oxytrope

Oxytropis spp. ['milkvetches'] are widespread herbs often used as fodder plants for stock animals. However, some species are known to be toxic, causing intoxications in animals (Allen & Allen 1981; Culvenor 1970; Keeler 1975; Komarov et al. ed. 1986). O. lambertii and O. sericea are known as 'locoweeds' in North America [see also Astragalus in *Endnotes*], causing sometimes fatal intoxication in horses and other stock animals. However, some feeding tests on animals using O. lambertii and some Astragalus spp. did not reveal any adverse effects (Anon. 1888b; Kingsbury 1964; Molyneux & James 1982; Pammel 1911). Prairie 'Indians' from South Dakota may have ingested some locoweeds to induce visions (Rätsch 1992).

O. glabra has yielded the alkaloids anagyrine, sparteine [see **Cytisus**, **Laburnum**, **Lupinus**], thermopsine and adenine, as well as terpenoid saponins and flavonoids (International... 1994).

O. montana and O. uralensis contain canavanine [see **Canavalia**] (Bell et al. 1978).

O. pseudoglandulosa contains alkaloids in the whole plant – N-benzoyl-2-OH-*phenethylamine*, 2-benzoyloxy-*phenethylamine* and (E)-N-2-phenylethylcinnamide; as well as the flavonoids chrysin [see **Passiflora**] and isoliquiritigenin [MAOIs (Hatano et al. 1991; Sloley et al. 2000)], and the waxy hydrocarbon-derivatives hentriacontane, heptacosane, non-

acosane, pentacosane and tricosane (International… 1994).

O. puberula aerial parts have yielded *harmine*, (-)-N-nicotinoyl-2-OH-*phenethylamine* and β-sitosterol glucopyranoside (Akhmedzhanova et al. 1995); the plant has been noted to be toxic to animals (Komarov et al. ed. 1986).

O. sericea has yielded the toxic alkaloids swainsonine and swainsonine N-oxide [see **Swainsonia**] (Molyneux & James 1982).

Oxytropis puberula is a perennial herb; stems few, 4-70cm long, nearly erect, branching in upper part, +- puberulent. Leaves 7-10cm long, pinnate; leaflets 5-7-paired, oblong-oval or oval-lanceolate, 10-20(-40)mm long x 2-5(-10)mm wide, covered on both sides with fine appressed hairs, sparser above; stipules ovate, 7-12mm long, not adnate to petioles, connate at base, spreading-hairy. Inflorescences oblong racemes, 5-10cm long; pea-flowers subsessile, peduncles as long as leaves or longer; bracts narrowly linear, c.2mm long, acute, long-hairy; pedicels very short; calyx campanulate, c.3mm long, densely short-puberulent, teeth lanceolate, ½ as long as tube; corolla violet, standard 6-8mm long, limb orbicular and slightly emarginate at apex, wings shorter than standard, keel slightly shorter than wings, beak c.1mm long. Fruit oblong-oval or oblong pods, (7-)8-15mm long, 4-6mm wide, compactly membranous, inflated, dehiscing at ventral suture, beak and stipes c.1mm long, pendulous with short black and white spreading hairs. Fl. Jul.-Aug.

In valleys, pastures, on riverbanks, near lakes, roadsides; endemic in central Asia (Komarov et al. ed. 1986).

PACHYCEREUS

(Cactaceae)

Pachycereus pecten-aboriginum *(Eng.) Britton et Rose* **(Cereus pecten-aboriginum** *Engelmann***)** – cardón, cardón hecho, hecho, cawé, chawé, wichowaka, bitaya mawali, pitahayo, organo

Pachycereus pringlei *(S. Watson) Br. et R.* **(Cereus pringlei** *S. Watson***)** – cardón, cardón pelón, sahueso, senita, xáasx, elephant cactus, Mexican giant cactus

The Tarahumara of Mexico prepared a ceremonial beverage called 'cawé' or 'chawé', from P. pecten-aboriginum. The brew is said to produce 'dizziness and visions'. The young branches are crushed in a hollow rock, and the juice added to water [roughly 1:3]. The resulting preparation is consumed under ritual circumstances. Sometimes the sap is added to corn beverages [eg. 'chicha' – see *Methods of Ingestion*]; sometimes it is cooked and fermented by itself, in which form it is said to act as a strong purgative. The seeds are also known to be ground into a flour for food, and its spiny fruit is used as a hairbrush. The cactus has also been used medicinally, to treat cancer [success rate not reported!], gastric ulcers (Bruhn 1973; Bruhn & Lindgren 1976; Bye 1979b; Hartwell 1968; Usher 1974) and "general aches and pains" (Salmón 1995).

Flesh from the related P. pringlei has been claimed to have 'inebriating' properties (Smith 2000). Amongst a group of people who all consumed similar doses of material from the same sample, some experienced psychedelic inebriations, whilst others experienced only strong nausea and vomiting (Shulgin pers. comm. 2002). Stems of P. pringlei have also been given as a decoction [orally or rectally] to treat cancer of the uterus, in Mexico (Hartwell 1968). The Seri of Sonora use a heated, de-spined slice of the stem wrapped in cloth, to apply to aches and rheumatic pains (Felger & Moser 1974).

The fermented beverage prepared from P. pecten-aboriginum might be aided by the presence of a Drosophila-yeast relationship, as seen with **Carnegiea**. P. pecten-aboriginum is known to be host for the fruit fly Drosophila nigrospiracula, as well as what was thought to be D. spencceri (Kirscher & Heed 1970). Pichia heedii, the yeast also associated with **Carnegiea**, is known to be associated with some 'pachycereoid' cacti (Holzschu & Phaff 1982).

P. pecten-aboriginum has yielded 0.01-0.05% alkaloids [w/w], of which up to 10% was isohomovanillylamine [3-OH-4-MeO-*phenethylamine*], as well as homovanillylamine [3-MeO-*tyramine*; 3-MeO-4-OH-*phenethylamine*], *DMPEA*, and the tetrahydroisoquinolines arizonine [8-OH-7-MeO-1-methyl-THIQ], carnegine [6,7-dimethoxy-1,2-dimethyl-THIQ; pectenine; see **Carnegiea**], salsolidine [main alkaloid; N-norcarnegine; 6,7-dimethoxy-1-methyl-THIQ][produced tremors in mice; MAOI], salsoline [6-OH-7-MeO-1-methyl-THIQ; MAOI], isosalsoline [MAOI; salsoline and isosalsoline caused tremors, convulsions and decreased motor activity in mice] and heliamine [6,7-dimethoxy-THIQ]; quinic acid was also found (Agurell et al. 1971; Bembenek et al. 1990; Bruhn & Lindgren 1976; Lundstrom 1989; Shulgin & Shulgin 1997; Strömbom & Bruhn 1978; Unger et al. 1980).

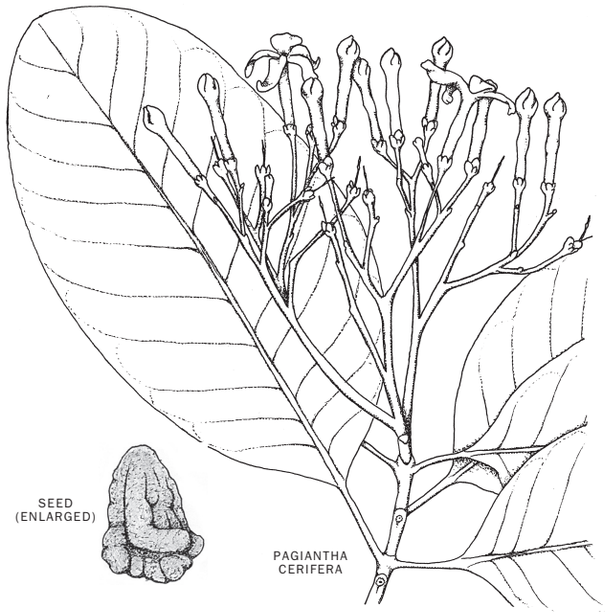
P. pringlei has yielded 0.05% tehuanine [2-methyl-5,6,7-trimethoxy-THIQ], 0.014% tehuanine N-oxide, 0.017% heliamine, lemaireocereine [7,8-dimethoxy-THIQ], weberine [5,6,7,8-tetramethoxy-THIQ; weak MAOI] (Bembenek et al. 1990; Mata & McLaughlin 1980; Pummangura et al. 1982b), weberidine [7-MeO-THIQ], N-methylheliamine (Unger et al. 1980), carnegine and *DMPEA* [tentative] (Trout ed. 1999, citing unpublished work by Crockett & Shulgin).

Pachycereus pecten-aboriginum is a very large tree-like cactus 5-10m tall, with a trunk 1-2m x 30cm, crowned with many erect branches; 10-11 ribs; areoles 1cm diam. or less, extending downwards in narrow grooves, in the flowering ones forming brownish cushions connecting with the areoles below, densely tomentose, greyish except in flowering ones, which are brownish or reddish; spines 8-12, 1-3 central, all short, usually 1(-3)cm long or less, greyish with black tips. Flowers diurnal, 5-7.5cm long; outer perianth segments short, spatulate, purple, succulent; inner ones white, fleshy; tube covered with small scales bearing felt and bristles in their axils; stamens included, very numerous, inserted along throat. Ovary covered with dense soft hairs with only a few or no bristles; style included, with 10 linear stigma-lobes. Fruit 6-7.5cm diam., dry, covered with yellow wool and long yellow bristles; seeds large, black.

Mexico [Chihuahua, Sonora, Colima], lower California (Britton & Rose 1963).

PAGIANTHA

(Apocynaceae)



Pagiantha cerifera *(Panch. et Sébert) Markgraf* **(Tabernaemontana cerifera** *Panch. et Séb.***; Ochrosia novo-caledonica** *Däniker***)**

This small New Caledonian tree is used in indigenous medicine as a charm and violent purgative (Bouiteau 1981).

P. cerifera leaves have yielded *voacangine*, *voacangine* hydroxyindolenine and *ibogaine* (Harmouche et al. 1976). A later study observed 2 different ecotypes of this species, which differed in their chemistry, though were not significantly different botanically. However, it should also be noted that some of the samples were over 20 years old when analysed. The form growing as a small tree, in schistic rock, was harvested in October, 1967 [leaves and fruits] and September, 1983 [trunk bark] from Rivière Tendé; the form growing as a shrubby bush, in peridotitic rock, was harvested in September, 1978 from La Coulée [leaves] and September, 1983 from Rivière Bleue [trunk bark and fruits]. The former type yielded 0.27% alkaloids from leaves [40% *voacangine*, 20% *ibogaine*, 5% *voacangine* hydroxyindolenine], 0.95% from trunk bark [32% *voacamine*, 30% *vobasine*, 6% descarbomethoxy-*voacamine*, 5% methuenine, 0.02% pagisulfine], and 0.6% from fruit [45% *coronaridine*, 29% oxo-3-*coronaridine*, 6% *coronaridine* hydroxyindolenine]. The latter type yielded 0.43% alkaloids from leaves [40% *vobasine*, 8% *ibogaine*, 7% voaphylline, 5% perivine, 3% vallesamine, 3% stemmadenine], 0.6% from trunk bark [18% *vobasine*, 18% methuenine, 10% tabernamine, 7% perivine, 4% olivacine, 2% dihydroellipticine, 0.5% ceridimine, 0.4% pagisulfine, 0.25% ervitsine, 0.25% pericyclivine, 0.1% pagicerine], and 0.25% from fruits [40% *vobasine*, 30% *ibogaine*] (Bert et al. 1989).

Pagiantha cerifera is a small tree or shrubby bush, 4-10m tall, often composed of several stems, slightly ramified, green-yellowish towards summit; bark in 2 distinct parts, external layer suberose, whitish, rugose, internal layer thin and brown. Leaves ovate-lanceolate to elliptic, 11-17 x 5-8cm, rounded or very obtuse towards apex, base cuneiform, coriaceous, margin often briefly reduplicate, central nerve strongly raised beneath, canaliculate above; lateral nerves 8-11 on each side, 10-15mm distant, no tertiary reticulation visible; petiole robust, 8-15mm long; anisophylly discreet. Inflorescences in terminal cymes, with more than 2 later-

al branches; peduncles 4-5cm long, robust; bracts small and caducous; pedicels 10-15mm long, often bearing a bracteole towards the middle; calyx with sepals free almost to the base, broadly oval, apex rounded, ciliate, nerves apparent, often unequal, the largest to 4.5 x 3.3mm, bearing a row of 5-7 glandular appendices at the base of the internal face; corolla white, tube 20-22mm long, very weakly reinflated towards the middle; stamens inserted in inferior part of this bulge, just to the lower-half of the tube, 3mm high, very shortly mucronate to apex, on edge slightly and irregularly lobed, lobes 12-14mm long, ribboned, contorted, overlapping. Ovary and carpels fused; style composed of 2 fused stylodes but remaining distinct; clavoncule cylindrical, weakly dilated and papillose to the base, then attenuated in columns thinner than the style, bearing stigmas at apex. Fruit +- apocarpous at length, syncarpous to the base, rarely hemisyncarpous, with very persistent calyx; mericarps equal, or sometimes very unequal due to one of them aborting, ovoid, shortly apiculate to apex, 4-5cm long, 2.5cm wide, 2cm thick; seeds with deep ventral furrows, on the back adorned with broken lines of nipples, but without furrows; albumen ruminated; embryo straight, cotyledons elliptic, rounded to the base.

New Caledonia (Boiteau 1981).

PANAEOLUS [including COPELANDIA and PANAEOLINA]

(Agaricaceae/Coprinaceae)

Panaeolus africanus *Ola'h*

Panaeolus antillarum *(Fr.) Dennis* **(P. ovatus** *(Cke. et Mass.) Sacc.***; P. phalaeranum** *(Fr.) Quélet***; P. sepulcralis** *Berk.***)** – jingasatakemodoki

Panaeolus ater *(Lange) Kühner et Romagnesi* **(P. fimicola** *Fr.***)**

Panaeolus castaneifolia *(Murrill) Gerhardt* **(P. castaneifolia** *(Murr.) Bon.***; P. castaneifolius** *(Murr.) A.H. Sm.***)**

Panaeolus goosensiae *Beeli*

Panaeolus microsporus *Ola'h et Cailleux*

Panaeolus olivaceus *Möller*

Panaeolus rubricaulis *Petch* **(P. campanuloides** *Guzmán et K. Yokoy.***)**

Panaeolus semiovatus *(With. ex Fr.) Lundell et Nannf.* **(P. semiovatus** *(Sow. ex Fr.) Lund. et Nannf.***; P. separatus** *(L. ex Fr.) Gill.***; P. separatus** *(L. ex Duby) Wünsche***)** – jingasatake, phak timu

Panaeolus sphinctrinus *(Fr.) Quélet* **(P. campanulatus** *(Fr.) Quél.***; P. campanulatus var. sphinctrinus** *(Fr.) Bres.***; P. papilionaceus** *(Bull. ex Fr.) Quél.***; P. retirugis** *(Fr.) Quél.***; Agaricus callosus** *Fr.***)** – waraitake ['laughing mushroom']?, maitake ['dancing mushroom']?, odoritake ['jumping mushroom']?, hikagetake

Panaeolus subbalteatus *(Berk. et Broome) Sacc.* **(P. venenosus** *Murrill***)** – belted-cap Panaeolus, weed Panaeolus, poisonous Panaeolus, senbonsaigyogasa, gold tops, gold caps

Panaeolus venezolanus *Guzmán* **(P. annulatus** *Natarajan et Raman***)**

Copelandia affinis *Horak* **(P. affinis** *(Horak) Gerhardt***)**

Copelandia anomala *Murrill* **(P. anomalus** *(Murr.) Sacc. et Trotter***)** – gold tops, gold caps

Copelandia bispora *(Malencon et Bertault) Sing. et Weeks* **(C. papilionacea var. bispora** *Malen. et Bert.***; P. bisporus** *(Malen. et Bert.) Gerhardt***; P. cyanescens var. bisporus** *(Malen. et Bert.) Moreno et Esteve-Raven.***)** – gold tops, gold caps

Copelandia cambodginiensis *(Ola'h et Heim) Sing. et Weeks* **(P. cambodginiensis** *Ola'h et Heim***)** – gold tops, gold caps

Copelandia chlorocystis *Sing. et Weeks* **(P. chlorocystis** *(Sing. et Weeks) Gerhardt***)**

Copelandia cyanescens *(Berk. et Br.) Sing.* **(C. papilionacea** *(Bull. ex Fr.) Bres.***; P. cyanescens** *(Berk. et Br.) Sacc.***; P. papilionaceus** *sensu Bres.***)** – blue meanies, hed keequai ['mushroom which appears after water buffalo defecates'], cone-heads, gold tops, pan cyan

Copelandia lentisporus *(Gerhardt) Guzmán* **(P. lentisporus** *Gerhardt***)**

Copelandia mexicana *Guzmán*

Copelandia tirunelveliensis *Natarajan et Raman* **(P. tirunelveliensis** *(Natarajan et Raman) Gerhardt***)**

Copelandia tropicalis *(Ola'h) Sing. et Weeks* **(P. tropicalis** *Ola'h***)** – gold tops, gold caps

Copelandia westii *(Murr.) Sing.*

Panaeolina foenisecii *(Fr.) Maire* **(Panaeolus foenisecii** *(Fr.) Kühner***; Psathyrella foenisecii** *(Fr.) Smith***; Psilocybe foenisecii** *(Pers. ex Fr.) Quél.***; Agaricus foenisecii** *Pers. ex Fr.***)** – haymaker's toadstool, haymaker's mushroom

Panaeolina indica *Sathe et J.T. Daniel* **(P. microsperma** *Natarajan et Raman***)**

Panaeolina rhombisperma *Hongo*

Panaeolina sagarae *Hongo*

The 'laughing mushroom' or 'waraitake' [as well as the 'maitake' and 'odoritake'], which has caused historic joyous inebriations in Japan, is thought to have been Panaeolus sphinctrinus [as P. papilionaceus], though this identification may be in error [see also **Gymnopilus**]. It would seem more likely that Copelandia cyanescens or a similar species were involved; C. cyanescens had previously been known as P. papilionaceus under a different author. Of the waraitake, it is said "people who eat of this mushroom get drunk. They may become extremely excited and dance and sing or see various hallucinations" (Sanford 1972). Portuguese witches were reported to have used P. papilionaceus for magical enchantments (Graves 1970). It has been proposed that the mushroom thought to have been used at the Lesser Mysteries of Eleusis [see **Claviceps**] may have been a Panaeolus sp. [see also **Amanita**]. In some areas of modern Greece, locals know of unidentified 'hallucinogenic' mushrooms which they refer to as 'crazy mushrooms'. They are not regarded as poisonous, but they are known to be "inebriating like wine, though in an entirely different way" (Samorini 2001; Wasson et al. 1978).

P. sphinctrinus [as P. campanulatus var. sphinctrinus] was collected as an example of 'teonanácatl' [see **Psilocybe**] in Mexico (Schultes 1939; Wasson 1963), but the authenticity of the claimed use of this mushroom in Oaxaca is under question, as is its psychoactivity. The Mexican shamanic use of P. ater has also been reported (Wasson 1961). Recently, it was discovered in Nepal that some Kirati shamans eat [or inhale as an ingredient of a compound snuff] a Panaeolus sp. known as 'gobar chyau' for shamanic travel, or as one shaman related, "We take this mushroom only when it is very important to fight against demons. We roast it and take it with salt in order to neutralise its poison. We take it for medicine and knowledge". P. semiovatus may also be so used (Müller-Ebeling et al. 2002).

C. cyanescens is consumed and sold to tourists and restaurants on the islands of Koh Samui and Koh Pha-Ngan, Thailand; this is also known to occur in other areas of Thailand, Indonesia [Java, Sumatra], Samoa, Bali and the Philippines to some extent. They are cultivated on dung in rice paddies, but also occur spontaneously in dung of the cattle Bos guarus, B. indicus, B. sundaicus and the domestic water-buffalo Bubalus bubalis, as well as the horse [Equus caballus]. Other species used in these areas include P. ater [Indonesia], C. cambodginiensis [Kampuchea] and C. tropicalis [Philippines, Kampuchea] [see also **Psilocybe**] (Allen & Gartz 1997; Allen & Merlin 1992). Children in Koh Samui have warned researchers that P. antillarum was 'antaray' [dangerous] (Gartz et al. 1994). Similar practices of sale of C. cyanescens to tourists have been observed in Jamaica (Allen & Gartz 1997), and this species has also become popular in Peru (Allen 1998).

In Hawaii, many species have been used 'recreationally' in non-native practices since the late 1960's/early 1970's – including C. anomala, C. bispora, C. cambodginiensis, C. cyanescens, P. subbalteatus and C. tropicalis. This use is thought to have been introduced by Australian surfers, and has even been noted amongst military personnel on the islands. No traditional use of these fungi has been uncovered, though one elderly native man from Maui admitted to consuming psychedelic mushrooms in the 1940's to exorcise evil spirits; he knew of no-one else who did this (Allen 1998; Merlin & Allen 1993).

P. subbalteatus is well-known as a weed of commercial mushroom [Agaricus bisporus] crops (Singer & Smith 1958), and is used as a psychedelic in parts of e. & s. USA, as well as in other countries in which it grows. One early recorded experiment of consumption of 1.5g [in the name of science] resulted in "a strong favourable and euphoriant effect", deemed to be more desirable than the effects of **Psilocybe** caerulescens, probably due to the great differences in potency. Consumption of 0.5-1g oven-dried specimens elicited a mild and pleasant inebriation, accompanied by some dizziness, sweating, and slight mydriasis. In another early experiment, twice this amount of P. subbalteatus was required by the subject to perceive effects, consisting of a 'tranquil inebriation' (Stein 1959, 1960; Stein et al. 1959). C. cyanescens and P. subbalteatus are also cultivated in the US and other countries by underground mycologists (Stamets & Chilton 1983).

P. sphinctrinus has also sometimes been consumed, with 40-250 specimens being ingested to produce the hoped-for effects. According to literature reports, P. sphinctrinus consumption has led to a wide history of documented human intoxications in Europe and America, though species identification was most likely in error. Such early reports are notorious for the hasty identifications of mushroom species alleged to have caused inebriations; the identifications have usually been based on presumption rather than microscopic analysis. Most authorities do not consider this species to be psychoactive. It has been claimed that individual sensitivity varies, and moderate quantities produce no effect. Even "thrifty farmers taking advantage of a chance to get drunk for nothing" have taken it in New England. One report of ingestion of 2g parboiled specimens resulted in "noticeable intoxication, but no hallucinosis" (Allen 1997a; Beug & Bigwood 1982; Guzmán et al. 1976; Pollock 1976; Sanford 1972; Weil 1977b). One researcher ate 6 dry specimens [0.8g], as P. campanulatus, and experienced no effects of any kind (Tyler & Malone 1960). Another man, from New Jersey, conducted an experiment with P. papilionaceus as food [probably actually another, *psilocybin*-containing species], not realising what he and his wife were in for. In his own words – "Last Sunday morning I had great difficulty in finding any mushrooms whatever, so I

was happy when I finally came across a few specimens of Coprinus [see *Endnotes*] mixed in with a few of Panaeolus papilionaceus. I have never tried this last mushroom, but, as Mr. McIlvaine says that in small quantities they are harmless and contain a very mild intoxicant only, I did not hesitate to let them join the Coprini in the pot. The results, however, were very startling." The man ate "five times as much" as his wife, who ate approx. 3 caps [it was not stated what portion of the caps were from the purported P. papilionaceus]. Curiously, whilst the lady felt effects within 5-6 min., the man did not note any effects until 1-2 hrs later. The experience was compared to "violent opium poisoning" [see **Papaver**], which the couple believed they knew about from reading the visionary experiences described in De Quincy's "Confessions of an English Opium-Eater". All effects subsided within 4-5 hrs (Fries 1916).

There has been a report of accidental mushroom-intoxication in France, believed to have involved C. cyanescens or a similar species which had become naturalised. This species normally occurs in tropical areas. Specimens of the Copelandia sp. were shown to contain 0.15-0.2% *psilocybin*, and similar quantities of *tryptophan*; these were also present in the mycelium (Heim et al. 1966).

C. cyanescens is also used and highly-prized by some in n.e. Australia and South Australia, where specimens are known as 'blue meanies', referring to the strong bluing reaction of this species [and to the characters of the same name in 'Yellow Submarine']; its potency rivals many of the commonly used **Psilocybe** mushrooms. Some people do not like elements of the effects, however, and prefer **Psilocybe**. P. antillarum may also have been used in Australia for its psychotropic properties, and there are reports from earlier last century of intoxications produced by P. ovatus [a synonym of P. antillarum] in NSW, Australia, though identification may have been in error (pers. obs.; Aberdeen & Jones 1958; Low 1985; Southcott 1974; Trotter 1944).

A psychedelic intoxication from P. foenisecii was reported from Adelaide [S. Australia], in a 2-year-old girl who had eaten the fungi from her parent's lawn (Southcott 1974). This species has been implicated in several other incidents where children have become intoxicated. Intentional intoxications have also been reported from the UK; in one case, 3 young men each ate 20-30 fresh specimens and experienced psychedelic effects (Cooles 1980). It has been suspected by some that the identity of the mushrooms was in error (Allen & Merlin 1993), possibly involving **Psilocybe** semilanceata. A friend has also consumed P. foenisecii on numerous occasions [from 3 widely separate regions of the US, and 3 widely separate regions of Australia], with mild psychotropic effects experienced. He reported that large amounts must be consumed for any effects, and that the substrate in which the fungi are growing may affect the chemical composition. Based on these experiments, he believes that "apparent *psilocybin* concentration is directly proportional to the concentration and freshness of cow/horse manure in the substrate, and that it is most often found apparently in symbiosis with domestic fescue-type thinblade lawns" [see **Festuca**] (Turney pers. comm.). Most ingestions of this species - even in very large amounts - result in diarrhoea but no noteworthy CNS effects (pers. comms.).

As some researchers now insist that P. foenisecii is 'inactive' and does not ever contain *psilocybin* or *psilocin* (Allen & Merlin 1993), there is still some confusion about this species. Although the content of *psilocybin* and/or *psilocin* is in doubt, and is usually not found, it is certain that this species is occasionally capable of exerting mild psychoactive effects, with particular batches consumed in large enough quantities [over 50g fresh]. The assumption that *tryptophan* and *5-hydroxytryptophan* might be responsible for this is confused by the low yields of these compounds from P. foenisecii [see below], but as hardly anyone has actually quantified these chemicals in this species we know hardly anything about the true range of concentrations found naturally. Further research is needed to clarify this contentious issue.

Panaeolus spp. generally are high in urea content, most so when sporulating; the urea is mostly concentrated in the caps (Stijve 1992).

Panaeolus acuminatus [P. rickenii] has yielded only 0.016% *serotonin* [*5-HT*], 0.066% *5-hydroxytryptophan* [*5-HTP*] and 0.029% *tryptophan*, as well as 5-OH-indoleacetic acid (Stamets 1996; Tyler & Smith 1964); HPLC showed a compound with retention time similar to that of *psilocybin*, but with different response ratios (Christiansen & Rasmussen 1983). Czech specimens were found to contain no detectable *psilocybin* or *psilocin* (Stríbrný et al. 2003).

P. africanus contains *psilocybin* and *psilocin* in variable amounts; it grows on elephant and hippo dung (Stamets 1996). It has been considered to be '*psilocybin*-latent' (Ola'h 1968).

P. antillarum is generally considered to be inactive, containing no *psilocin* or *psilocybin* [though Brazilian specimens yielded 0.035% *5-HT*] (Beug & Bigwood 1982; Stijve & de Meijer 1993), but a collection from Koh Samui, Thailand, yielded less than 0.01% each of *psilocin*, *psilocybin* and *baeocystin*, 0.035% *tryptophan*, 0.015% *5-HT*, less than 0.002% *tryptamine*, and 2.8% urea (Allen & Merlin 1992); Japanese specimens yielded 0.045-0.083% *psilocybin* (Kusano et al. 1986). It is also found in Australia in dung [SA, NSW, Qld] (Young 1989).

P. ater contained small amounts of *psilocybin* and/or *psilocin*, in some samples (Ola'h 1968; Stamets 1996); Sardinian specimens were found to contain 0.14% *psilocybin* and 0.03% *psilocin* (Ballero & Contu 1998); others have found none, only small amounts of *5-HT*, urea (Gurevich 1993) and *tryptamine* (Wurst et al. 1992). Widespread in Africa, Europe and the Americas (Stamets 1996). It has been recorded in dung from Melbourne and Port Phillip [Vic., Australia], but has not been collected again there formally since the 19th century (Young 1989).

P. castaneifolia has been considered to be '*psilocybin*-latent' (Ola'h 1968); some specimens have been shown to contain *psilocybin* and/or *psilocin* in small amounts (Stamets 1996).

P. fontinalis has yielded *tryptamine*, *tryptophan*, *5-HT* and *5-HTP* (Tyler & Smith 1964).

P. goosensiae from Hawaii yielded less than 0.01% *psilocin/psilocybin*, less than 0.005% *5-HTP*, 0.01% *5-HT* and 0.6% urea (Merlin & Allen 1993), though a later work states that this species is not psychoactive (Allen 1998). No explanation is offered for the discrepancy; perhaps the species used in the previously mentioned analysis had been incorrectly identified, or perhaps it is in reference to the low potency.

P. guttulatus has been found to contain *tryptamine* and *5-HT* (Wurst et al. 2002).

P. microsporus cultured specimens have yielded *psilocybin* (Allen et al. 1992); this species has been considered to be '*psilocybin*-latent' (Ola'h 1968).

P. nirimbii has been found to contain *5-HT* (Wurst et al. 2002).

P. olivaceus yielded 0.005% *psilocybin* from 1 out of 3 fresh Finnish samples (Ohenoja et al. 1987).

P. rubricaulis has been reported to contain *psilocybin* (Guzmán et al. 2000).

P. semiovatus is generally considered to contain no *psilocin* or *psilocybin* (Beug & Bigwood 1982; Ola'h 1968), but Japanese specimens yielded 0.0007-0.001% *psilocybin* (Kusano et al. 1986); *5-HT*, *tryptophan* and *5-HTP* have also been found (Tyler & Smith 1964).

P. sphinctrinus has been considered to be '*psilocybin*-latent', or, as P. campanulatus and P. retirugis, 'non-psilocybian' (Ola'h 1968). Many specimens have been shown to contain *tryptophan*, *5-HT*, *5-HTP*, 5-OH-indoleacetic acid and urea, but only some strains ['RP1', some strains from Quebec, and some Italian & Japanese specimens] have been shown to contain *psilocin* and sometimes *psilocybin* as well. One Italian collection reportedly yielded 0.08% *psilocybin* (Gurevich 1993; Ott & Guzmán 1976; Pollock 1976; Tyler & Groger 1964b; Tyler & Smith 1964); specimens from Sardinia [Italy] yielded 0.11% *psilocybin* and 0.008% *psilocin*; specimens identified as P. retirugis [generally considered a synonym] yielded 0.12% *psilocybin* and 0.05% *psilocin*; specimens identified as P. papilionaceus [synonymy less certain – see above] yielded 0.07% *psilocybin* and 0.04% *psilocin* (Ballero & Contu 1998). Japanese specimens have yielded 0.014-0.017% *psilocybin*, and as P. campanulatus, 0.04-0.05% *psilocybin* (Kusano et al. 1986). As P. campanulatus, both cultivated and wild specimens were shown to contain citrulline, as well as *tryptophan*, *5-HT*, *5-HTP*, urea, what was possibly *choline*, and 4 unidentified compounds. These researchers believed muscarine to be present in small amounts (Tyler & Malone 1960), though the evidence offered to support this assumption was grossly insufficient. Mycelial culture did not yield any detectable levels of indoles (Neal et al. 1968). In Australia, it has been found [usually on horse dung] in WA, SA, Vic., NSW and Qld (Young 1989).

P. subbalteatus from Europe yielded 0.01-0.7% *psilocybin*, 0.004% *psilocin* [in one sample only] and 0.008-0.46% *baeocystin*, as well as 0.08-0.3% *5-HT*, small amounts of *5-HTP*, *tryptamine* and *tryptophan*, and urea. Some samples contained more *psilocybin* in caps than in stems, though others were +- equipotent in this regard. Highest *psilocybin* and *baeocystin* content was in smaller specimens. Russian samples yielded [from the caps] 0.05-0.36% *psilocybin*, up to 0.11% *baeocystin*, *5-HT*, and large amounts of urea; stems yielded 0.05-0.17% *psilocybin*, traces of *baeocystin*, and small amounts of *5-HT*, *5-HTP* and urea (Gartz 1989b; Gurevich 1993, 1995; Ohenoja et al. 1987; Stijve & Kuyper 1985; Tyler & Smith 1964). Sardinian specimens yielded 0.31% *psilocybin* and 0.11% *psilocin* (Ballero & Contu 1998). Brazilian specimens yielded 0.033-0.08% *psilocybin*, no *psilocin*, 0.058-0.097% *5-HT* and 0.1-0.21% *5-HTP* (Stijve & de Meijer 1993). Japanese specimens yielded 0.061-1.46% *psilocybin* (Kusano et al. 1986). Samples from Pacific n.w. US yielded 0.16-0.65% *psilocybin*, and no *psilocin* (Beug & Bigwood 1982). In US samples of sometimes considerable age, only 0-0.005% *baeocystin* was detected (Repke et al. 1977). Preliminary tests showed *psilocybin* and/or *psilocin* to also be present in the sclerotia (Singer & Smith 1958). One early preliminary analysis could not detect any *psilocybin*; 4 unidentified compounds were detected, including one which appeared to be a 4-OH-indole compound, but was not identical to *psilocybin* (Stein et al. 1959). Later, cultivated mycelium was shown to contain 0.07% *psilocybin*, 0.1% *5-HT*, 0.2% *tryptophan* and traces of *tryptamine* (Gartz 1989b). About 30g fresh, or 7-20 specimens, may constitute a dose (Allen 1998). Though this species has been claimed to definitely occur in Australia (Allen pers. comm.), its presence is presently considered highly suspect and was not able to be verified (Young 1989).

P. texensis has yielded *5-HT* and *5-HTP* (Tyler & Smith 1964).

P. venezolanus has been reported to contain *psilocybin* (Guzmán et al. 2000).

C. affinis has been reported to contain *psilocybin* (Guzmán et al. 2000).

C. bispora from Switzerland has yielded 0.41% *psilocin* and traces of *psilocybin* from dried specimens (Senn-Irlet et al. 1999); this species loses c.50% of its potency when dried. From 7-10 fresh specimens may constitute a dose. It is often found growing with C. cyanescens in Hawaii (Allen 1998).

C. cambodginiensis from Hawaii yielded 0.3-0.6% *psilocin*, 0.13-0.55% *psilocybin*, less than 0.005-0.02% *baeocystin*, less than 0.005-0.008% *tryptophan*, 0.005% *tryptamine* and 0.1-0.56% urea (Merlin & Allen 1993). From 7-10 fresh specimens may constitute a dose (Allen 1998).

C. chlorocystis yielded 0.46% *psilocybin* and 0.29% *psilocin*, as well as a compound which is probably *baeocystin*. It grows in the Okeechobee region of Florida on rich sod in grass (Weeks et al. 1979).

C. cyanescens from Koh Samui, Thailand yielded 0.4-1.05% *psilocin*, less than 0.025% each of *psilocybin* and *baeocystin*, less than 0.02% *tryptophan*, 0.026-0.033% *5-HT*, 0.002-0.008% *tryptamine* and 2-3.3% urea (Allen & Merlin 1992). Australian samples [from Qld] yielded 0.025-0.71% *psilocin*, <0.012-0.04% *psilocybin*, <0.01% *baeocystin*, <0.01-0.03% *tryptophan*, <0.004-0.02% *tryptamine*, 0.023-0.45% *5-HT* and 0.2-4.5% urea; Hawaiian samples yielded 0.04-1.3% *psilocin*, 0.01-0.73% *psilocybin*, <0.005-0.035% *baeocystin*, 0.006-0.02% *tryptophan*, <0.005% *tryptamine*, 0.005-0.24% *5-HT* and 0.07-3% urea. Caps and stems contained +- even proportions of *psilocin*, but stems contained 3x more *psilocybin*; *5-HT* is concentrated in the caps (Stijve 1992; Stijve & de Meijer 1993). From 7-10 fresh specimens may constitute a dose (Allen 1998). Using Hawaiian samples of C. cyanescens [containing 0.6% *psilocin*, 0.2% *psilocybin*], 1g of dried, powdered mushroom has been sufficient to cause strong psychedelic effects (Stijve 1992).

C. lentisporus has been reported to contain *psilocybin* (Guzmán et al. 2000).

C. tirunelveliensis has been reported to contain *psilocybin* (Guzmán et al. 2000).

C. tropicalis contains moderate to high levels of *psilocybin* and/or *psilocin* (Ola'h 1968; Stamets 1996). 7-10 fresh specimens may constitute a dose (Allen 1998).

C. mexicana and C. westii are presumed to be active due to their bluing reaction when bruised (Ott 1993). Some consider C. westii a synonym of C. cyanescens (Guzmán et al. 2000).

Panaeolina foenisecii from Indiana yielded 0.17% *psilocybin* (Robbers et al. 1969), though many samples from other locations contained no *psilocybin* or *psilocin* (Beug & Bigwood 1982; Mantle & Waight 1969; Ott & Guzmán 1976; Stamets 1996; Stijve & de Meijer 1993). Robbers et al. (1969) only noted the absence of *psilocybin* from collections more than 6 years old. In one test, only 2 out of 19 dry Finnish samples yielded 0.03% *psilocybin* each (Ohenoja et al. 1987). Sardinian specimens yielded 0.06% *psilocybin* and 0.04% *psilocin* (Ballero & Contu 1998). Australian specimens yielded *psilocybin* but no *psilocin* (Anastos et al. 2006). The species has also yielded *tryptamine*, *tryptophan*, *5-HT*, *5-HTP* and 5-OH-indoleacetic acid (Robbers et al. 1969; Tyler & Smith 1964). Swiss specimens yielded 0.22-0.5% *5-HT* and 0.33-0.45% *5-HTP*, but no *psilocybin*, *psilocin* or *baeocystin*, similarly to Brazilian specimens which yielded only 0.25% *5-HT* and 0.58% *5-HTP* (Stijve & de Meijer 1993). It is also found in grass in southern Australia; some Australian samples have not tested positive for the presence of *psilocybin* (Young 1989), although one sample did, yielding 0.068-0.073% *psilocybin* and no *psilocin* (Anastos et al. 2006). It is now commonly considered to be inactive (Allen & Merlin 1993; Allen et al. 1992), after long being considered '*psilocybin*-latent' – that is, *psilocybin* is sometimes found, sometimes not (Ola'h 1968), possibly dependent on substrate. It is likely in some cases that positive laboratory assays have relied on inadequate identification of the compounds present, but it is questionable to assume that this applies to all positive results.

Panaeolina indica, P. rhombisperma, and P. sagarae have been reported to be psychoactive (Guzmán et al. 2000).

Copelandia cyanescens has a cap 1-3.5(-4)cm across, hemispheric to campanulate to convex at maturity; margin initially translucent-striate when wet, incurved only in young fruiting bodies, soon opaque and decurved, expanding in age, becoming flattened and often split and irregular at maturity; light brown at first, becoming pallid grey or nearly white, with centre remaining tawny brown, soon fading; cap cracking horizontally in age with irregular fractures; flesh readily bruising bluish. Stem (65-)85-115mm x 1.5-3(-4)mm, equal to bulbous at base, tubular; often greyish towards apex, pale yellowish overall, flesh coloured to light brown towards base; surface covered with fine fibrillose flecks, which soon disappear; partial veil absent; flesh readily bruising bluish. Gills adnexed-adnate, close, thin, with 2-3 tiers of intermittent gills; mottled greyish-black at maturity. Spores black, 12-14(-16) x 7.5-11(-12)µ, opaque, without granulations, lens-shaped to slightly hexagonal; basidia (2-)4-spored; pleurocystidia fusoid-ventricose, narrowing to acute apex, 30-60(-80) x 12-17(-25)µ; cheilocystidia 11-15 x 3-5(-6)µ, +- cylindrical, hyaline and thin-walled.

Scattered to gregarious in dung in pastures and fields; US [Hawaii, Louisiana, Florida], Mexico, Brazil, Bolivia, Philippines, Thailand, Australia [NT, Qld, NSW (east coast, north of Sydney)], and occasionally near Menton, France; also in many other semitropical zones (Stamets 1996; Young 1989; Young, T. 1994). Also recently confirmed growing in dung in cow pastures near Lorne, Victoria [Australia] (Bluemeanie pers. comm. 2002).

Most Panaeolus spp. and Copelandia spp. appear in spring or rainy seasons; most are coprophilic [dung-loving] and grow directly on dung [usually of cattle or horses]; some spp. grow in soil or in grassy areas [such as P. ater, P. castaneifolia and P. foenisecii]. Check your local mushroom guide for details, as some of these mushrooms are quite widespread.

Some authors and mycologists maintain Panaeolus campanulatus, P. papilionaceus and P. retirugis as separate species to P. sphinctrinus. The choice to treat them here as equivalent, as did Stamets (1996), is based on convenience rather than agreement with any particular taxonomic argument. Regardless, these species are very similar and variable in appearance.

PANAX

(Araliaceae)

Panax bipinnatifidum *Seem.* **(P. japonica var. bipinnatifidus** *(Seem.) Wu et Feng***; P. pseudoginseng ssp. himalaicas var. bipinnatifidus** *(Seem.) Li***)** – yü-yeh chu-chieh sêng ['feather-leaf bamboo ginseng'], double cut-leaved ginseng

Panax ginseng *C.A. Meyer* – jên-sêng, ren-shen, nin-sin, ginseng, chosen ninjin, korai ninjin, otane ninjin

Panax japonicum *C.A. Meyer* **(P. pseudoginseng ssp. japonicus** *Hara***)** – chu-chieh sêng ['bamboo ginseng'], Japanese ginseng, chikusetsu ginseng, chikusetsu ninjin, tochiba ninjin

Panax major *(Burkill) Ting* – ta-yeh san ch'i

Panax notoginseng *(Burkill) F.H. Chen* – san-ch'i ginseng

Panax pseudoginseng *Wall.* **(Aralia quinquefolia var. pseudoginseng** *(Wall.) Burkill***)** – san-ch'i, jên-sêng san ch'i, chin-pu-huan, han-san-ch'i, Himalayan ginseng

Panax quinquefolia *L.* **(P. quinquefolium** *L.***)** – American ginseng, hsi-yang-sêng, hua-ch'i-sêng, garent-oguen, a tali kuli

Panax stipuleanatus *H.T. Tsai et K.M. Feng* – pin-bin-san-chek, ye san qi, tu san qi, bai san qi, zhu jie qi

Panax trifolius *C.A. Meyer* – chikusetsu-ninjin, satsuma-ninjin, dwarf ginseng, groundnut

Panax zingiberensis *C.Y. Wu et K.M. Feng* – san-qi, jiang zhuang san qi, ginger ginseng

'Ginseng' [usually referring to P. ginseng], the revered root of the Orient, is believed to be the crystallised "essence of heaven and earth in the form of a man". The anthropomorphic form sometimes taken by older ginseng roots helped give rise to the view that they had potent medicinal properties, a view borne out in experience and modern pharmacological testing. The root has been reputed to "support the five visceral organs, calm the nerves, tranquillise the mind, stop convulsions, expunge evil spirits, clear the eyes, and improve the memory", as well as increasing longevity with daily use. Since ancient times in China, even a single wild ginseng root ['yeh-shan-sêng'] has fetched a very high price – the older and more anthropomorphic the root, the higher the fee. It is possible to obtain roots from plants hundreds of years old. Severe danger lay in store for the ginseng-collectors [known in China as 'va-pang-suis'], as the plant grew deep in forests in virtually inaccessible terrain, and the collectors also had to contend with bandits and wild animals. Today, the wild plant is virtually extinct, but is widely cultivated ['yuan-sêng'] in China, Japan, Korea and Russia. Although considered 'king of herbs' in TCM, the properties of ginseng were long doubted in the west, until recent scientific verification. Work in the west was slow as researchers were looking for alkaloids and other chemicals with specific, individual medicinal activities; it is now known that the compounds present in ginseng work synergistically, and present their pharmacological effects in a manner different to traditional western medicines; that is, the herb works as an adaptogen (Brekhman & Dardymov 1969b; Fulder 1993; Gillis 1997; Hu 1976; Huang 1993; Kimmens ed. 1975). In rural Japan, P. japonicum is used similarly to P. ginseng as a medicinal tonic for a wide array of ills, although contraindicated for pregnant women (Brussell 2004).

P. quinquefolia has been used by native North Americans to "strengthen mental processes", and to treat coughs, fever and headache. In the early 1700's, Europeans discovered the species growing in Canada, in similar habitat to P. ginseng in Asia. Shortly after, the trade in American ginseng exploded, as settlers wild-harvested the plant [which they called 'sang'] for export. Many of these people did not even use the herb themselves, or have any belief in its virtues, yet they knew that Chinese people would pay good money for it. As the boom in ginseng trade grew to epic proportions, plants were often harvested regardless of season or age, and in great quantity, wherever they could be found by those seeking a quick profit.

By the early 1900's, wild P. quinquefolia was virtually non-existent. Due to the poor harvesting practices and often inappropriate preparation used [eg. hasty drying], much of the later product was rejected anyway, by the Chinese customers. This is a prime historic example of the destructive abuse of a plant. Early attempts at establishing a domestic cultivation industry quickly failed due to a combination of pests and diseases, and the delicate growing requirements of the plants. Today, with greater experience, the species is again more widely cultivated, both in N. America and China, where its use has been adopted in TCM (Fulder 1993; Huang 1993; Kimmens ed. 1975).

Apparently ginseng has been used in folk medicine, alone or with other herbs, to treat opium addiction [see **Papaver**]. The effectiveness of this has been recently reflected in the laboratory; the ginsenosides of ginseng have been shown to have weak analgesic effects, and to prevent *morphine* tolerance in rats (Choi et al. 2000).

Ginseng on the marketplace comes in many varieties. The most desirable is usually considered to be red ginseng or Korean red ginseng ['kaoli-sêng' or 'hung-sêng'], which is the root of P. ginseng prepared by steaming the cleaned root for 3 hours prior to drying it in the sun or over a low fire. The more commonly available white ginseng is also from P. ginseng, but is of a pale yellowish-white colour, and is prepared by bleaching the cleaned roots with sulphur gas before sun-drying. Sometimes this process is taken further to produce sugared ginseng ['t'ang-sêng'], in which case the roots are next soaked in boiling water for 3-7 mins, before being pricked with needles in vertical and horizontal rows, soaked in a strong sugar-syrup for 10-12 hrs, and sun-dried. The last three points are repeated another 3 times before t'ang-sêng is considered ready. Chinese herbalists usually sell ginseng in thin slices – as the dried root is very hard, it must have its 'head' removed and be steamed to soften it for slicing. White ginseng may simply be wrapped in a moist towel for softening. Samples with a broad cross-section and a yellowish-brown colour are of higher quality than small, pale samples. Small, lateral rootlets are usually used separately to the main root, and are known as 'whiskers' ['hsü'], with various prefixes noting their grade and the manner in which they were prepared. These parts are less potent compared to the main root, and are usually used to constitute less-expensive ginseng products. The root hairs do sometimes contain higher levels of active compounds than the main root [see below], but the makeup is less diverse and thus they show a narrower profile of therapeutic activity. Other parts of the plant can also be used, and share some of the properties of the root.

The next most-used species are P. pseudoginseng and P. quinquefolia, which have similar but less-varied medicinal properties, and are cheaper – the latter, however, has shown greater potency in modulating neuronal activity than the Chinese species. Other species listed above are used locally as tonics, though not as effective overall as P. ginseng. Ginseng may be taken regularly without side-effects in the majority of people, though breaks of 1-2 months are recommended after 1 month of continuous [ie. twice daily] use. It may be used regularly without breaks by the elderly or the chronically ill. More should be taken during the winter, though it should not be taken if suffering from a cold, flu or lung infection. Some of ginseng's actions are enhanced by combining it with vitamin C [ascorbic acid]. It is considered incompatible with some metal utensils, as well as opiates, dairy products, tea [see **Camellia**] and coffee [see **Coffea**]. Ginseng may be decocted [traditionally in a silver vessel], though it is more convenient to simply chew and suck on several slices of the root. Effects are fairly rapid via this route, and are thus suitable for when one may need a cognitive and energy boost for a demanding task. In pharmacies and health shops, ginseng is usually available in the form of tablets, capsules or alcoholic extracts. The strongest preparations are often in the form of thick molasses-like extracts (Chuang et al. 1995; Fulder 1993; Hu 1976; Huang 1993; pers. obs.). Ginseng has been used as a tea by **Cannabis**-smokers to soothe the throat and 'clear the head' (Gottlieb 1993). Ginseng leaf tea is available in some Chinese supermarkets in England, claimed on the packet label to 'raise the spirits' (theobromus pers. comm.).

P. ginseng is anxiolytic; stimulates the immune system; regulates the CNS; relieves fatigue; enhances memory, learning, alertness and other cognitive functions; increases cerebral circulation; prevents or compensates for damage to the nervous and endocrine systems caused by stress; inhibits uptake of *dopamine*, *GABA*, *glutamate*, *norepinephrine* and *serotonin* in rat brain; increases rate of alcohol metabolism; acts as an aphrodisiac; stimulates liver function, including synthesis of RNA, DNA and vital proteins; strengthens the heart; helps prevent and heal stomach ulcers; balances hormone activity, protects and stimulates adrenal function; counteracts intoxication, and helps relieve hangover; is an antioxidant and free-radical scavenger; helps heal deformities of the cornea, especially clouding; regulates blood-sugar, blood pressure, and red and white blood-cell count according to the body's need; and shows some antitumour and anticancer activity in humans. It should not be combined with the pharmaceutical drug phenelzine, as headaches and tremor may result. P. notoginseng root has been used as a haemostatic, analgesic, antiinflammatory and tonic. P. zingiberensis root has been used as an analgesic and haemostatic; it has been shown to increase coronary blood flow, reduce blood pressure, and reduce the oxygen consumption of heart tissue. Occasional side-effects such as dry mouth, nausea, vomiting, nervousness, insomnia, and high skin temperature have been observed from ginseng use or abuse (Attele et al. 1999; Bhattacharya et al. 1991b; Brekhman & Dardymov 1969b; Fugh-Berman 2000; Fulder 1993; Gillis 1997; Hsu et al. 1986; Huang 1993).

Ginseng is completely safe in practical amounts. It has been estimated that a human lethal dose may be 2kg of root consumed at one sitting – this is 1,000-5,000 times the effective dose (Fulder 1993). A human fatality has been reported following consumption of 500ml of a 3% ginseng tincture, though the alcohol content of that dose would have been high (Bensky & Gamble 1993). Excessive use can cause adverse symptoms, however, such as excessive stimulation, insomnia, hypertension, headache, dizziness and itching (Gillis 1997; Huang 1993; Siegel 1979). Do not take continuously for more than 6 weeks at a time. Should not be taken with *caffeine*, or by pregnant women (Chevallier 1996). Some women may experience heavy and painful periods with regular ginseng consumption (theobromus pers. comm.).

P. ginseng root contains c.1-4.4% glycosidal triterpene steroid saponins called ginsenosides [concentrated in the outer layer of root (8% in one analysis), and especially in the 'tail' of the root], many based on 20-S-protopanaxadiol and 20-S-protopanaxatriol. Ginsenosides Rb1 and Rg1 play a large part in eliciting the CNS effects of ginseng, and they also prevent *hyoscine*-induced memory deficits by increasing cholinergic activity. In mice, ginsenoside Rb1 was found to "exert an anticonvulsive effect on *strychnine* poisoning" and "antagonise the shock syndrome produced by *cocaine* intoxication". Ginsenosides also compete with *GABA* receptor ligands as agonists. Four year-old plants were analysed as separate plant parts, for the presence of ginsenosides – leaves [1.078% Rg1, 1.52% Re, 1.11% Rd, 0.74% Rc, 0.55% Rb2, 0.18% Rb1; 5.19% total], leaf stalks [0.33% Rg1, 0.19% Rc, 0.14% Re, 0.11% Rd; 0.76% total], stems [0.4% Rb2, 0.3% Rg1, 0.07% Re; 0.76% total], main root [0.38% Rg1, 0.34% Rb1, 0.19% Rc, 0.15% Re, 0.13% Rb2, 0.09% Rf, 0.04% Rd, 0.02% Rg2; 1.35% total], lateral roots [0.85% Rb1, 0.74% Rc, 0.67% Re, 0.43% Rb2, 0.41% Rg1, 0.2% Rf, 0.14% Rd, 0.09% Rg2; 3.53% total], and root hairs [1.51% Re, 1.35% Rb1, 1.35% Rc, 0.78% Rb2, 0.38% Rd, 0.38% Rg1, 0.25% Rg2, 0.15% Rf; 6.15% total]. In general, root-branches and rhizomes contain saponin levels several times higher than the main root [8.28% and 6.23%, respectively, in one analysis]. The root has also yielded 0.05-0.5% essential oil, peptides, maltol [sedative – see **Passiflora**], small amounts of B-vitamins, folic acid, salicylic acid, vanillic acid, sugars, amino acids and minerals [including zinc, iron, manganese, copper, cobalt and vanadium]. Red ginseng contains mostly ginsenosides Rb1, Rb2, and Rc; this differs from white ginseng [which contains mostly Rb1 and Rg1, as well as lower total saponin levels], in that it contains virtually no malonylginsenosides, as the malonylginsenosides mRb1, mRb2 and mRc convert to Rb1, Rb2 and Rc, respectively, on heating. Maltol is believed to be formed in steamed [red] ginseng through transformation of maltose and an amino acid. The leaf and stem contain similar saponins to those in the root, the leaf in higher yield [up to c.12.2%]; flowers and buds have yielded 15% saponins; seed has yielded 0.7% saponins (Attele et al. 1999; Bruneton 1995; Chuang et al. 1995; Fulder 1993; Hsu et al. 1986; Huang 1993: Kubo et al. 1980).

P. japonicum root has yielded 13.6-20.6% saponins, including ginsenoside Ro, chikusetsa saponin II and chikusetsa saponin IV; P. japonicum var. major root has yielded 9.34% saponins (Huang 1993).

P. notoginseng root has yielded 5.3% ginsenoside Rb1, 3.9% ginsenoside Rg1, and ginsenoside Rd as the major constituents [up to 86% of total saponins]; 13.6-20.6% total saponins have been found. It comes in black or white varieties; the large, black roots are said to be the best quality (Chuang et al. 1995; Huang 1993).

P. quinquefolia root has yielded mostly ginsenosides Re [1.04%], Rb1 [0.26%] and mRb, as well as Rg1 [0.24%], Rd [0.095%] and Rc [0.063%]; total saponin content may range from 1.7-4.9%. Saponin levels are 1.5-5 times higher in wild varieties than in cultivated varieties (Chuang et al. 1995; Huang 1993; Soldati & Sticher 1980). Roots have also yielded 0.069% panaxytriol, 0.019% panaxynol, 0.018% panaxydol and 0.0093% falcarindiol, polyacetylenes which inhibit the production of nitrites by inducible nitric oxide synthase [see also **Siler**] (Wang et al. 2000).

P. zingiberensis root has yielded 12% saponins, mostly arasaponins A, B, C, D, E and R, which produce panaxadiol and panaxatriol on hydrolysis. Root extract shows more potent antiirradiation effects than other Panax spp. A standard dose of this herb is 1-1.5g, 3 times a day (Huang 1993).

Panax ginseng is a perennial plant to 60cm tall with a fleshy, persistent root; stems erect, terete, glabrous, smooth, slender, in cultivation 1 joint added annually; primary root attached immediately below short rhizome, thick, light yellow, with a rounded head, cylindrical or fusiform, often oblique, branched at lower end, 1-2.5(-5)cm diam. Leaves palmately compound, numbers affected by plant age (usually 1 for a 1-yr old, 3-6 for mature plants); leaflets (3-)5, upper 3 larger, almost similar in size and shape, oblong-elliptic or obovate, 4.5-15 x 3-5.5cm, lower 2 smaller, elliptic or ovate, 2-4cm long, apex acuminate, base cuneate, margin

serrate, sparsely ciliate, glabrous; petioles long. Peduncles scapose, terminal, 7-20cm long; inflorescence umbelliform, simple, containing 4-40 flowers; flowers small, 2-3mm diam.; sepals 5, green; petals 5, cream-yellow, ovate, apex obtuse; stamens 5, filaments short; anthers oblong-orbicular. Ovary inferior, 2-locular; styles 2, united at base; pistil 1; disc cup-shaped. Fruit a berry-like drupe, compressed-spherical, 5-9mm diam., many crowded forming heads, bright red at maturity; seeds 2, hemispherical, cream-white, 5-6 x 4-5mm. Fl. Jun.-Jul. (after 3rd or 4th year), fr. Jul.-Sep. (Hu 1976).

In mixed forest in humus-rich soil with broad-leaved and coniferous trees, in high mountains of n.e. China, Manchuria [Kirin Mts.] and Korea.

Wild ginseng is best gathered from Aug.-Sep., when fruits are red or leaves are yellowing; very old plants are more valued. The root is very carefully dug out, with soil being scraped aside with a bone-needle. Optimum climate for Kirin ginseng has temp. ranging from -10 to 10°C, annual rainfall 50-100cm. Cultivated ginseng is often grown in fields under shading frames, providing c.80% shade. This artificial shading is often accompanied by an increased need for the use of pesticides and fungicides, but usually gives a viable harvest from 3-4 years, with higher yields. Growing in forest conditions simulating the natural habitat, incorporating natural shading, gives a slower-growing crop taking 5-12 years to reach a harvestable state, but the herb is of higher quality. Also requires wind protection. Soil should be well-drained, of a light-medium texture; regular weeding is appreciated. Prefers 20-30mm water per week; soil should be kept damp, but not soaked; water in the evening. The roots will rot if the soil is too wet. Propagation from seed is in autumn, planting 30-60cm apart, up to 15cm deep; seed may lie dormant for at least 18 months after planting, and should be fairly freshly gathered. Germination is aided by keeping seed in moist sand at 8°C for 3 weeks prior to planting in the ground. Plants die back every autumn, returning in spring. The cultivated root is harvested in the same time period as wild roots, from [4-]6-7[-16] year-old plants, after dismantling the shading frame. Roots are generally cleaned of dirt, washed, and the finer rootlets removed, before they are processed; rootlets may be processed separately (Hu 1976; Huang 1993; Kimmens 1975; Whitten 1999).

PANCRATIUM

(Amaryllidaceae)

Pancratium maritimum *L.* – sea daffodil
Pancratium trianthum *Herb.* – kwashi, spider lily
Pancratium spp.

The genus name Pancratium translates roughly as 'all-powerful'. It has been suggested that Pancratium spp. [as 'chreston'] were used in the mystery rites of the early Christians. P. maritimum is believed to be the identity of the 'narkissos' flowers often featured in ancient Minoan art in sacred and sometimes seemingly shamanic contexts. By extension, it might also represent the narkissos picked by Persephone at the time of her abduction by Hades [see also **Narcissus**] (Webster et al. 2001). P. trianthum is used by Bushmen of Dobe, Botswana as a ritual entheogen. Often planted around shrines and other areas of sacred importance, the cut bulb of the plant is rubbed on an incision made on the forehead. The effects are felt more or less immediately, and are said to consist of vivid, colourful visions (De Smet 1996; Emboden 1979a; Schultes & Hofmann 1980).

P. arabicum has yielded lycorine, lycorenine, homolycorine, tazettine, haemanthidine [pancratine], *galanthamine* and sickenbergine (Ahmed et al. 1964).

P. biflorum has yielded lycorine, pseudolycorine, tazettine, pretazettine, *phenethylamine*, *tyramine* and *hordenine* (Lundstrom 1989; Martin 1987).

P. maritimum has yielded lycorine, lycorenine, homolycorine, demethylhomolycorine, haemanthidine, tazettine, *galanthamine*, sickenbergine, vittatine, *hordenine*, *tyramine*, N-methyltyramine, *phenethylamine* and 44 other alkaloids [0.2-0.42% alkaloids in bulb, 0.22-0.4% in rhizome, 0.12-0.3% in stem, 0.28-0.37% in seed, 1.1% in seed capsule] (Ahmed et al. 1964; Lundstrom 1989; Sandberg & Michel 1963).

P. sickenbergeri has yielded lycorine, homolycorine, tazettine, haemanthidine, sickenbergine and *galanthamine*.

P. tortuosum has yielded lycorine, tazettine, haemanthidine, *galanthamine*, vittatine and sickenbergine (Ahmed et al. 1964).

P. trianthum aerial parts yielded 0.39-0.42% alkaloids, and underground parts yielded 0.49-0.52% alkaloids, consisting of *galanthamine*, hippeastrine, tazettine, haemanthidine, lycorine, trispheridine, trianthine and *hordenine* (Dabire & Muravjova 1983; Martin 1987).

Pancratium spp. are known to be very toxic, and caution is advised. See also **Narcissus**.

Pancratium trianthum is a small, bulbous scapose herb with a basal rosette of strap-shaped leaves, linear, mostly appearing with the flowers. Flowers solitary, sometimes several together in scapes, bisexual, regular, white or greenish-white, in an umbel at the apex of an erect, solid leafless stem, subtended by 2 or more membranaceous bracts; perianth funnel-shaped, with a long tube and 6 narrow, spreading segments; stamens 6, united with a conspicuous coronal cup above their insertion at mouth of tube, filaments webbed with a corona. Ovary inferior or superior of 3 carpels with axile placentation; ovules many in each cell. Fruit a capsule; seeds few to numerous, black, often angular or winged.

In dry bushland; tropical w. Africa (Agnew 1974; Schultes & Hofmann 1980).

PANDANUS

(Pandanaceae)

Pandanus anataresensis *St. John* – kiinduur, agen, deair, kiiyen
Pandanus brosimos *Merr. et Perry* – bokuur, kuuriya, kosuuk
Pandanus julianettii *Martelli* – minaar, bidiip, daakhru, guubon, kaawaon, muaar, fuurok, arok
Pandanus odoratissima *L.* **(P. fascicularis** *Lam.***; P. tectorius** *Soland.***)** – jambuka, shivadvishta, indukalika, viphala, kazi, ketuki, keura, fara
Pandanus papuanus *Solms*
Pandanus utilis *Bory* **(P. candelabrum** *Hook.***; P. distichus** *Hort.***; P. elegantissimus** *Hort.***; P. flabelliformis** *E. Carr.***; P. maritimus** *Hort.***; P. mauritianus** *Hort.***; P. odoratissimus** *Jacq., non L.***; P. sativus** *Thou.***; P. spiralis** *Oudem., non R. Br.***; P. spurius** *Miq.***)** – vacoa
Pandanus spp. – screw pines

In Papua New Guinea, the Nangamp of the Wahgi region, and natives of the neighbouring Chimbu region, eat the nuts from some Pandanus spp. to induce a psychotropic state known as 'karuke madness'. In these cases, P. papuanus is believed to possibly be one of the species used. The Wopkaimin near the Ok Tedi region are also known to partake, with whole villages periodically going into 'hysterical excitement'. The condition, sometimes also called 'kapipi', occurs during the Pandanus fruiting season [Sep.-Jan., though P. anataresensis fruits all year]. About 1 hour after eating large quantities of the nuts, some small percentage of the people become restless, excited, and sometimes dangerous to themselves or others. Some people under the influence have been reported as falling from rope bridges and drowning, due to the degree of the intoxication. The eyes are said to become glazed and the user experiences ecstatic visions. As the drug wears off, the user falls into a dazed state, with froth at the mouth and disturbed equilibrium, and a good-humoured mood with 'unwarranted' laughing leads them into a deep sleep. The whole experience is said to last up to 12hrs. The tree responsible is said to probably be a mountain species of Pandanus, all of which grow near Ok Tedi. It may be that more than one species is used. The Wopkaimin have a highly elaborate classification system for their many Pandanus spp. Their men plant and maintain their own specimens of P. julianettii and other species, even marking their trees to keep others away. Pandanus spp. have many other uses – the nuts are usually eaten raw or roasted as food, or pressed for their edible oil. Some are used for their wood in building huts, and torches are sometimes made from the prop-roots. P. anataresensis is used in magic medicine bundles to combat fever, headache, diarrhoea and laboured breathing. As a symbol of semen, its leaf fibres [along with those of P. adino-

botrys, symbolising male blood] are woven with clay into the hair of initiates to make a ceremonial head-dress for male initiation (Bock unpubl.; Hyndman 1984; Reay 1960; Stopp 1964).

The Bimin-Kuskusmin of West Sepik, PNG, use P. anataresensis, P. brosimos and P. julianettii nuts in the 12 stages of their initiation rites, each with a different name for each stage. The nuts are consumed along with other psychoactive plants [and others of unknown pharmacology], in conjunction with a major plant [see *Endnotes*, **Nicotiana**, **Boletus**, **Kaempferia** and **Psilocybe** for more discussion]. Pandanus nuts are associated with female bird-spirit messengers. Nuts of P. anataresensis and P. julianettii are sometimes eaten in ritual circumstances by women, mixed with **Ipomoea** batatas ['sweet potato'] flowers and **Boletus** mushrooms. These nuts are also sacramentally placed under ritual types of cultivated tobacco [see **Nicotiana**], in order to attract nurturing spirits to the latter plant (Poole 1987). Some tribes in PNG will plant a Pandanus tree to magically strengthen a sick person in their village (Paijmans ed. 1976).

Pandanus spp. are important to many aboriginal groups in northern Australia. The leaves are much used as fibre material for making baskets and many other items. The nuts [after dropping to the ground], the fleshy bases of ripe fruit, and soft inner new leaves are eaten as food. The seeds inside the fruits may be eaten raw or roasted. The base of the leaf of P. spiralis is chewed and swallowed to treat sore throat or mouth pain; it has antiseptic, counter-irritant and anodyne activity. The Ngarinyman recognise two varieties of P. spiralis – one which grows along creek lines, and one which grows on sandy flats. The prop-roots of the former variety are decocted and used to treat scabies. A strained decoction of the leaf bases of the latter variety is used as eye-drops, to relieve sore or tired eyes. At Roper River, the nuts are crushed and left in water to ferment, producing a presumably intoxicating alcoholic drink. The Lardil, of Mornington Island in the Gulf of Carpenteria, have a strict ownership of individual Pandanus trees, which they mark with knotted leaves – ignoring this sign may result in retaliation by sorcery (Aboriginal Communities 1988; Isaacs 1987; Smith et al. 1993).

In Tanganyika and Zanzibar, Africa, the aromatic inflorescence of a Pandanus sp. is used to drive out evil spirits from the insane (Watt & Breyer-Brandwijk 1962). In India, Pandanus spp., especially P. odoratissima, are revered for the sensual scent of their flowers. Buddhist cave paintings of Pandanus spp. [probably representing P. odoratissima] in India date back to 5AD (Payak 1998). P. odoratissima is used in Ayurvedic medicine – the leaves are considered aphrodisiac and tonic, treating brain and heart disorders, leucoderma, fever, pain, small pox, scabies, syphilis and leprosy. The oil of the plant is stimulant, antispasmodic and diaphoretic, and is said to "cool and strengthen the brain". The anthers and bract-tips may also be snuffed to treat epilepsy (Kirtikar & Basu 1980; Nadkarni 1976). In Seychelles, aerial roots of P. utilis are decocted to prepare an aphrodisiac beverage (Rätsch 1990).

One researcher bioassayed a sample of roasted Pandanus sp. nuts said to lead to 'karuke madness', eating up to ½ a pound [roughly 230g], which he stated to be more than 10 times the suggested dose. He experienced no effects other than nausea and gastric disturbance, which led him to conclude that the 'karuke madness' was psychosomatic and consisted of some kind of socially-conditioned hysteria (Stopp 1964). This should be considered a premature assumption, though not one to be ruled out entirely. It seems more likely to me that a) the nuts may be quite variable in chemical content, and b) any intoxication might require an even larger amount of said nuts than Stopp had eaten. If Stopp [and my translation of his article] was accurate in reporting the suggested dose, this would mean a mere 23g or so of roasted nuts – which seems to be far from the 'large quantities' usually reported to be eaten for psychotropic effects. It may be [as has been proposed with **Boletus** and the accompanying 'mushroom madness'] that other plants are consumed with the nuts to result in the desired effects, through some chemical interaction similar to that seen with ayahuasca [see **Banisteriopsis**, *Methods of Ingestion*].

Unidentified Pandanus sp. nuts from Minj, New Guinea, were shown to contain small amounts of *DMT*, as well as other unidentified alkaloids (Hyndman 1984).

P. amaryllifolius leaves yielded traces of pyrrolidine lactone alkaloids – pandamarilactonines A & B, and norpandamarilactonines A & B (Takayama et al. 2001).

P. odoratissima nut cores tested tentatively positive for the presence of *DMT*, *harmine* and another β-carboline; these compounds were not detected in the fibrous outer layer of the nut (Heffter 1996; Trout ed. 1997d). Ripe fruit also contains an essential oil [0.02% w/w] consisting mainly of geranyl acetate [27.5%], 3-methyl-3-buten-1-yl-cinnamate [17.1%] and 3-methyl-3-buten-1-yl-acetate [10.1%], with traces of *eugenol* [0.1%] and α-humulene [0.1%]; as well as sterols, fatty acids and amino acids (Vahirua-Lechat et al. 1996).

P. utilis [from Madagascar] nuts have been shown to contain *DMT* as the major component, as well as other indole compounds that were tentatively identified as *N-methyltryptamine* and *harmine*; in another assay, only *harmine* was tentatively observed (Heffter 1996; Trout ed. 1997d).

Nuts of edible Pandanus spp. can be quite nutritious, being high in protein, carbohydrates, fibre and fats (Hyndman 1984).

Pandanus odoratissima is a dioecious shrubby tree to 6m tall, rarely erect; stems much branched, stems and branches winged with distinct leaf scars; aerial roots present, usually in the form of prop roots, supporting the stems. Leaves glaucous-green, 0.9-1.5m long, in 4 rows, spiralled, crowded towards apices of stems or branches, simple, linear, ensiform, caudate-acuminate, coriaceous, bases sheathing, margins recurved, margins and midrib prickly, marginal spines pointing forward or backward. Inflorescences dense, pedunculate spikes with large spathe-like bracts; flowers very reduced, unisexual; perianth usually absent. Male spadix with numerous subsessile cylindric spikes 5-10 x 2.5-3.8cm, formed by stamen filaments fused into a column, enclosed in long white fragrant caudate-acuminate spathes; staminal column 6-13mm long; anthers longer than slender filaments, cuspidate, inserted along whole length of upper portion. Female spadix solitary, 5cm diam., spikes pedunculate; with 1-locular, superior ovary sometimes confluent with adjacent ovaries to form a cylindroid mass of obpyramidal groups of 6-10 or fewer; stigmas separate or united, short, reniform, yellow; ovules solitary to many, basal or parietal; carpels united into hard, smooth phalanges, aggregated on a thick rachis forming a syncarp when mature. Fruit an oblong or globose syncarpium 15-25cm long and wide, yellow or red; individual fruit a drupe, numerous (50-60), usually woody, bright red, orange or yellow when ripe, often 2- or 3-toned, each consisting of 5-12 carpels; carpels 5-7.5cm long, turbinate, angular, the crown smooth, convex, +- depressed round the reniform stigmas; seed solitary.

Sea coast of the Indian Peninsula on both sides, Andamans (Harden ed. 1990-1993 [for some genus detail]; Kirtikar & Basu 1980).

Pandanus utilis is a tree to 20m tall, branched. Leaves 50-75cm x c.8cm, firm, erect, glaucous, with red spines. Male inflorescence simply branched, spathe broad, shortly subtended, spike 10-20cm long; stamens in long, slender umbellate columns; anthers linear, filaments of equal length. Stigmas sessile, reniform, flat, 2-2.5mm wide. Fruit a solitary syncarp, 15cm diam., trigonous-globulose, pendulous, long-pedunculate; drupes c.100 in syncarp, 3-8-locular, 3-3.5cm long, 2-3cm wide, free from middle, upper part convex, pyramid-shaped, lower part mostly prismatic, scarcely narrowed, base truncate, apex not areolate but truncate and +- sulcate; endocarp arranged below middle of drupe, mesocarp fibrose-medullary.

Madagascar, cultivated in Mauritius, Bourbon, West Indies and C. America, as well as a household ornamental plant for indoors and greenhouses (Engler 1900).

P. utilis should be grown in a sunny position; prefers 18-29°C temp., 25% or more relative humidity. Propagate from seed or offsets. Let surface of soil dry out between waterings. Bring inside for winter months, in non-tropical areas. Commonly suffers from mealybug infestations of leaf nodes and axils (pers. comms.).

PAPAVER

(Papaveraceae)

Papaver albiflorum *(Bess.) Paczoski*
Papaver armeniacum *(L.) DC.* **(P. roopianum** *(Bordz.) Sosn.***; Argemone armeniaca** *L.***)**
Papaver bracteatum *Lindl.* **(P. orientale var. bracteatum** *Ledeb.***)** – oriental poppy, great scarlet poppy
Papaver cylindricum *Cullen*
Papaver decaisnei *Hochst. et Steud.*
Papaver fugax *Poir.* **(P. caucasicum** *M. Bieb.***)**
Papaver oreophilum *Rupr.*
Papaver orientale *L.* **(P. intermedium** *DC.***)** – oriental poppy
Papaver pavoninum *Schrenk*
Papaver rhoeas *L.* **(P. orientale var. intermedium** *(DC.) Grossh.***; P. strigosum** *(Boenn.) Schur***)** – field poppy, common poppy, red poppy, lal-poshta, rakta-posta, hexe, amapola, amapola de China
Papaver setigerum *DC.* **(P. somniferum ssp. setigerum** *(DC.) Corbiere***)** – wild opium poppy, wild setaceous poppy, small-flowered opium poppy
Papaver somniferum *L.* – opium poppy, white poppy, carnation poppy, amapola, amapola de opio, sclafmohn, khas khas, abiphena ['serpent's foam'], aphim, ophim, ying-su-qiao [seed pods in TCM]
Papaver tauricola *Boiss.*
Papaver triniaefolium *Boiss.*
Papaver spp. – poppies

Poppies are well known to all as popular ornamentals, but the best known is P. somniferum, source of medicinal and narcotic alkaloids [concentrated in 'opium', the dried and sometimes processed latex from the seed pods], as well as the commercial poppy seeds used in cooking. This species, now considered a cultigen, was originally derived from P. setigerum, probably in the n. and w. Mediterranean region. It has a long and rich history of use for purposes of analgesia and intoxication, properties which have been known for millennia. The medicinal use of poppy capsules was mentioned in the Egyptian Ebers Papyrus [c.1550BC].

The Egyptians regarded it as a sacred plant for priests, warriors and magicians. The Assyrians, Greeks, Romans, and later the Arabs and Indians, all grew and used the herb, and depicted it in their artwork and artefacts of religious significance. Extracts of the mature plant were often mixed with wine and other herbs for consumption [see *Methods of Ingestion*; note that combining opiate alkaloids with alcohol can be a risky and potentially deadly affair]. Persian coffee-houses [see **Coffea**] once sold a poppy decoction called 'kokemaar', which was drunk as hot as possible and produced a 'violent' intoxication. The Greeks usually chopped the poppy heads and infused them in water or wine, the mixture being called 'mekoneios' ['flavoured with opium']; opium itself was called 'mekoneion'. Many cultures across Eurasia held it sacred, and respected its powerful pharmacological actions. This certainly aided in the rapid spread of its cultivation. One of its current strongholds is the Golden Triangle region of s.e. Asia, which supplies much of the world with opium for the production of heroin [diacetyl-*morphine*, a semi-synthetic drug]. The indigenous peoples who are induced to grow it for sale cannot rightly be blamed, though, due to their forceful exploitation. Many of them smoke opium traditionally, and many are chronic users [or addicts]. Shamans of the Miao in the Triangle smoke it before and during their trance rituals. In India, P. somniferum enjoys the usual array of medicinal and narcotic uses, but the seeds, mixed 2:1 with wild lettuce seeds [see **Lactuca**], are mixed with water, and the extracted mucilage mixed with sugar and taken for insomnia. Hakims used it as an aphrodisiac "believed to lengthen the time of seminal discharge during coitus, but the drug after a temporary stimulation diminishes sexual desire and causes impotence" (Anderson 1993; Emboden 1979a; Kapoor 1995; Nadkarni 1976; Pendell 1995; Rätsch 1992; Von Bibra 1855). In Nepal, Kirati shamans sometimes use opium for shamanic travel, and believe it to be "directly connected to the Seti Naga, one of the eight sacred snakes of the underworld" [see **Naja and Ophiophagus**]. It is also used medicinally to treat all kinds of poisoning, and is an offering to Shiva (Müller-Ebeling et al. 2002).

In Germany, P. rhoeas has been known as 'hexe', denoting an association with witches (De Vries 1991). In 1735, an Irish herbalist [k'Eogh] recorded that P. rhoeas is "cooling and refreshing...By drinking a decoction of five or six heads in wine, pain is alleviated and sleep is induced... the bruised leaves of the green heads can be applied to boils, hot ulcers, and burning fevers" (Chevallier 1996). P. rhoeas has been used medicinally as a sedative, soporific, antitussive and emollient (Chiej 1984), and in India the capsule latex is considered to be a narcotic and mild sedative (Nadkarni 1976).

Although the Chinese have been cultivating P. somniferum since at least 1057AD, it was generally for ornamental and food purposes [ie. seeds]. They imported opium from India since at least the 13th century for medicinal use. By the 19th century, opium smoking had been introduced to China, who tried to outlaw its importation by the British, leading to the Opium Wars [which still occur today, with some different players...] (Emboden 1979a; Kapoor 1995). The politics of poppy cultivation, opiates and the heroin trade [and heroin use] are very complex for the naïve, and are beyond the scope and intentions of this book. It should be said that the detailed discussion of opium and its use here should not in any way be taken to be an endorsement of heroin.

Morphine content of P. somniferum latex does not reach its peak until 15-21 days after the petals have fallen from the seed-pods [capsules], and does not fall significantly after that, even in dried pods. At this point the rays on top of the pod will probably be beginning to curve upwards, and the colour of the pod starts to become whitish and glaucous. This is the best time to 'lance' the pods for opium collection. Lancing should be done with a fine, sharp blade, preferably taped or guarded so that only about a 1mm edge emerges. If the walls of the pod are pierced completely, the latex bleeds inside the pod and is essentially lost for this purpose. The blade should pierce the outer skin, though, which allows the latex to bleed externally. Cutting methods tested to be most efficient for yield were either a single vertical incision, or the 'Turkish spiral cut', beginning at the top and spiralling around the pod to the bottom in one long incision. With the vertical methods, subsequent lancing can be made a few days later – however, longer cuts initially reduce the *morphine* content of the subsequent lancings. The first lancing is apparently the only one to contain *papaverine*, and is preferred. Lancing is preferably done in the evening, and the latex is scraped from the pods when it has congealed and turned a dark brown colour, preferably before 8am the next morning. However, in India, lancing is done after midday, so that the hot sun quickly dries a skin on the latex and it is less likely to be lost [alkaloids are also highest between midday and 4pm], although low in *morphine* content at this time – see below. This congealed latex is opium. Opium may be smoked or decocted as is, or it may be prepared for smoking in a form known as 'chandu' (Kapoor 1995; Pendell 1995; pers. obs.).

One way to make chandu is to dissolve the raw opium in boiling water, which is then filtered and concentrated. The concentrate is gently roasted until it becomes brittle – it is then extracted first with cold water, then again with warm water. The extracts are combined and concentrated until reaching c.25% moisture content, and then packed into sealed earthenware jars to age before being ready for smoking. During this stage, it may be attacked by **Aspergillus** fungi which could potentially add to the strength and toxicity of the chandu (Bock & Voogelbreinder in press; Pendell 1995).

A crude opium extract can be prepared simply by boiling finely chopped mature poppy heads in water, then filtering and concentrating the extract. However, it has a greater content of moisture and plant 'gunk' [chlorophyll, sugars etc.] that render it less efficient for smoking purposes. Opium is often simply mixed with **Nicotiana** or **Cannabis** and smoked in a pipe [usually a water pipe], but it is most efficiently utilised with vapourisation, usually requiring a specialised glass pipe or similar improvised device [see *Methods of Ingestion*]. The charred black residue left in the pipe after a smoking session is called 'dross', and is sometimes scraped out and re-smoked – it contains less *morphine*, but more of the secondary alkaloids that are more stupefying in effect. The leaves and dried pods can also be smoked, for a milder effect. Opium and poppy parts can be decocted in water and drunk, though care must be taken with dosage. With good opium, for oral consumption, a lump around the size of a small pea should suffice, but practice may be needed to find an optimum dose. Opium can also simply be swallowed. Tender leaves and petals are tasty and fairly harmless eaten in salads (Pendell 1995; pers. obs.).

'Laudanum' ['tinctura thebaica'] is a tincture of opium, though the term originally referred to a solid extract. The first fluid preparations of laudanum used canary wine as the solvent, and in addition to opium, contained saffron [see **Crocus**] and other herbs (Kapoor 1995). The laudanum known in modern medicine is made using opium dissolved in 70% alcohol, adjusted to contain c.1% [w/v] anhydrous *morphine*; it is used in doses of 0.3-2ml (Martindale 1952).

Opium and the opium poppy [P. somniferum] are narcotic, sedative, hypnotic, analgesic, euphoriant, sudorific, antispasmodic, antitussive and cause constipation [thus relieving diarrhoea]. Higher doses cause nausea, vomiting, weak and rapid pulse, constricted pupils, thirst, cold skin and eventual sleep or coma – death may occur through respiratory and circulatory depression. A lethal dose may be as low as 300mg of opium in some individuals, although tolerances differ between people, and addicts can tolerate higher doses. Continual use usually causes both physical and psychological addiction (Chevallier 1996; Chiej 1984; Morton 1977; pers. obs.). Seeds of P. somniferum have shown some anticancer properties (Aruna & Sivaramakrishnan 1992).

P. albiflorum has yielded *thebaine*, *protopine*, allocryptopine, berberine [AChEI], corytuberine and other alkaloids (Onda & Takahashi 1988; Preininger 1986; Ulrichová et al. 1983).

P. armeniacum has yielded *thebaine*, *protopine*, armepavine, coptisine [AChEI], cryptopine, palmatine, sanguinarine [AChEI] and other alkaloids (Preininger 1986; Ulrichová et al. 1983).

P. bracteatum contains [w/w] up to 2.73-4.57% *thebaine* in its capsules; content increases with plant age [highest (1.7% dry) c.8wks after beginning flowering, 6wks after petals drop]. Roots [collected early in flowering period] have also yielded 0.7-1.3% *thebaine*. Iranian strains [where the plant is native] yield only 2 alkaloids, mostly *thebaine*, as well as alpinigenine; Turkish pods yielded 0.3% *thebaine* and 0.225% salutaridine. Other alkaloids found include isothebaine, *codeine*, orientalidine, oripavine, neopine, *nuciferine*, *protopine*, coptisine, oxysanguinarine and alpinine. This ornamental is a prohibited plant (Aynehchi & Jaffarian 1973; Corrigan & Martyn 1981; Nyman & Bruhn 1979).

P. cylindricum has yielded *narcotine*, *thebaine*, armepavine, *papaverine* and other alkaloids (Preininger 1986).

P. decaisnei is the only poppy other than P. setigerum and P. somniferum shown to yield *morphine*, and it also contains *codeine*, *narcotine*, *papaverine*, *protopine* and *thebaine* (Preininger 1986).

P. fugax has yielded *narcotine*, *nuciferine*, *protopine*, *thebaine*, armepavine, aporheine, chelerythrine [AChEI], coptisine, palmatine, sanguinarine and others (Preininger 1986; Ulrichová et al. 1983).

P. orientale may contain [w/w] 0.001-3.08% *thebaine* in its capsules, and 0.01-0.95% in stems, with lesser amounts in the leaves. 'Goliath' cultivars are generally more potent (Aynehchi & Jaffarian 1973; Corrigan & Martyn 1981). Different chemotypes have been found – of 5 types from Iran analysed, A yielded [from dry seedless capsules] 1-1.25% oripavine; B yielded 0.8-0.88% oripavine and 0.1-0.4% *thebaine*; C yielded 0.5% oripavine and 0.3% isothebaine; D yielded 0.5% oripavine and 0.3% alpinigenine; and E yielded 0.8-1.2% oripavine, 0.3-0.35% *thebaine* and 0.05% alpinigenine (Shafiee et al. 1977). The plant inhibits human plasma AChE (Orgell 1963b). This ornamental is a prohibited plant in some places. A nursery in Victoria [Australia] was recently raided by police for possessing the plant for sale – they had been unaware of its illegality, being a popular cottage ornamental (Arnold 1996).

P. oreophilum has yielded *nuciferine*, *protopine*, *thebaine*, sanguinarine, allocryptopine, berberine, magnoflorine [see **Magnolia**] and other alkaloids (Preininger 1986).

P. pavoninum has yielded 2-methyl-1,2,3,4-tetrahydro-β-carboline, from the whole plant (Shulgin & Shulgin 1997), as well as allocryptopine, coptisine, papaverrubines D & E, *protopine*, rhoeadine and sanguinarine (Preininger 1986).

P. rhoeas has yielded *protopine*, *thebaine*, allocryptopine, berberine,

coptisine, sanguinarine and other alkaloids (Onda & Takahashi 1988; Preininger 1986); root has yielded 6-MeO-2-methyl-1,2,3,4-tetrahydro-β-carboline [2-methyl-*pinoline*]. P. rhoeas var. chelidonioides has yielded 2-methyl-1,2,3,4-tetrahydro-β-carboline (Shulgin & Shulgin 1997). Flower petals from P. rhoeas contained anthocyanins, but no alkaloids; a 10% ethanol extract [given i.p.] showed sedative effects in mice (Soulimani et al. 2001). In tissue culture, callus tissue from the plant was shown to contain *morphine*, *thebaine* and *narcotine* (Khanna & Sharma 1978).

P. setigerum contains a similar group of alkaloids to P. somniferum, including *morphine*, but yields lower quantities of a less-potent sap (Preininger 1986). Capsules have yielded 0.11% *morphine*; 0.045% in leaf; 0.05% in stem; and 0.03% in root (Kleinschmidt 1958). A prohibited plant, sometimes growing as an escaped weed.

P. somniferum, like other poppies, contains a wide array of alkaloids, mostly of the isoquinoline class. The chief component in mature plants, concentrated in the latex, is *morphine*, followed by *codeine* and *papaverine*, and also containing *thebaine*, allocryptopine [anaesthetic], berberine [respiratory stimulant, sedative, hypotensive, AChEI], coptisine [antimicrobial, AChEI], corytuberine [respiratory stimulant, retards pulse, increases reflex excitability in frogs], cryptopine [skeletal relaxant, respiratory stimulant, hypotensive – similar to *papaverine* and berberine], gnoscopine, isoboldine, isocorypalmine, laudanidine, laudanine [similar activity to *strychnine*], laudanosine [causes agitation, incoordination, convulsions], magnoflorine, narceine [stimulates respiration, antitussive, hypotensive], *narcotine*, *protopine*, reticuline, sanguinarine [adrenolytic, local anaesthetic, AChEI], somniferine and other alkaloids, as well as nor-, pseudo-, oxy- and other derivatives of some of the above. It also contains meconic acid, glucose and fructose (Brochmann-Hanssen & Nielsen 1966; Kapoor 1995; Preininger 1975; Preininger 1986; Rastogi & Mehrotra ed. 1990-1993; Ulrichová et al. 1983). The 'Norman' strain developed by Australian scientists, as well as other recently developed strains, contain predominantly *thebaine* and oripavine, which are extracted and used as precursors for medicinal opioid drugs (Fist et al. 2000). The 'Norman' strain now comprises a large portion of Tasmanian poppy crops. This is presumably partly due to the frequent 'poaching' of poppy heads from the peripheries of plantations, by locals and visitors to this island state (pers. comms.). Oripavine and *thebaine* are much more toxic and less psychoactive than *morphine* or *codeine*, though as far as I am aware, there have not yet been any reports of accidental toxicity from human ingestion of crude extracts from such strains.

In P. somniferum, terminal capsules contain the most *morphine*; *morphine* content rises rapidly at first, then levels off as the capsule approaches maturity [about 40 days after flowering], yielding up to 7.5% *morphine*, up to 1.5% *codeine*, up to 2.4% *papaverine*, up to 0.95% *thebaine* and up to 2.7% *narcotine* – though the values are usually much lower (Bernáth et al. 1988; Tookey et al. 1976). Alkaloid levels also may fluctuate widely over the period of 1 day. In general, *morphine* levels are highest at early morning [pre-sunrise], late morning, and evening, being lowest at midday and afternoon, as well as night. *Thebaine* levels tended to increase towards midday, as did *codeine* levels, but patterns of variation were wide (Fairbairn & Wassel 1964). It is usually stated that the seeds do not contain opium alkaloids, but many strains have been shown to contain traces of *morphine*, *codeine* and other alkaloids. Indian P. somniferum seeds [off-white in colour] yielded 0.0175% *morphine*, 0.0043% *codeine*, 0.0041% *thebaine*, 0.0067% *papaverine* and 0.023% *narcotine*; slate-blue seeds from the Netherlands yielded only 0.004% *morphine*, 0.00019% *codeine*, 0.0001% *thebaine*, 0.000017% *papaverine* and 0.000084% *narcotine*. I know many people who have successfully decocted a 'poppy wash' from the seeds and consumed it, although dosage is harder to predict, and unpleasant side-effects are often more predominant (Paul et al. 1996; Pendell 1995; pers. obs.). There is a strong possibility that the alkaloid content measured in seeds derives from traces of opium clinging to the seed-surface. P. somniferum is a prohibited plant in most countries, though its cultivation is rarely interfered with except if plants show signs of lancing for latex.

Opium from P. somniferum may contain 3-38.4% *morphine*, 0-8.8% *papaverine*, 0.2-8% *codeine*, 0.75-11.9% *narcotine* and 0-3.2% *thebaine* (Anderson 1993; Bernáth et al. 1988; James 1950; Von Bibra 1855).

P. tauricola has yielded *narcotine*, *nuciferine*, *protopine*, *thebaine*, armepavine, cryptopine, palmatine and other alkaloids.

P. triniaefolium has yielded *nuciferine*, *papaverine*, *protopine*, *thebaine*, armepavine, coptisine, palmatine, sanguinarine and other alkaloids (Preininger 1986).

Papaver somniferum is a bluish-green erect annual herb to 1m or more high, with milky sap or latex in all parts; root a shallow branching taproot, with many branching laterals; stems robust, smooth, hollow, with scattered stiff hairs. Leaves alternate, obovate-lanceolate, 5-18cm long, margins sharply but unevenly toothed and wavy, with bristle-pointed lobes; tapers to a stalk-like base; forms a dense rosette when young; stem leaves sessile, ovate, 3-10cm long, shallowly lobed, base heart-shaped, clasping the stem. Inflorescence often much branched, with long erect stiffly bristled stalks; flowers solitary, 4-5cm diameter; sepals 2(-3), cupped, shed as the flower opens; petals 4, rounded, overlapping, delicate, coloured either white, or pale lilac to pink with a darker spot at the base; stamens many. Fruit a globose capsule, glabrous to glaucous, dull or bluish-green, straw-coloured when dry, 2-5cm diameter, with 7-10 or more persistent ray-like ridges at apex; ripe fruit opens by pores beneath the ridges. Seeds usually dark brown to black, numerous, minute, covered with a fine network of veins, kidney-shaped on close inspection.

Almost worldwide in warm temperate zones, cultivated or as an escaped weed. P. setigerum also occurs as a weed, and is distinguished by its smaller stature, and smaller, much more slender capsules.

Seeds germinate in late autumn or early winter; stems appear in early spring; flowers late spring to summer, continuing until plants die in autumn [if moisture is still applied] (Chiej 1984; Parsons & Cuthbertson 1992; pers. obs.). Sow seeds where they are to grow, and keep soil moist. Seedlings emerge in around 10 days and are delicate, and the opium poppy does not transplant well. They enjoy moderate to full sun, and a well-drained manured or composted soil. Preferred soil pH is 7. Phosphorous is important in early growth, and nitrogen later, improving the quality and yield of latex. Boron is also necessary, and sodium in small concentrations may increase *morphine* levels. Plants should be thinned out, selecting the most vigorous to remain, when still small. Poppies are cold-resistant, but sensitive to frosts, and do not tolerate heavy rain and strong, drying winds (Kapoor 1995; Morton 1977; Pendell 1995). Tropical conditions with high light levels and heat have been shown to increase alkaloid production in P. somniferum (Bernáth et al. 1998).

PARMELIA

(Parmeliaceae)

Parmelia conspersa *(Ehrh.) Ach.* **(P. subconspersa** *Nyl.***; Lichen conspersus** *Ehrh.***; Xanthoparmelia conspersa** *(Ehrh. ex Ach.) Hale***)** – jevud hiosig, earth flower, peppered rock shield

Parmelia karatschadalis – silavalka, charela, phathar-ke-phul, davala, hinna-i-korisha, stone flower, rockmoss, yellow lichen [all names for this and the three species directly below]

Parmelia paraguariensis *Lynge* – duftfletche ['fragrant lichen']

Parmelia parietina *L.* – common wall lichen

Parmelia perforata *(Jacq.) Ach.* **(Parmotrema perforatum** *(Jacq.) A. Massal.***; Parmotrema reticulatum** *(Taylor) M. Choisy***)** – perforated ruffle lichen

Parmelia perlata *(Huds.) Ach.* **(P. trichotera** *Hue***; Lichen chinensis** *Hale et Ahti***; Parmotrema chinense** *(Osbeck) Hale et Ahti***; Parmotrema perlatum** *(Huds.) Choisy***)** – powdered ruffle lichen, shaileyam, shilapushpa, ushna

Parmelia sulcata *Taylor* – waxpaper lichen, net-marked Parmelia, powdered shield lichen, hammered shield lichen

Parmelia spp. – lichens

P. conspersa [and possibly other unidentified lichens] is considered potently magical and sacred by the Pima and Papago of s. Arizona and n.w. Mexico. It is believed to confer luck in matters ranging from hunting to love. In one of their legends, a cannibal monster is overpowered by cigarettes made from this lichen. Mixed with tobacco [see **Nicotiana**] and smoked in cigarettes, it reputedly "makes young men crazy" and dizzy. Its 'narcotic' effect has been described as similar to that of **Cannabis** (Lipp 1995; Sharnoff undated, citing Curtin 1984). The lichen may also be used to make a yellow dye (Smith 1921). Other unidentified lichens used by the Mojave and Kiowa are reported to have similar properties (Kumar & Upreti 2001). In the New Mexico region, an unidentified grey lichen is boiled "and given to one who talks and laughs to himself", or for headaches (Sharnoff undated, citing Curtin 1974). In Mauritania, P. paraguariensis is imported from the north and smoked by men, crushed with tobacco [1 part lichen to 10 parts tobacco]. It is also burned as an insect repellent. Although normally odourless, it is soaked in fragrant substances including rose oil, and used by women as a powdered perfume (Lange 1957).

P. molliuscula sometimes causes poisoning in sheep and cattle who eat it when other food sources are scarce, resulting in paralysis, and sometimes death (Turner & Szczawinski 1991). In the Canadian Rocky Mountains, bighorns have been observed feeding habitually on a yellowish-green rock-dwelling lichen, the identity of which was not divulged. It was also said that "local Indians...found the lichen to be a narcotic." Of the sheep, it was also said "small ewes have been observed repeatedly leaving the group to scrape this lichen off the rocks with their teeth. The habit becomes so tenacious that the animals wear down their teeth to the level of the gums" (Siegel 1989).

Parmelia spp., such as P. cirrhata, are eaten as a vegetable in times of famine in Sikkim, India. Three species of Parmelia are used to prepare a crude drug known as 'chharila' in India. This is used in Ayurvedic and Unani medicine as an aphrodisiac, analgesic and carminative, which may also be used to treat sore throat, dyspepsia, diseases of blood and heart, stomach disorders, bronchitis, scabies, leprosy, excessive salivation, and other disorders. Powdered, it is applied to wounds or snuffed as a cephalic; its smoke relieves headaches (Saklani & Upreti 1992). The Indian P.

karatschadalis, P. parietina, P. perforata and P. perlata are also considered soporific and sedative, and may be used as incense to relieve headache (Nadkarni 1976). P. sulcata has reportedly been used in Indian folk medicine to treat "cerebral maladies" (Kumar & Upreti 2001). During the Middle Ages in Spain, P. sulcata was used to treat disorders of the brain. According to the Doctrine of Signatures, it would be effective due to its wrinkled brain-like appearance (Gonzalez-Tajero et al. 1995).

Many Parmelia spp. and other lichens are toxic to humans when eaten raw, due to their indigestibility and chemical content. Symptoms from eating small amounts may simply consist of stomach cramps and discomfort. Some lichens can cause contact dermatitis, known as 'woodcutter's eczema' (Turner & Szczawinski 1991). See also Usnea spp. in *Endnotes*.

P. cirrhata has yielded salazinic acid, protolichesterinic acid and atranorin (Saklani & Upreti 1992).

P. comtseliadalis and P. linctina contain brominated fatty acids (Rezanka & Dembitsky 1999).

P. conspersa has yielded salazinic acid (Smith 1921), usnic acid, stictic acid and norstictic acid (Brodo et al. 2001).

P. furfuracea yielded 0.63% methyl-β-orcinolcarboxylate, 0.87% atranorin and 1.13% 5-chloroatranorin (Caccamese et al. 1985).

Parmelia conspersa is a lichen – lichens are a dual symbiotic organism consisting of one or more fungi and one or more algae species. Lichens are usually identified primarily by the fungal half of the relationship. In this case, the host alga is a Protococcus sp. Thallus closely adnate, middle-sized or larger, straw-coloured, covered +- thickly with minute black dots, varying in overall colour towards greenish or yellowish, smooth or somewhat wrinkled, often sorediate or bearing coralloid branchlets toward the centre, the lobes long and rather narrow, crowded and often imbricate, sometimes much-branched, margins wavy to crenate, imbricated central lobes often forming a continuous crust; black below with brown margins, dark rhizoids usually present; apothecia subsessile, small to middle-sized, 3-12mm across, the disc concave, chestnut-brown, exciple subentire to crenulate; hypothecium hyaline to brownish; hymenium hyaline or brownish above; paraphyses rarely branched; asci clavate to broadly clavate; spores (2-)8(-many), hyaline, ellipsoid, 8-12 x 4.5-7µ, non-septate.

On sunny side of rocks and rarely on wood, sometimes on tiles; throughout northern US, southward in the mountains (Fink 1935). The psychoactive Pima 'earth flower' was reported as being ash-grey in colour, though other medicinal Pima earth flowers have been reported with different colours (Sharnoff undated, citing Curtin 1984), suggesting that this name is not exclusive to only one kind of lichen.

PASSIFLORA

(Passifloraceae)

Passiflora actinea *Hook.* **(P. paulensis** *Killip***)**

Passiflora alata *Dryand.* **(P. brasiliana** *Desf.***; P. maliformis** *Vell***; P. mauritiana** *Du Pet.***; P. oviformis** *Roem.***; P. sarcosepala** *Barb.***)** – winged stem passionflower, maracuja de refresco, granadilla

Passiflora alba *Link et Otto* **(P. adenophylla** *Mast.***; P. atomaria** *Planch. ex Mast.***; P. stipulata** *Aubl.***; P. subpeltata** *Ortega***)** – wild passionfruit, white passionfruit, white passion vine, granadilla, granada de zorra

Passiflora biflora *Lam.* **(P. brighamii** *S. Watson***; P. lunata var. costata** *Mast.***; P. transversa** *Mast.***; Decaloba biflora** *(Lam.) M. Roem.***)** – two-flowered passionflower, ala de murcielago, camacarlata, guateguate, parche

Passiflora bryonioides *Kunth* **(P. bryonifolia** *Kunth ex Spreng.***; P. inamoena** *A. Gray***)** – cocapitos, granadina, pasionaria del monte

Passiflora caerulea *L.* **(P. hartwiesiana** *Hort. ex Mast.***; P. mayana** *Veitch ex Voigt.***)** – blue passionflower, blue passionfruit, hardy passionflower, burucuya, murucuja, viricuja

Passiflora capsularis *L.* **(P. hassleriana** *Chod.***; P. paraguayensis** *Chod.***; P. piligera** *Gardner***; P. pubescens** *Kunth***)** – capsule-fruited passionflower, calzoncillo, maracuja branco miudo

Passiflora coccinea *Aubl.* **(P. fulgens** *Wallis ex E. Morr.***; P. toxicaria** *Barb. Rodr.***; P. velutina** *DC.***)** – red granadilla, granadilla agria, granadilla venenosa, costada sacha, snekie marcoesa, thome assu, marudioura, monkey guzzle

Passiflora costaricensis *Killip*

Passiflora x decaisneana *M.J.E. Planch.* **(P. alata x quadrangularis;** often misidentified as **P. quadrangularis)**

Passiflora edulis *Sims* **(P. middletoniana** *Paxt.***; P. pallidiflora** *Bertol.***; P. pomifera** *M. Roem.***; P. rigidula** *Jacq.***; P. rubricaulis** *Jacq.***; P. vernicosa** *Barb. Rodr.***; P. verrucifera** *Lindl.***)** – passionfruit, edible passionflower, purple grenadilla, purple-shelled passionfruit, granadilla, rosa del passione, maracuyá, maracuja, maracuja de doce, maracuja peroba, parcha amarilla, parche, couzou, lilikoi, linmangkon

Passiflora eichleriana *Mast.*

Passiflora foetida *L.* **(P. balansae** *Chodat***; P. hastata** *Bertol.***; P. hibiscifolia** *Lam.***; P. hispida** *DC.***)** – stinking passionflower, running pop, popping jay, wild watermelon, love in the mist, fit weed, granadilla, flor de granadita, bedoca, bombillo, bejuco canastilla, amapola, maracuja de cobra, maracuja de lagartinho, parchita de culebra, puropuro, ñorbo cimmarón, kin-val, kpà-zu, kpà-toto, ogwu agwo

Passiflora incarnata *L.* **(P. edulis var. kerii** *Mast.***; P. kerii** *Spreng.***)** – wild passionflower, old field apricot, apricot vine, serpent's tongue, pop apple, may pop, may apple, maricock, maracock, mahcawq, fiore della passione, ground ivy, holy trinity flower

Passiflora involucrata *(Masters) A. Gentry* **(P. quadriglandulosa var. involucrata** *(Masters) Killip***; P. vitifolia var. involucrata** *Masters***)** – chontay huasca

Passiflora jorullensis *HBK* **(P. medusaea** *Lem.***; P. trisetosa** *DC.***; Cieca trisetosa** *(DC.) Roem.***)** – coanenepilli

Passiflora ligularis *Jussieu* **(P. serratistipulata** *DC.***)** – granadilla, granadilla de China, pomme d'or

Passiflora mollissima *(HBK) Bailey* **(P. tomentosa** *Triana et Planchon***; Tacsomia mollissima** *Kunth.***)** – banana passionfruit, banana poka, granadilla cimarrona, curuba, tumbo, tintin, trompos

Passiflora murucuja *L.* **(Murucuja ocellata** *Pers.***; M. orbiculata** *Pers.***)** – Dutchman's laudanum, bullhoof

Passiflora oerstedii *Mast.* **(P. dispar** *Killip***; P. populifolia** *Triana et Planch.***; P. praeacuta** *Mast.***; P. purpusii** *Killip***; P. rojasii** *Hassl. ex Harms***)** – granadilla

Passiflora quadrangularis *L.* **(P. macrocarpa** *Masters***; P. tetragona** *M. Roem.***)** – giant grenadilla, granadilla, granadilla real, maracuja mamao, sandia de la passion, barbadine, badea, grote markoesa, mereekoeja fireberoe, quijon, tumbo

Passiflora quitensis *(Benth.) Killip*

Passiflora rubra *L.* **(P. bilobata** *Vell. non Juss.***; P. cisnana** *Harms***; P. obscura** *Lindl.***)** – Dutchman's laudanum, bullhoof, bat wing, liane couleuvre, pomme de liana zombi, pasionaria de cerca

Passiflora suberosa *L.* **(P. angustifolia** *Swartz***; P. puberula** *Hook. fil.***)** – cork-barked passionflower, pap bush, noxbe cimarron, huero de gallo, pintero

Passiflora warmingii *Mast.*

Passiflora spp. have fruits with a juicy, edible pulp, and are widely cultivated. P. incarnata and its close relatives, including P. edulis [common edible passionfruit], have long been used as sedatives and antidepressants. P. incarnata received its common name 'passionflower' because to the Christian mind, the flower is evocative of the holy trinity, Christ's crown of thorns etc., and was used by Jesuit teachers to represent the passion of Christ. Today, P. incarnata sees widespread use in over-the-counter herbal preparations, for insomnia and anxiety. In Europe, a tincture of the herb is used as an antispasmodic for patients with Parkinson's Disease. The Cherokee use a tea of P. incarnata root as a 'social drink', and to wean babies; they also use it as a liver tonic, and external wash for wounds and earaches. Other Native American groups use the herb to treat swellings and sore eyes, and also use the root as a tonic (Bremness 1994; Hamel & Chiltoskey 1975; Vanderplank 1996). In the tropical Americas, a 'mildly inebriating wine' is made from the fruits (Festi & Samorini 1999a). In Pernambuco, Brazil, huge quantities of P. incarnata fruit juice or the leaf are taken mixed with 'jurema' [see **Mimosa**] (Da Mota 1997; Ott pers. comm.). In common with P. edulis, P. incarnata has fruit with delicious

edible pulp and juice, though the yield of juice per fruit is lower in P. incarnata. Archaeological finds suggest that Native Americans in the region of the south-eastern US have used P. incarnata fruit as food for thousands of years. This species is now sometimes used in breeding with P. edulis and others [which are from subtropical and tropical zones, as opposed to the temperate native climate of P. incarnata] to give greater cold-hardiness to cultivated passionfruit vines (McGuire 1999).

The roots of the rare P. involucrata are used as a psychotrope and ayahuasca additive [see **Banisteriopsis**] by the Yahua of Peru (Montgomery pers. comm.). In Colombia, the Kubeo give the fruit juice to children for sore throats, and a leaf decoction for insomnia (Schultes & Raffauf 1990). In the West Indies, P. murucuja or a similar species known as 'Dutchman's laudanum' is considered an "excellent substitute for opium" [see **Papaver**]. The concentrated sap is often the part used; otherwise, the flowers are made into a water infusion, or powdered and added to wine or other alcoholic spirits, in which form they are "regarded as a safe and effective narcotic" (Cooke 1860). P. rubra is also known as 'Dutchman's laudanum' in the West Indies, and is similarly used as a narcotic. In Ecuador, the fruits are known to be narcotic, and they are added to chicha [see *Methods of Ingestion*]. Also in Ecuador, leaves of P. ligularis and P. mollissima are used as a narcotic, sedative, antispasmodic, anthelmintic and diaphoretic. In Peru, the liquefied fruit of P. quadrangularis is taken as a sedative, and in Brazil, the fruit rind is used for the same purpose. The roots, leaves and flowers have abortifacient properties, and the stems are considered toxic. In Indo-China, the fresh root is known to be a strong narcotic and poison. In Brazil, P. alata is used to treat anxiety and insomnia. It has edible fruit. Similarly, P. caerulea is used as a sedative and antispasmodic in Italy, and as a sedative, anthelmintic, emmenagogue and diuretic in Argentina (Duke & Vasquez 1994; Festi & Samorini 1999a; Pammel 1911; Perry & Metzger 1980; Vanderplank 1996). In Brazil, P. caerulea is used as an emetic (Pammel 1911). P. coccinea is used in the Amazon in decoction, taken 3 times a day, to treat fever. Its fruit and flowers are edible (Duke & Vasquez 1994), and the herbage is psychoactive [see below].

The Aztecs used P. jorullensis as an analgesic, diuretic, diaphoretic, and treatment for poisoning or snakebite (Emboden 1979a). In Mexico, the petals of P. foetida [known as 'amapola' – Spanish for 'poppy'] are consumed in tea as an opium substitute [see **Papaver**] (Rätsch 1998), and P. edulis twigs are infused as a sedative (Nicholson & Arzeni 1993). P. edulis is reportedly used as a psychotrope by indigenous Paraguayans, possibly with **Pereskiopsis** scandens (Stuart 2002b). In Malawi, the leaves of P. edulis are used to treat insomnia, epilepsy and migraine (Festi & Samorini 1999a). In Brazil, P. edulis leaf is used as a sedative tea, and the fruit juice is drunk as a cardiac tonic (Duke & Vasquez 1994); P. foetida is also used there as an antispasmodic (Pammel 1911). In Nigeria, an infusion of P. foetida fruit and leaves [2-3 tablespoons] is taken for its sedative and hypnotic effects to treat hysteria (Nwosu 1999). In India, leaves of P. foetida are applied to the head to treat dizziness and headache (Nadkarni 1976). As P. hispida, this species has also been reported in use as a 'narcotic' in Jamaica (Pammel 1911).

P. incarnata, when smoked, produces a very mild '**Cannabis**-like' high (pers. obs.; Siegel 1976). The herb may be concentrated to provide a crude extract of alkaloids and flavonoids for use in ayahuasca brews. A dose of 300g dry herb, decocted, has proven sufficient to inhibit MAO for ayahuasca-analogues, in some human bioassays. In another interesting experiment, an extraction was performed on a 1 litre commercial extract of P. incarnata, yielding only c.30mg of crystalline material, as freebase. When vapourised and inhaled, this material sent the subject into a "yellow and purple dot matrix" for several minutes. The nature of the effects was described as very pleasant and 'friendly', but still comparable to *DMT* in power (E pers. comm.). It would be very interesting to learn what compound/s were responsible for this experience. Also, a dry concentrated extract has been successfully smoked previous to vapourising *DMT*, in order to potentiate the latter [though inefficient due to low alkaloid yield] (Gracie & Zarkov 1985). A tincture of fresh P. rubra flowers acted as a pleasant-tasting potent sedative, reminiscent of limeflowers in effect [see **Tilia**] (theobromus pers. comm.).

These herbs generally may treat insomnia, anxiety, hypertension, nervous spasms, and irritable bowel syndrome. They appear to work by a synergy of the total constituents. Passiflora spp. are well-known for their content of alkaloids [β-carbolines, as well as the sedative alkaloid maracugine from some of the older literature, which was most likely a crude mix of β-carbolines], flavonoids and glycosides [some of which are cyanogenic] (Bremness 1994; Bruneton 1995; Festi & Samorini 1999a; Ulubenen et al. 1981). Interestingly, despite sharing similar chemistry, a methanol extract of P. edulis was inactive as an anxiolytic when compared with P. incarnata (Dhawan et al. 2001a).

Although the dried herbage of species used in herbal medicine is generally regarded as being non-toxic in therapeutic doses, there is one unusual report of an individual who experienced marked toxicity presumably related to consumption of a commercially-available P. incarnata extract. This extract, in tablet form, was standardised to contain 500mg active constituents per tablet. The batch of tablets taken by the patient was examined by chromatography and shown to have a similar profile to other batches of the product, as well as P. incarnata herb. The patient experienced nausea after taking 3 tablets [the recommended therapeutic dose]; the next day she took 4 tablets, and "began vomiting profusely". By the third day, she was still suffering these symptoms, as well as tachycardia, fatigue and drowsiness. One week later, she had fully recovered (Fisher et al. 2000). Based on this report, it should be advised that caution be taken with Passiflora spp. [and any substance!], as some people have unusual sensitivity, or allergy, to certain compounds. The starting dose in any experimentation should always be small to begin with, for this reason.

Extended feeding on Passiflora spp. [such as P. alba, P. aurantia, P. herbertiana, P. suberosa] has been implicated in stock poisonings, producing a CNS syndrome involving excitation, convulsions, staggering, incoordination, sometimes drowsiness, ataxia, diarrhoea or constipation, and occasionally death. Although these plants are known to be cyanogenic, other principles are also believed to be involved in the toxic syndrome (Everist 1974; Hungerford 1990; Hurst 1942; McBarron 1983). Also, P. adenopoda has caused fatality, and is cyanogenic, containing linamarin and lotaustralin; the pericarp of the unripe fruit has caused poisoning in humans, and produces HCN, though completely ripe fruit did not produce any HCN. In cyanogenic species, cyanogens are usually most concentrated in the leaves, stems, and arils of immature seeds. Unripe fruits are often considered toxic. It is worth bearing in mind that in a survey of over 570 Passiflora spp., 2/3 were found to be cyanogenic. Others not listed elsewhere here include P. amabilis, P. antioquiensis, P. apetala, P. aurantia var. pubescens, P. biflora, P. brachystephana, P. cinnabarina, P. conzattiana, P. coriacea, P. cuprea, P. filamentosa, P. laurifolia, P. lindeniana, P. lobbii, P. lutea, P. manicata, P. nitida, P. pendens, P. perfoliata, P. pittieri, P. platyloba, P. racemosa, P. sanguinolenta, P. sclerophylla, P. talamancensis, P. trifasciata, P. vespertilio and P. vitifolia (Saenz & Nassar 1973; Seigler et al. 1982; Shaw et al. comp. 1959; Spencer 1988). See *Chemistry of Psychoactive Compounds* for a discussion on the properties of cyanogenic glycosides and glucosides.

P. actinea leaves yielded 0.005% *harman* and 0.119% maracugine (Neu 1954b).

P. alata leaf has yielded 0.0217% β-carbolines [as *harman*], and 4.48% flavonoids [vitexin, isovitexin, isoorientin, 2"-xylosylvitexin] (Oga et al. 1984); earlier examinations found [in leaves] 0.082% *harman*, 0.49% maracugine, and 0.32% passiflortannoid, and [in roots] 0.128% *harman* and 0.152% maracugine (Neu 1954b). The cyanogenic glucosides tetraphyllin B-4-sulphate and epitetraphyllin B-4-sulphate have also been found (Spencer 1988).

P. alato-caerulea, a hybrid between P. alata and P. caerulea, contained the same cyanogens as P. caerulea (Seigler et al. 1982). The highest levels of HCN were produced in the root, with lesser [but still significant] amounts in all other parts of the flowering and fruiting plant [with unripe fruit]; lowest amounts were produced in the ripe pericarp and ripe aril, and none was found in the ripe seed (Spencer 1988).

P. alba has yielded 0.0075% alkaloids including *harman* [0.000039%] (Löhdefink & Kating 1974; Neu 1956), as well as cyanogenic glycosides (Fischer et al. 1982; Hurst 1942). The fresh plant [100g] has been successfully used in an ayahuasca analogue to inhibit MAO; however, strong side-effects continued for 3 days. Symptoms included headaches and general uneasiness; any attempt to place sugar or meat in the mouth [even in tiny amounts] caused immediate throat constriction and pain (E pers. comm.).

P. aurantia has been shown to produce hydrocyanic acid in the fruits and stems, but not in leaves (Hurst 1942).

P. biflora has not been analysed for alkaloid content; however, in feeding tests with butterflies and their larvae [see **Heliconius**], *harman*, *norharman* and *harmine* were detected in the insects (Cavin & Bradley 1988), so it would seem likely that these alkaloids are also found in the plant.

P. bryonioides was shown to contain *harman* – 0.00017-0.00027% in leaves and stems, and 0.000017-0.000027% in roots. In chromatography of the extract of stems and leaves, many other bands were visualised but not identified (Neu 1956; Poethke et al. 1970). The cyanogenic glycoside passibryonoidin has also been found in the herb (Spencer 1988).

P. caerulea has yielded 0.0082-0.0378% alkaloids including *harmine*, *harman* [0.000056%] and *harmol*; the flavonoids chrysin [5,7-dihydroxyflavone; MAOI, BZ-agonist, anxiolytic, anticonvulsant], kaempferol [MAOI, potential neuroprotectant] and quercetin; as well as licopine, and 0.006% HCN [in fresh plant] (Festi & Samorini 1999a; Löhdefink & Kating 1974; Medina et al. 1990; Poethke et al. 1970; Sloley et al. 2000; Wolfman et al. 1994). Root, leaf, flower and seed all contained HCN (Watt & Breyer-Brandwijk 1962); in leaf the major cyanogenic glucosides are tetraphyllin B-4-sulphate and epitetraphyllin B-4-sulphate (Seigler et al. 1982).

P. capsularis has yielded *harman* (Neu 1956), and the cyanogenic glycoside passicapsin (Spencer 1988).

P. coccinea leaf [from Adelaide Bot. Gard., Australia] yielded 0.1% passicoccin, a cyanogenic glycoside (Spencer & Seigler 1985); epipassicoccin has also been found (Spencer 1988). It has not been analysed for

alkaloids; however, it is known to be psychoactive. The fresh, leafy stem [c.1.5m length] has been used successfully as an MAOI in ayahuasca analogues [see *Methods of Ingestion*], with pleasant effects of its own, and no reported side-effects. The leaf is also pleasantly psychoactive when smoked (E pers. comm.).

P. costaricensis has not been analysed for alkaloid content, but based on feeding tests probably contains *harman*, *norharman* and *harmine* [see P. biflora above] (Cavin & Bradley 1988).

P. cyanea leaves yielded 0.017% 2"-xylosylvitexin, a c-glycosylflavonoid, as well as 0.005% aesculetin, a coumarin [see **Aesculus**] (Ulubelen et al. 1981).

P. x decaisneana has yielded 0.0022% alkaloids including *harman* [0.000085%] (Löhdefink & Kating 1974).

P. edulis whole plant has yielded c.0.022% alkaloids including *harman* [0.0004% *harman* in fresh leaf and stem]. Leaf has yielded 0.00012% total alkaloids [calculated as *harman*] (Lutomski & Malek 1975b), though in one early examination [cited in Neu 1954b] it is unclear whether no *harman* was found, or its concentration not quantified. Also, 0.000002% alkaloids were found in root, 0.000002% in seed, and 0.000027% in fruit peel. *Harmine* was also found in the fruit peel, seed and root, and *harmaline* in the fruit (Löhdefink & Kating 1974; Lutomski & Malek 1975b; Neu 1954b, 1956; Slaytor & McFarlane 1968). Leaf also has yielded 0.004% [w/w] *tryptamine* and acetyl-*tryptamine* [the latter experimentally verified as being present as an intermediate in biosynthesis of *harman*, although it could not be detected in the plant] (Schneider et al. 1972; Slaytor & McFarlane 1968; Smith 1977b), as well as 0.196% maracugine and 0.42% passiflortannoid (Neu 1954b). Leaves and stems [Japanese greenhouse plants, harv. Mar.] have also yielded cycloartane triterpenes [cyclopassifloic acids A-D, 0.003% combined] and their related saponins [cyclopassiflosides I-VI, 0.12% combined], as well as the cycloartane saponin passiflorin [0.25%; not the same as *harman*] and its aglycon, passifloric acid [0.001%] (Yoshikawa, K. et al. 2000). P. edulis forma flavicarpa ['yellow passionfruit'] also yielded 0.0007% *harman* from leaves, 0.00017% from stems, and none from roots (Lutomski & Malek 1975a), though Festi & Samorini (1999a) gave these figures as 0.7% and 0.17%; this was a simple confusion relating to the annoying tendency of Lutomski & Malek to give their yields as mg%. The tranquillising fruit juice of P. edulis has yielded 0.000012-0.0007% alkaloids [*harman*, *harmine*, *harmol*, *harmaline* and an unidentified alkaloid], which were present in greater levels in P. edulis f. flavicarpa, as well as 0.001-0.00106% flavonoids [vitexin, rutin, quercetin, saponarin, saponaretin, homoorientin], 0.000058-0.00016% carotenoids, vitamin C (Lutomski et al. 1975), and traces of passicol, a polyacetylene compound with antibacterial and antifungal properties (Birner & Nicholls 1973). The leaves have been shown to contain the cyanogenic glycoside prunasin. The fruit juice and peel also contain cyanogenic glycosides, with profiles differing between samples of P. edulis and P. edulis f. flavicarpa. Reports of mandelonitrile rutinoside isomers given here are tentative identifications. P. edulis [as juice/peel] was shown to contain 0.0043%/0.023% prunasin, 0.004%/0.00177% mandelonitrile rutinoside 1, 0.001%/0.0011% mandelonitrile rutinoside 2, 0.0031%/0.00196% amygdalin, and 0.00004%/0.00056% sambunigrin. P. edulis f. flavicarpa was shown to contain 0.0056%/0.0287% prunasin, 0.01%/0.0062% mandelonitrile rutinoside 1, 0.0014%/0.00014% amygdalin, and 0.00032%/0.00157% sambunigrin (Chassagne et al. 1996). The seeds produce HCN (Watt & Breyer-Brandwijk 1962). Fruits contain greatest levels of cyanogens when still unripe (McGuire 1999).

P. eichleriana leaves yielded 0.05% *harman* and 0.5% maracugine (Neu 1954b).

P. foetida has yielded 0.0051% alkaloids including *harman* [0.00007%] (Löhdefink & Kating 1974) and *serotonin* (Festi & Samorini 1999a), as well as cyanogenic glycosides – specimens from Galapagos Is. yielded tetraphyllins A and B, deidaclin and volkenin; specimens from Reunion Is. yielded tetraphyllin B, volkenin and linamarin (Andersen et al. 1998); passifoetidin was found in material of unreported origin (Spencer 1988). The leaf resin from P. foetida var. hispida has yielded traces of 3 polyketides, passifloricins A-C (Echeverri et al. 2001). The unripe fruits contain cyanogenic glycosides, but the ripe fruits have been eaten safely by children (Hurst 1942). The flowers contain a flavonoid pigment, anthocyanin malvidin-3-monoside, and bracts contain anthocyanin delphinidin-3-pentoseglycoside (Shaw et al. comp. 1959).

P. herbertiana stems yielded 0.038% hydrocyanic acid when fresh, 0.015% when dry. Leaves did not contain any, whilst the fruit pulp appeared to be rich in hydrocyanic acid (Hurst 1942). Flowers contain a flavonoid pigment, anthocyanin peonidin-3-pentoseglycoside (Shaw et al. comp. 1959). Leaf and stem from Queensland, Australia [harv. Nov.] tested tentatively positive for alkaloids (Webb 1949).

P. incarnata leaves and stems have yielded 0.00012-0.1% alkaloids, or up to 0.2% crude alkaloids [0.000055-0.011% *harman*, 0.002-0.015% *harmine*, *harmaline*, 0.002-0.021% *harmol*, *harmalol*], c.1.5% flavonoids [including *apigenin*, kaempferol, orientin, isoorientin, saponarin, saponaretin, vitexin, isovitexin], 0.05% maltol [CNS-depressant, sedative, anticonvulsant, likely BZ-agonist] and ethylmaltol, the hydrocarbon derivative nonacosane, a miscellaneous 8-pyrone derivative, phenolic acids, coumarins, phytosterols [such as sitosterol and stigmasterol], 0.1% essential oil, and cyanogenic glycosides (Bruneton 1995; Hultin 1965; Löhdefink & Kating 1974; Lutomski 1960a, 1960b; Lutomski et al. 1968a; Neu 1954a, 1954b, 1956; Oga et al. 1984; Poethke et al. 1970; Schilcher 1969; Soulimani et al. 1997; Wren et al. 1988) such as gynocardin [0.01% w/w] (Festi & Samorini 1999a). In one test, leaves and stems were analysed separately; leaves contained 0.00002% alkaloids, and stems contained 0.000012% alkaloids [both calculated as *harman*] (Lutomski & Malek 1975b). Fruits have yielded *serotonin* and vitamin C; roots have yielded *scopoletin* and umbelliferone (Festi & Samorini 1999a). In a Polish study, alkaloid content was lower in field-grown plants [0.005% *harman* and no detectable *harmine*] than in greenhouse-grown plants [0.012-0.019% *harman* and 0.007% *harmine*; 0.025-0.032% total alkaloids, also including *harmol*, *harmalol* and unidentified alkaloids] (Lutomski & Nowicka 1969; Lutomski et al. 1969). The Polish climate would be unlikely to mimic the native conditions of this species, so it is likely that these differences would not apply in warmer regions. Extracts of the herb, as the alkaloid fraction [shown to contain *harman*, *harmine*, *harmol* and 0.07% of 2 unidentified bases (probably *harmaline* and *harmalol*)] and flavonoid fraction [containing 4 flavonoids, as well as *harmol*], were tested separately on mice. Both exhibited sedative activity (Lutomski & Wrocinski 1961), though the presence of *harmol* in the flavonoid fraction makes it unclear what conclusions may be drawn from this. The fluid extract of the herb as used medicinally [45-52% alcohol] has also been shown to contain *harman*, *harmine* and *harmaline*; *harman* and *harmine* were detected at levels of 10-20mg/100ml (Bennati 1968, 1969, 1972; Bennati & Fedeli 1969). When extracts of separate plant parts were tested for anxiolytic activity in mice, the roots and flowers were found to be practically inactive. The main activity was found in methanol extracts of foliage (Dhawan et al. 2001b).

P. jorullensis is said to have yielded *harmol*, *harmalol*, *harman*, *harmine*, *harmaline* and passicol (Emboden 1979a), but I have found no supporting data in the literature.

P. ligularis leaf has yielded 0.0041% β-carboline alkaloids (Martinod et al. 1981). The fruit juice did not contain any detectable cyanogens, but the peel was shown to contain 0.00012% prunasin and traces of mandelonitrile rutinoside 1 [the identification of this latter cyanogen was tentative] (Chassagne et al. 1996).

P. menispermifolia leaves have yielded aesculetin [see **Aesculus**], as well as 0.006-0.016% each of the c-glycosylflavonoids orientin, vitexin, cirsiliol [6-OH-luteolin 6,7-dimethyl ether] and luteolin 7-β-D-glucoside (Ulubelen et al. 1981).

P. mollissima leaf has yielded 0.00213-0.00264% β-carboline alkaloids (Martinod et al. 1981); the cyanogenic glycosides tetraphyllin B-4-sulphate and epitetraphyllin B-4-sulphate have also been found in the herbage (Spencer 1988). The whole fruit was shown to contain 0.00007% prunasin (Chassagne et al. 1996), and the rind contains passicol (Birner & Nicholls 1973).

P. oerstedii has not been analysed for alkaloid content, but based on butterfly feeding tests, probably contains *harman*, *norharman* and *harmine* [see P. biflora above] (Cavin & Bradley 1988). Leaves yielded β-sitosterol, 3-β-D-glucoside, sugars, the flavonoid 2"-xylosylvitexin [0.023%] (Ulubelen et al. 1981), and the cyanogen gynocardin (Spencer 1988).

P. quadrangularis root has yielded unquantified levels of *harman* (Neu 1954b, 1956), and leaf yielded 0.0001% *serotonin*, 0.00003% *norepinephrine* (Applewhite 1973) and *tryptamine* (Smith 1977b); based on butterfly feeding tests, the leaves probably also contain *harman*, *norharman* and *harmine* [see P. biflora above] (Cavin & Bradley 1988). Leaves have also yielded the cycloartane triterpene glycoside quadranguloside (Orsini et al. 1986); the herbage and seed contain cyanogenic glycosides (Fischer et al. 1982; Watt & Breyer-Brandwijk 1962), including tetraphyllin B-4-sulphate, epitetraphyllin B-4-sulphate and passiquadrangularin (Spencer 1988).

P. quitensis has yielded 0.00252% β-carboline alkaloids (Martinod et al. 1981).

P. suberosa has yielded *harman* (Neu 1956 – mis-spelt as P. ruberosa); cyanogenic glycosides including gynocardin (Seigler et al. 1982), volkenin, epivolkenin, passisuberosin and epipassisuberosin have been found (Spencer 1988), as well as their expected by-product, HCN (Shaw et al. comp. 1959). Leaf of July-harvested material growing in Brisbane [Australia] was weakly alkaloid-positive (Webb 1949).

P. warmingii has yielded 0.0022% alkaloids including *harman* [0.000065%] (Löhdefink & Kating 1974), as well as the cyanogenic glycosides linamarin and linustatin (Spencer 1988).

Passiflora incarnata is a herbaceous or woody vine, climbing by tendrils or trailing, up to 8(-10)m long, glabrous or finely pilose. Leaves alternate, suborbicular in general outline, truncate or rounded to a small cuneate base, deeply 3-lobed, 60-150mm long, mid-nerve puberulent beneath, lobes ovate-lanceolate, constricted at base, acuminate, margins finely serrulate; stipules setaceous, deciduous, 2-3mm long; petioles c.80mm long, pubescent, biglandular at or near summit. Peduncle stout, 10cm long, bearing biglandular-serrulate bracts (4-8 x 2.5-4mm) near summit; flowers solitary from axils, 5-merous, perfect, 4-6(-9)cm wide, perigynous with well developed saucer-shaped to tubular hypanthium; se-

pals 3-5, white, mauve, or lavender inside, green outside with keel and awn 3mm long, lanceolate-oblong, 30mm long, alternating with 3-5 petals (also white or pale lavender; shorter than sepals) and attached with them to the margin of the hypanthium, which also bears a corona (a double or triple fringe); outer corona 1.5-2cm long, purple or pink, inner corona 2-4mm long; stamens 5, monadelphous around gynophore, 1-celled, with 3-5 parietal placentae and numerous ovules; styles 3, elongate, with capitate or clavate stigmas. Fruit an edible yellow (lime green when unripe) berry, 5-6cm long. Fl. Jun.-Aug.

Moist or dry soil in fields, roadsides and thickets, also open woods; Virginia to s. Ohio, s. Illinois and Oklahoma, south to Florida and Texas (Gleason 1952; Vanderplank 1996); introduced in Australasia, Hawaii, S. America, Bermuda, and Europe. Due to its extensive root development [shoots may develop up to 6m away from the parent rootstock], this species has potential for becoming an invasive weed under the right conditions, and should be cultivated with care, if at all (McGuire 1999).

Propagate in early spring. Seeds, particularly older ones, may need a 24-hr soak in warm water prior to planting. Sow seed on surface of light soil or peat moss with bottom heat. The best chances for germination are found by using seed from fresh fruit. With some pulp still attached, they should be soaked in a warm place in the juice of the fresh fruit, before sowing with the whole mixture. Apparently the acidity helps initiate germination. Artificial acid applications, or scarification, reduce viability. Best temp. for germination is a constant 19-24°C. When seeds have germinated, plant 2-6cm deep in sand or loam, and let the seedlings develop. Plant out after 6 months.

Or – propagate from 15cm cuttings of half-ripened growth, rooting in sand. Best chances are with end-shoot cuttings, cut closely below the node of the 2nd mature leaf, from the tip; remove bottom leaves, tendrils and flower stalks. A humidity tent is needed in the first 1-2 weeks. Can also be propagated from rooted basal offshoots, or from 4-8cm long root or rhizome fragments. These fragments must be kept moist until planted, to preserve viability.

Prefers light, rich, well-drained soil, not too rich in nitrogen. Mulching around the base of the plant is advantageous, especially in winter to protect from frosts. Prefers warm climates and full sun, though will still grow well in shade. Hardy, dies back in winter, though may not recover from heavy ground-frosts. There is a better chance of surviving frosts if planted on a southern exposure. Needs provisions for climbing, as the vine does not support itself. Much water may be required to establish the plant, though when mature they should not be over watered. Harvest herbage at end of growing season, when fruit have formed (Festi & Samorini 1999a; McGuire 1999; Vanderplank 1996; Whitten 1999). Whitten claimed the alkaloids are at their highest concentration at this point, though I have not been able to find any documentation to support this. However, this does not mean that he was wrong!

PAULLINIA

(Sapindaceae)

Paullinia cupana *Humb., Bonp. et Kunth* **var. sorbilis** *Ducke* **(P. sorbilis** *Mart.***)** – guarana, Brazilian cocoa, uabano, uaranzeiro
Paullinia yoco *Schultes et Killip* – yoco

Guarana, the ground seed of P. cupana var. sorbilis, has been traditionally used as a stimulant by people of the lower and middle Tapajos in the Amazon. The seeds are collected each October, and are then processed for storage. This involves grinding them and mixing with 'cassava' flour [from Manihot esculenta] and water, forming a brown paste. This paste is shaped into sausages, which are baked slowly over a wood fire until very hard. When required for use, a little is grated off [c.½ tsp.] into a cup of hot or cold water, which may be sweetened (Emboden 1979a; Schultes 1942; Schultes & Raffauf 1990). Guarana is said to have originated through the misfortune of a Maue boy, who spread happiness and goodwill everywhere – a jealous evil spirit transformed into a snake and killed the boy when he ventured out alone one day to gather fruit. He was found lying facing the sky with eyes wide open. A bolt of lightning hit the earth, and the boy's mother announced she had received divine instructions to bury his eyes. The first guarana vine grew from these eyes (Erickson et al. 1984).

Guarana soda has been made industrially in Brazil since 1907, and became the 'national drink' in the 1940's (Lleras 1994). Today, guarana is consumed in huge quantity across the world, available as powdered seed, pills or pharmaceutical preparations, an ingredient of numerous 'smart drinks' and 'energy drinks', or in a variety of foodstuffs as a 'healthy' alternative to pure *caffeine*. Guarana is being pushed to partying youth as a drug by pharmaceutical health supplement companies, with often tactless marketing ploys, encouraging its use for a 'high'. Western demand for the herb has caused native peoples to be encouraged to clear large tracts of virgin rainforest for its cultivation. Thus, people purchasing it should be aware of the environmental implications of its use (pers. obs.).

The bark of P. yoco is used as a stimulant tonic in the western Amazon of Colombia, Ecuador and Peru. Natives of the area recognise many different varieties of 'yoco', which are said to be indistinguishable botanically. Starting from the roots, the liana is cut down in 30-90cm lengths. The sections are stored by the villagers for up to a month, the bark only being rasped when it is required for use. At such times, it is freshly rasped and kneaded in water – this is strained and again kneaded and strained. Roughly 90-100g of bark is used for each serve, drunk from a gourd; 1-2 gourdfuls may be drunk early each morning, which staves off hunger and gives endurance until noon, when the first meal is eaten. In higher doses, yoco is used to treat malaria, and as a vermifuge and purgative (Schultes 1942, 1986, 1987b; Schultes & Raffauf 1990; Uscategui 1959).

The sap and seeds of the Central American P. pinnata [Serjania curassavica] are used to stupefy fish, poison arrows, and as a criminal poison (De Smet 1998; Usher 1974). In Africa, the leaf juice is used as a remedy for mental disease; the root and seeds are the most toxic parts (Watt 1967).

P. cupana var. sorbilis seeds may contain c.2.7-6% *caffeine* [seed coats containing the most], as well as 0.02-0.06% *theobromine*, 0-0.25% *theophylline* (Erickson et al. 1984; Gilbert 1986; Maravalhas 1966; Meuerer-Grimes et al. 1998; Power & Chesnut 1919a; Schultes 1942; Suzuki et al. 1992), saponins and 2-3% tannins [with antioxidant activity]. Small doses of guarana exhibit adaptogenic and performance-enhancing effects in animals, while larger doses do not (Espinola et al. 1997; Schultes 1942; Schultes & Raffauf 1990).

P. pinnata has yielded timboin, which is a nerve-poison, causing first convulsions, then paralysis (Watt 1967); leaves and twigs contain saponins and tannins (De Smet 1998).

P. yoco bark has yielded 2.73% *caffeine*, which is also found in the inflorescence (Schultes 1942).

Despite much effort on behalf of the health-food industry to divert attention from this fact, yes, 'guaranine' is identical to *caffeine*. The reason guarana is not as 'jittery' as a cup of coffee in effect, is because of the important complementary tonic role of the other constituents.

Paullinia cupana var. sorbilis is a climbing or suberect shrubby or bushy plant; branches deeply 4-5-grooved, apex dark brown-pilose, soon glabrate, in the main woody and unbranched. Leaves 5-foliolate-pinnate, 20-40cm long; leaflets 10-20 x 4.5-9cm, upper leaves oblong, lower ovate, apex shortly acuminate, acumen +- obtuse, base terminally acutely subcuneate, sides rotundate, shortly to moderately petiolulate, upper partly scattered subrepand-dentate, teeth subobsolete, coarse, mostly obtuse, coriaceous, obscurely latticed-venose, glabrate below, covered with microscopic glands, subscabrous to touch, scarcely punctate pellucid, with lactiferous utricule, sparsely ramificate below, fibres of sclerenchyma close to upper surface, epidermis not mucus-bearing; petioles 7-15cm long, rachis naked, glabrous; stipule small, ovate-subulate from base. Inflorescence a +- ovoid or ellipsoid panicle with cymose branches, solitary, loosely subvillose-pilose, pistillate flowers in inflorescence c.1/6 of total; cincinni sessile, contracted; bracts and bracteoles small, subulate; flowers unisexual, large, odorous; sepals 4, externally setulose-pilose, interior 3mm long, submembranaceous; petals 4, oblong, c.5mm long, margin villose, upper crest shortly appendiculate, shortly deflexed, with short tuft of hairs; receptacle glandulate, shortly ovate, base pilose; stamens 8, filaments complanate, subulate, clothed with long hairs; anther glabrous, introrse, affixed dorsally above base, emarginate. Ovary trilocular, ellipsoid, stipitate, base and apex angustate, in style long-angustate, glabrous; style subulate or filiform, apex with 3 exserted, excurrent stigmas. Fruit a 3-locular capsule 2-3cm long, stipe 6-8mm long, reddish-orange above, deep yellow below, dark or blackish when dry, ellipsoid, apiculate, externally glabrous, internally subfuscous-tomentose; seeds 1-3, c.12mm long, ovoid, glabrous, testa deep reddish-brown or black, aril red, each weighing 1g or less when dry.

Brazilian and Venezuelan Amazon (Erickson et al. 1984; Fridericus & De Martius 1965-1975). Despite reports stating otherwise, P. cupana is still known to occur in the wild state. On the other hand, P. yoco is only known from the wild, growing in a small area along the Putumayo, in the region joining Colombia and Peru (Lleras 1994).

All open flowers on a given flowering branch will be of the same sex on any given day. Male flowers open early morning, and have shed most of their pollen by midday; female flowers are only receptive for 1 day. Fruits ripen within c.75 days.

Seeds germinated in moist sawdust, appearing in 1-3 months. Seedlings are transplanted into 1-litre plastic containers filled with soil, and kept heavily shaded; a year later, in Jan. or Feb. [height of the rainy season], they are planted out where they are to grow. Soil should be deep, well-drained, rich in organic matter, and of a medium to heavy texture. Annual mean temp. in native range is 28-29°C, though it is often cultivated within an annual mean of 20-22°C; tolerates a minimum of 12°C. Annual precipitation must be greater than1400mm, with rain well distributed throughout the year; annual precipitation in native range is 2200-2500mm (Erickson et al. 1984; Lleras 1994).

PEDICULARIS

(Scrophulariaceae)

Pedicularis attollens *Gray* **(Elephantella attollens** *Heller***)** – little elephant's head
Pedicularis bracteosa *Benth.* – cobra head, fern leaf, bracted lousewort
Pedicularis canadensis *L.* – common lousewort, wood betony
Pedicularis groenlandica *Retz.* **(P. surrecta** *Benth.***)** – elephant's head, pink elephants
Pedicularis racemosa *Dougl. ex Hook.*
Pedicularis spp. – betony, wood betony, lousewort, pseudo-ginseng

Special thanks must first be made to Ghostpipe for aiding in the compilation of this entry; it would probably not have existed without him! Pedicularis is a genus of partially-parasitic herbs, requiring the roots of a host plant to survive. Apparently, they are not host-specific. It has recently come to wider knowledge that the flower buds of many Pedicularis spp., when smoked or eaten, can produce **Cannabis**-like psychotropic effects [when dried, they can even look suspiciously like **Cannabis** buds!]. Some describe the herbs as acting as tranquillisers and muscle-relaxants. Potency and quality of subjective effects may vary widely between individual plants and different species. P. bracteosa is said to be psychoactive, and a strain of P. canadensis sampled by numerous independent researchers, including myself, was found to be very similar to moderately-potent **Cannabis** in effect and duration [when smoked]. P. attollens has been found to be similarly active, but less potent. P. groenlandica is also said to be one of the 'milder' species. Pedicularis spp. have also been used in smoking mixtures, both commercial and home-made. One of those that has been commercially available in such mixtures is P. racemosa. It has been claimed that some native N. Americans may smoke Pedicularis spp. in smoking mixtures. Pedicularis spp. have been used in brewing non-traditional beers [see *Methods of Ingestion*]. The European Stachys officinalis [which has similar properties and is also known as 'betony' or 'wood betony'; see *Endnotes*] has, however, been used traditionally to brew beer. P. canadensis has been used most commonly as a medicine by native N. American tribespeople, as an aphrodisiac, analgesic, cathartic, emetic, cardiotonic, antitussive, abortifacient, antitumour and blood-cleansing herb, amongst other applications (Brounstein 1995; Buhner 1998; Ghostpipe pers. comms.; Hamel & Chiltoskey 1975).

In n.w. China, Pedicularis spp. such as P. artselaeri are known as 'pseudo-ginseng' [see **Panax**]. They are used in folk medicine as a cardiotonic, and to treat collapse, exhaustion, general debility, sweating, spontaneous ejaculation and senility, as well as to "invigorate the circulation of blood and mind" (Gao et al. 1997; Su et al. 1998; Zimin & Zhongjian 1991). In some parts of northern Asia, P. lanata is used as a tea substitute [see **Camellia**] (Von Bibra 1855). In India, P. pectinata is used as an astringent and haemostatic (Nadkarni 1976).

P. canadensis, P. lanceolata, P. palustris, P. sylvatica and P. sudetica are recorded as having been toxic to stock animals (Pammel 1911), though the genus is regarded as particularly safe in humans.

Pedicularis spp. have been theorised to absorb phytochemicals from the host plant (Ghostpipe pers. comm.); however, they are usually found to possess iridoid glucosides, neolignan glycosides and/or phenylpropanoid glycosides as the major constituents, as well as alkaloids (Abdusamatov & Yunusov 1970; Zhongjian et al. 1992).

P. artselaeri [flowering whole plant] has yielded 6 phenylpropanoid glycosides [0.0019% artselaeroside B, 0.023% others], a phenylethanoid glycoside [0.0016% artselaeroside A], 3 iridoids [artselaenins A-C, c.0.0017% combined], and 10 iridoid glycosides [0.0006% 6-O-methylaucubin, 0.015% others] (Su et al. 1998).

P. bracteosa leaves yielded the iridoid glycosides aucubin and mussaenoside; stems, flowers and seed pods together only contained aucubin.

P. crenulata aerial parts yielded the iridoid glycosides euphroside [major component], aucubin and plantarenaloside (Schneider et al. 1996).

P. dolichorrhiza has yielded the alkaloids (R)-boschniakinic acid [(R)-plantagonine] and indicamine (Buckingham et al. ed. 1994).

P. groenlandica stems, flowers and seed pods together yielded the iridoid glycosides aucubin and euphroside (Schneider et al. 1996).

P. lasiophrys has yielded 0.0014% cistanoside D, 0.0017% pedicularioside F, 0.00428% verbascoside, 0.00057% cistanoside C, 0.00057% pedicularioside E and 0.00028% 8-epiloganin (Zhongjian et al. 1992).

P. longiflora has yielded 0.0017% verbascoside, 0.00035% longifloroside, 0.00035% cistanoside D, 0.00023% cistanoside C, 0.00023% loganic acid, 0.00017% mussaenoside, 0.00011% pedicularioside I and 0.00011% geniposidic acid (Jia & Liu 1992); another study found four different longiflorosides – A [0.0006%], B [0.001%], C [0.0004%] and D [in a mixture with dehydrodiconiferyl alcohol-4-O-β-D-glucopyranoside] (Wang & Jia 1997).

P. ludwigi has yielded (R)-boschniakine [(R)-indicaine] and (R)-boschniakinic acid (Buckingham et al. ed. 1994).

P. olgae has yielded N-methyl-*cytisine*, (R)-boschniakine, 0.11% (R)-boschniakinic acid, indicainine, pedicularine, pedicularidine, pediculidine, pediculine and pediculinine. The flowering plant, collected in July in Russia, yielded 0.54-0.65% alkaloids (Abdusamatov & Yunusov 1970, 1971; Abdusamatov et al. 1968, 1970, 1971; Buckingham et al. ed. 1994; Khakimdzhanov et al. 1971; Ubaev et al. 1963).

P. palustris tested positive for the presence of c.0.01-0.03% alkaloids (Hultin & Torssell 1965).

P. procera leaves yielded the iridoid glycosides mussaenoside, 6-deoxycatalpol, shanzhiside methyl ester, 8-epiloganic acid [all major components], aucubin and gardoside; stems, flowers and seed pods together yielded only aucubin and 6-deoxycatalpol.

P. racemosa stems, flowers and seed pods together yielded mostly aucubin, and lesser amounts of euphroside (Schneider et al. 1996).

P. rhinanthoides flowering aerial parts [harv. Jul., Russia] yielded 0.38% alkaloids, of which (R)-boschniakinic acid and d-tecostidine were identified (Abdusamatov & Yunusov 1970).

P. silvatica tested positive for the presence of c.0.01-0.03% alkaloids (Hultin & Torssell 1965).

P. striata yielded the phenylpropanoid glycoside pedicularioside A [0.0017%] and the iridoid glycosides acteoside [0.0022%], isoacteoside [0.0022%], decaffeoylacteoside [0.00022%], echinacoside [0.0026%] and 8-acetylharpagide [0.00152%] (Zimin & Zhongjian 1991); P. striata ssp. arachnoides root yielded 0.004% aucubin, 0.0016% 8-O-acetylharpagide, 0.001% dihydrocatalpolgenin and 0.002% of the sesquiterpenoid eremophila-10,11-diene-7α,13-diol (Gao et al. 1997).

Pedicularis canadensis is a hairy, perennial herb; stems simple, closely clustered, to c.40cm high. Leaves scattered, alternate, the lowest pinnately parted, the others partly pinnatifid, all or nearly all petioled, blade to c.15cm long, 5cm wide. Inflorescence a large-bracted raceme, dense and 3-5cm long in flower, elongated to 20cm in fruit; calyx 7-9mm long, split in front, otherwise almost entire, oblique; corolla yellow or yellowish, to 23mm long, strongly bilabiate, upper lip incurved and hooded, 2-toothed under apex, lower corolla lip usually shorter, erect at base, 2-crested above, 3-lobed, lobes commonly spreading, the lateral ones rounded and larger; stamens 4, didynamous; anthers transverse, enclosed by upper calyx lip, cells pointless; stigma capitate. Capsule lance-oblong, flattened, asymmetrical, twice as long as calyx, glabrous, loculicidal, mostly arcuate and opening mostly on upper side; seeds several, slightly winged. Fl. Mar.-May.

In open forest or edge of forest, on open seepage slopes, prairies, clearings; from Quebec to Manitoba, south to Florida, Mississippi, Louisiana, e. Texas and n. Mexico (Correll & Johnston 1970; Hitchcock et al. 1959). Difficult to establish in cultivation. Sow seed where they are to grow. Prefers moist, well drained, peaty soil, and a host grass, in a part-shaded to sunny position (pers. comms.).

PEGANUM

(Zygophyllaceae)

Peganum harmala *L.* – Syrian rue, African rue, wild rue, harmel, harmal, hurmal, isband, esfand, techepak, peganon, churma, besasa, uzerlik, gamarza, gandhya
Peganum nigellastrum *Bunge* – luo-tuo-hao

The seeds of the weedy shrub P. harmala are best known nowadays for two reasons – they are [or were] the source of the red dye 'Turkish red' used in Turkish and Iranian carpets [and for Turkish fezes (Ott 1993)]; and they are now popular as a component of modern ayahuasca-analogues, due to their exceptionally high content of β-carboline alkaloids. The seeds and the whole plant are more or less narcotic in their own right, and are used medicinally throughout their natural range. To the ancient Egyptians, the plant ['besasa'] was associated with the god Bes, and was thought to protect against evil. It may also have been burnt as an incense offering to Bes, who was the guardian deity of women in labour. Modern Egyptians use the seed oil ['zit-el-harmel'] as an aphrodisiac and protective. During the Iranian spring festival of Nuruz, the seeds are burnt – inhaling the smoke of the burning or smouldering seeds is known to be an effective means of obtaining the inebriating effects of this plant. Shamans of the Hunza burn them to enter trance and communicate with otherworldly beings. The Douvans of Bokhara also burn them and become 'exuberant'. Moroccans inhale the fumes to clear the mind and enter a clairvoyant state, as well as to treat headache and to purify themselves to protect against evil (Emboden 1979a; Jordan 1992; Rätsch 1992). Some modern Iranians living in Australia also use it in the same way, to ward off evil spirits (pers. comm.), and it is burned as an incense against the evil eye in parts of Central Anatolia, Turkey (Ertug 2000). In Israel, traditional healers have used the seeds in steam-baths to treat "nervousness, weariness and exhaustion" (Palevitch et al. 1986). In Egypt, the seeds are taken with the pollen grains of dates [Phoenix dactylifera] to "restore sexual potency" (Islam et al. 1991). Bedouins use the plant as an emmenagogue and abortifacient (Mahmoudian et al. 2002).

In parts of India and Pakistan, the seeds are placed on burning charcoal as a fumigant to magically protect new born infants from poor health, as well as during marriage ceremonies. The smoke of the plant is also known to be disinfectant and to repel mosquitos. Also in India, the seeds, taken orally, are said to increase sexual desire and menstrual flow, as well as acting as a galactagogue. In large doses, the seeds have been prescribed to treat asthma, and to procure abortion. As 'techepak', the seeds are consumed in Ladakh, India. They are roasted, pulverised, and sifted [the resulting preparation being known as 'techepakchiatzen'], before being either eaten, or smoked with tobacco [see **Nicotiana**]. Indian Muslims also use the leaves as an incense, called 'dhup'. Elephants have been observed to become furiously intoxicated after eating P. harmala seeds; elephants in this state of rage are referred to as being 'mast' or 'masth'. The plant and its seeds have even been proposed to represent both the Hindu 'soma', and the Iranian 'haoma' [see also **Amanita**]. Amongst the many other uses of the plant in medicine, P. harmala acts as a narcotic, aphrodisiac, antispasmodic, emetic, emmenagogue, galactagogue, alterative, antiperiodic, anthelmintic, antirheumatic, antidiarrhoeal, abortifacient, antimicrobial, diuretic and antiasthmatic (Chopra et al. 1965; Flattery & Schwartz 1989; Hassan 1967; Nadkarni 1976; Navchoo & Buth 1990; Ott 1993, 1998b; Parsons & Cuthbertson 1992).

In n.w. China, P. nigellastrum has been used to treat inflammation, rheumatism and abscesses. The basic extract of the plant has also shown antitumour activity (Ma et al. 2000).

In recent years, P. harmala seeds have become very popular as a potent MAOI for use in ayahuasca analogues [see *Methods of Ingestion*], where **Banisteriopsis** is not available for this purpose. Roughly 3-4g, or 1 heaped tsp. of ground P. harmala seeds is enough to inhibit MAO sufficiently to activate an oral dose of *DMT* in most people. The seeds are often prepared in a lemon juice/water extraction [3:7] which is consumed either shortly before, or with, the *DMT* preparation. Sometimes the ground seed or a dried extract of the seeds is simply encapsulated and swallowed. In larger amounts, up to 15g or more, the psychoactive effects of the seeds by themselves are more noticeable, usually consisting of a heavy hypnotic feeling, sometimes with closed-eye imagery. People seem to react to these harmala alkaloids rather differently at psychoactive levels, according to various studies mostly using pure *harmine* or *harmaline* – some reporting stimulation, or even mild psychedelic effects. P. harmala seeds also may cause more unpleasant side-effects, such as strong nausea and vomiting, especially in psychoactive doses (Ott 1994; Shulgin & Shulgin 1997; pers. comms.; pers. obs.).

The ground seeds may also be smoked, though they do not burn easily. Fortunately, the major alkaloids are very easy to extract in a relatively pure form [see *Producing Plant Drugs*], allowing more accurate dose measurement, and ease of vapourisation. P. harmala seeds [or extract] can be used [orally or smoked] to potentiate or synergise with the effects of some other substances [eg. **Psilocybe** mushrooms, **Cannabis**, **Trichocereus**] when taken during the early part of the experience, or during the peak (Kent 1995; pers. comms.; pers. obs.). The extract may be smoked previous to smoking *DMT*, in order to extend the available time period for inhaling the *DMT* vapours, and to lengthen the experience (Gracie & Zarkov 1985; pers. comms.). The harmala alkaloids when smoked in this way are active in very small amounts, and impart their own character to the experience they are being applied with, 'smoothing the edges' and giving a greater ability to focus shamanic attention (Trout ed. 1998; pers. obs.). Some people enjoy drinking a decoction of the seeds in doses of 5g and above for the mild 'entheogenic' state they may produce, although most people find them unpleasant at psychoactive doses (Most 1985; pers. comms.). Doses of up to 150g of seeds have been survived by humans, although negative effects at such doses are profound. It is worth noting that animals who eat the plant [which they will usually avoid if there is a choice of other foraging herbs] sometimes suffer abortion and death (Mahmoudian et al. 2002).

The dyes produced from P. harmala seeds take two forms – a yellow dye prepared from simple water infusion, and a red dye obtained after chemical treatment. Although the red pigment is thought to derive primarily from oxidised β-carboline alkaloids (Ott 1993), it seems likely that the anthraquinones found in the seeds could contribute to pigmentation (pers. obs.), as quinones are well known plant pigments (Harborne & Baxter ed. 1993).

P. harmala contains predominantly β-carboline alkaloids [such as *harmaline*] and quinazoline alkaloids [such as vasicine (peganine)], with relative proportions differing across different plant-parts at different times of year [see below]. The quinazolines are thought to act as abortifacients through uterine-stimulant activity (Mahmoudian et al. 2002).

Alkaloids are concentrated in the seed coat of the seeds of P. harmala (Gröger 1959). Ripe whole seeds may yield 2-7% alkaloids [much lower yields were said to be obtained from green fruits – see below for some conflicting data]; roots 1.4-3.2% [3% *harmine* was found in roots in one test; as well as *harmaline*, vasicinone and deoxyvasicinone]; stem and fruits 0.8% [in summer stems contained mostly deoxyvasicinone, as well as 0.06% *harmine* and 0.03% *harmaline*]. Harmala-alkaloid content is highest in winter; the seeds contain more *harmaline* than *harmine* in winter, and this pattern reverses in summer; the roots contain more *harmine* than *harmaline* in winter, and this also reverses in summer. The flowering aerial parts have yielded vasicine [respiratory stimulant, bronchodilator, antihypertensive, uterine stimulant, abortifacient], deoxyvasicine [reputed to show cholinergic activity], vasicinone, deoxyvasicinone and *harmine*. In the vegetative material and fruits [not including seeds], vasicine is usually the major alkaloid. In the seeds, *harmaline* is often the dominant alkaloid [2.01-2.09%; or 1/2-2/3 of total], as well as *harmine* [0.3-1.6%], with trace alkaloids including *harmalol*, *tetrahydroharmol*, *harmol*, *tetrahydroharman*, *harmalan*, isoharmine, *leptaflorine* [tetrahydroharmine], 0.0001% harmidine [may be identical to *harmaline*], harmalicine, 8-glucosidyl-*harmine*, 8-glucosidyl-*leptaflorine*, 8-glucosidyl-*harmaline*, 6-OH-*tryptamine* [only in strains from Dijon], vasicine, vasicinone, 0.0008% deoxyvasicinone and oxopeganine [uterotonic, AChEI's]; flavonoids including quercetin, kaempferol [MAOI (Sloley et al. 2000)] and peganetin; and anthraquinones. Other researchers found the unripe seeds [summer harvest] to yield 4.3% *harmine*, 0.28% *harmaline*, 0.28% vasicine and 0.28% deoxyvasicinone; as opposed to the ripe seeds yielding 0.9% *harmine*, 0.6% *harmaline*, 2.5% vasicine and 0.9% deoxyvasicinone. Seed has also yielded 14.23-15.86% of an oil. Also found in the plant are *harman* [in root], harmalanine, harmalicinine, harmalidine, ketotetrahydronor-*harmine*, pegamine, peganidine, isopeganidine, deoxypeganidine, peganol, dipegine, alkaloid YC2 and 9,14-dihydroxyoctodecanoic acid. Seedlings have yielded, as well as *harmaline*, *harmine* and *harmalol*, the alkaloids *harmol*, ruine [8-OH-glucosylharmine], dihydroruine [8-OH-glucosylharmaline] and 6-OH-*tryptamine*, as well as gentisate 2,5-β-diglucoside (Buckingham et al. ed. 1994; Chatterjee & Ganguly 1968; Fischer 1901; Fischer & Täuber 1885; Gill & Raszeja 1971; Gröger 1959; Henry 1939; Khashimov et al. 1970; Kurachko et al. 1970; Marion 1952a; McKenzie et al. 1975; Nettleship & Slaytor 1971; Ovejero 1948; Rastogi & Mehrotra ed. 1990-1993; Reinhard et al. 1968; Rozenfeld 1931; Shulgin & Shulgin 1997; Trout ed. 1998).

P. nigellastrum aerial parts [harv. Aug.] yielded 0.007% *harmine*, 0.0001% 3-phenylquinoline, 0.00006% 3-(4-hydroxylphenyl)quinoline, 0.00006% 3-(1H-indol-3-yl)quinoline, 0.00006% luotonin C, 0.00002% luotonin D, and the flavonoids dihydrosinapylferulate [0.00008%] and dihydroconiferylferulate [0.0001%] (Ma et al. 2000); *harmaline* was found in the roots (Shulgin & Shulgin 1997).

Peganum harmala is a much branched, glabrous, spreading perennial herb 30-80cm tall, with a woody rootstock; stems glabrous, slender, cylindrical below, angled above, rather stiff, branching frequently. Leaves alternate, multifid, divided several times into narrow +- linear acute segments 2-5cm long, bright green, succulent; bristle-like stipules occur at base of each leaf stalk. Flowers solitary on pedicels to 2cm long, leaf-opposed, 1.27-1.9cm across, white; sepals 4-5, often toothed or divided, 8-20mm long, linear, exceeding the petals; petals elliptic-oblong, obtuse, 12-17mm long, creamy-white; stamens mostly 15, inserted at the base of disc, some antherless; filaments dilated below. Ovary deeply 2-3-lobed; styles basal, twisted, 2-3-keeled above middle, the keels stigmatose. Fruit a globose capsule, deeply lobed, 7-10mm long, 8-12mm diam., dehiscing with 3 valves or indehiscent. Seeds dark brown, angled. Fl. summer-autumn.

In arid regions; native to n. Africa, Mediterranean region, east to Tibet and Russia north of the Caspian Sea; introduced in parts of Australia [Vic (only recorded as a pasture-weed in Katamatite, Mooroopna West and Nathalia areas), SA, NSW] and the US [Texas, New Mexico, Arizona,

Nevada] (Chopra et al. 1965; Harden ed. 1990-1993; Jeans 1999; Parsons & Cuthbertson 1992).

Although P. harmala sometimes thrives as a weed, it can be quite difficult to cultivate successfully. Plant viable seed in spring. Approaches to this that have been reported as successful in producing germination include planting in commercial seed-raising mix; planting in a peat moss/sand mix; and folding in a wet paper towel, sealed inside a zip-lock bag and placed under light [reported to produce germination in 4-7 days]. In the case of the zip-lock bag method, sprouts should be carefully removed and potted quickly after germination. Raise seedlings in filtered sunlight and moderate moisture, letting the surface dry between waterings. Later transfer carefully into pots [regular potting soil is reported to be o.k.; a sandy but fertile soil mixture is said to be best] and introduce them gradually into the sun, watering lightly. Well-drained soil is essential as the roots may rot easily if too moist, particularly when plants are still young. Maintain a partial filter from hot midday sun. A heating pad set at 30°C, placed under pots, is reportedly beneficial to aerial and root growth [in areas cold enough for it to be necessary], as is bottom-watering. Bring indoors in winter in colder areas – they often die back at this time and may be stored in a cool, dark, dry place until spring (DeKorne 1994; Grubber 1973; pers. comms.).

PELECYPHORA

(Cactaceae)

Pelecyphora aselliformis *Ehrenberg* – peyote, peote, peyotillo, peotillo, peyote meco ['shaking' or 'rocking' peyote], hatchet cactus

This cactus is a representative of the group of 'false peyotes' found in Mexico [see **Lophophora**], as evidenced by its common names. Reputed in Mexico to have medicinal properties, P. aselliformis is sold in San Luis Potosi markets to treat fever and rheumatic pain (Bravo 1937; Britton & Rose 1963; Schultes 1937a, 1937b).

P. aselliformis has yielded <0.00002-0.003% [d/w] *mescaline*, traces of N-methylmescaline, 0.0002% [w/w] *DMPEA*, traces of N-methyl-*DMPEA*, 0.000018% [d/w] N,N-dimethyl-3-OH-4,5-dimethoxy-*phenethylamine*, 0.00063[d/w]-0.0007[w/w]% *hordenine*, <0.0001% [w/w] *tyramine*, 0.0002% [w/w] N-methyltyramine, 0.000067% [d/w] anhalidine [6,7-dimethoxy-8-OH-2-methyl-THIQ] and 0.0000094% [d/w] *pellotine* (Agurell et al. 1971; Neal et al. 1972; Siniscalco 1983; Štarha 1994).

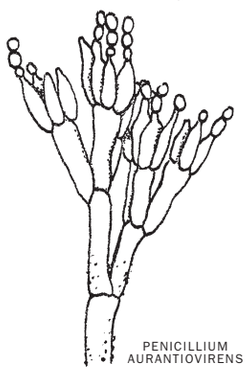
Pelecyphora aselliformis is a tufted, slenderly globose-cylindric, later club-shaped cactus, blue-green to grey-green, 5-10cm high, 2.5-5.5cm diam., covered with tubercles arranged in spirals, solitary or forming clusters; tubercles hatchet-shaped, strongly flattened laterally, somewhat stalked at base, up to 5mm high, axils wooly; areoles at top of tubercles very long and narrow, crowned with an elongated, scale-like grey spine up to 4mm long, with numerous lateral ridges, usually free at apex, giving peculiar pectinate appearance, connivent at base. Flowers central, solitary or several together near apex, funnel-shaped to campanulate-rotate, 2cm long, 3cm wide or more, carmine-violet; perianth segments in 4 rows, the outer sometimes white, oblong, acute; stamens borne at top of tube, much shorter than perianth segments; stigma lobes 4, erect. Fruit a spindly berry deliquescent when ripe; seeds kidney-shaped, brown or blackish, almost smooth.

San Luis Potosi, c. Mexico (Britton & Rose 1963; Haustein 1991).

Slow-growing; requires protection from excessive moisture, and frosts (Trout & Friends 1999).

PENICILLIUM

(Hyphomycetaceae/Trichocomaceae)



PENICILLIUM AURANTIOVIRENS

Penicillium aurantiovirens *Biourge* **(P. verrucosum var. cyclopium** *(Westling) Sams., Stol. et Hadl.***)**
Penicillium chermesinum *Biourge*
Penicillium concavo-rugulosum *Abe*
Penicillium roquefortii *Thom.* – noble mildew, blue cheese mould, king of molds
Penicillium rugulosum *Thom.*

Some Penicillium moulds are best known as being sources of the antibiotic penicillin. However, P. camembertii is used to make 'Camembert' [for the whitish crust], and P. roquefortii to make blue-vein 'Stilton' and 'Roquefort' cheeses [for the blue-veins] (Bock & Voogelbreinder undated; Hobbs 1995). Amongst dream-inducing cheeses [see *Influencing Endogenous Chemistry*], Stilton is one type known to be most effective and to produce the most bizarre dream content (British Cheese Board 2005). Some species and strains of Penicillium can produce ergot-type alkaloids [see **Claviceps**], amongst other diverse compounds.

P. aurantiovirens strain VKM F-229 in culture has yielded *agroclavine*, *elymoclavine*, *penniclavine*, isopenniclavine, *chanoclavine* and aurantioclavine (Solov'eva et al. 1996); a wide array of other metabolites have been found in the species, including penicillic acid, cyclopiazonic acid [both antibiotic, but toxic to mammal liver and kidney], 2,3-dihydroxy-4-phenylquinoline, ergosterol, tremortins A and B [tremorgenic], puberulic acid, poly-(L)-malic acid [proteinase inhibitor] and terrestric acid [a 4-OH-γ-lactone] (Domsch & Gams 1993).

P. chermesinum strain PC 106-I in culture has yielded the little-studied ergot alkaloid costaclavine [see **Claviceps**] (Agurell 1964).

P. concavo-rugulosum in culture has yielded *chanoclavine*, as well as related alkaloids rugulovasine A & B; these latter alkaloids are hypotensive in animals (Abe et al. 1969).

P. roquefortii strain PRL 1463 in culture was found to produce what appeared to be *agroclavine*, *elymoclavine* and *penniclavine* (Taber & Vining 1958); strain IBPM-F-141 and other strains in culture yielded *festuclavine*, isofumigaclavines A and B, and new indoles, roquefortines A [0.00002-0.00036% of commercial Roquefort cheese; antidepressant, local anaesthetic and muscle relaxant in animals; LD50 340mg/kg i.p. in mice], B and C, and 3,12-dihydroroquefortine (Hong & Robbers 1985; Kozlovskii et al. 1979; Ohmomo et al. 1975). Several strains were shown to produce large amounts of (+)-aristolochene in culture, with smaller amounts of valencene. P. roquefortii may also produce PR-toxin (Demyttenaere et al. 2002).

P. rugulosum has yielded *chanoclavine*, rugulovasines A & B, and other indole compounds (Abe et al. 1969).

P. sizovae in culture has yielded *agroclavine*-1 dimer and a mixed dimer of *agroclavine*-1 and epoxyagroclavine-1 (Kozlovskii et al. 1995).

P. dipodomyis and P. nalgiovense have yielded penicillin and dipodazine, a diketopiperazine alkaloid (Sørensen et al. 1999).

Solid fermentation culture of Penicillium sp. WC75209 yielded a new ergoline alkaloid, 1-MeO-*agroclavine*; it inhibits the enzyme LCK tyrosine kinase, which may be beneficial in controlling cancer proliferation, as well as other diseases (Padmanabha et al. 1998).

Some Penicillium spp. also produce benzodiazepines [see *diazepam*] (Rahbaek et al. 1999), such as P. aurantiogriseum [which produces the benzodiazepine auranthine], P. clavigerum, P. commune, P. melanoconidium, P. sclerotigenum and P. verrucosum [which produce sclerotigenin (auranthine B)] (Larsen et al. 2000). P. avellaneum, P. brefeldianum, P. lilacinum and P. thomii have tested positive for alkaloids (Abe et al. 1969).

Penicillium aurantiovirens grows in colonies reaching 4.5-5cm diam. or less in 14 days at 24°C; blue-green, often becoming yellow- or light grey-green with age, in fresh isolates often fading to light ochraceous in centre; reverse uncoloured, yellow, orange or brown. Conidiophores usually finely roughened, in some isolates smooth-walled. Conidia globose to subglobose, 3.5-4µm diam. Odour usually strong, earthy and pungent.

Widely distributed – it has been found in Australia, New Zealand, Europe, e. Siberia, the White Sea, Syria, Egypt, Libya, Kuwait, Pakistan, Somalia, South Africa, Ivory Coast, India, China, Japan and Peru. Usually occurs in forest soils, peat bogs, heathland, grassland, desert soils, sand dunes, caves and on stalactites; it has also been found in water, and growing on many plants, grains, stored fruits, hay, compost, sewerage, fermented food, frozen fruit cake, refrigerated dough products, birds, rabbits and gerbil nests, amongst other things (Domsch & Gams 1993).

PERESKIA

(Cactaceae)

Pereskia corrugata *Cutak* **(Rhodocactus corrugatus** *(Cutak) Backeb.***)**
Pereskia grandiflora *Hort. ex Pfeiffer* – rose cactus, blade apple
Pereskia tampicana *Weber* **(Rhodocactus tampicanus** *(Weber) Backeb.***)**

These plants are interesting leafy cacti, which to the untrained eye do not look like cacti at all! P. aculeata, 'Barbados gooseberry', was suspected of having killed two calves and a horse in Murwillumbah, NSW [Australia]. It was not noted whether this was due to mechanical injury from the spines, or due to chemical poisoning. A human was also reported to have gotten blood poisoning from one of the thorns of this plant (Hurst 1942). In Brazil, crushed stems of a Pereskia sp. ['rose madeira'] are sometimes applied as a poultice to treat cancer (Hartwell 1968).

P. corrugata was shown to contain 0.0005% *mescaline*, *tyramine*, homovanillylamine [3-MeO-*tyramine*] and *DMPEA*.

P. grandiflora was shown to contain β-OH-*mescaline*, 4-MeO-β-OH-*phenethylamine* and *tyramine*.

P. grandifolia was shown to contain *tyramine*, 3-MeO-*tyramine* and 4-MeO-β-OH-*phenethylamine*.

P. tampicana has yielded 0.0013% *mescaline*, *phenethylamine*, *tyramine*, 4-MeO-β-OH-*phenethylamine* and 0.0025% *DMPEA* (Doetsch et al. 1980).

Pereskia tampicana is a leafy shrub; branches often without spines, or spines several, needle-like, black, 2-3cm long, in pairs or in clusters in leaf axils, neither sheathed nor barbed; areoles globular, appearing as knobs along the stem; branches and leaves not easily detached. Leaves alternate, broad, flat, deciduous or somewhat fleshy, c.5cm long, petioled. Flowers solitary, corymbose or paniculate, terminal or axillary, wheel-shaped, 2.5cm long, petioled; axils of sepals without long hair or bristles; petals entire, at least not fimbriate, rose coloured; stamens numerous; style single; stigma-lobes linear. Seeds black, glossy, with a brittle shell, the embryo strongly curved; seedlings without spines.

E. Mexico, known only from the type locality [near Tampico] (Britton & Rose 1963).

It should be noted that there is some confusion regarding P. grandiflora and P. grandifolia [for which reason I have included the illustration of the latter]. P. grandifolia *Haworth* is considered by some to be equivalent to P. grandiflora *Hort. ex Pfeiffer*, though others who have cultivated both species have noted minor differences. It would seem that although they are very similar, more evidence is needed to clarify their classification. P. grandifolia may also sometimes be encountered in the horticultural trade as P. bleo.

Cultivate Pereskia spp. in loose, rich soil, in partial sun. Easily cultivated from cuttings taken in summer; do not let cuttings callus over, but plant immediately. Water moderately, and mist occasionally. Requires heavier feeding than most cacti (Trout & Friends 1999).

PERESKIOPSIS

(Cactaceae)

Pereskiopsis scandens *Britton et Rose*

There does not appear to be any noteworthy useage of this leafy cactus. However, a confusingly-worded passage seems to suggest that "Peireskia sandents (ysypóvori)" is used by indigenous inhabitants of Paraguay, either alone or with **Passiflora** edulis, as a psychotrope. Presumably this should read **Pereskia** scandens (Stuart 2002b, citing E.S. Costantini), but as far as I am aware this name does not exist, so I further presume it refers to the closely related Pereskiopsis scandens.

P. chapistle has been shown to contain *tyramine*, 3-MeO-*tyramine*, *phenethylamine*, and 4-MeO-β-OH-*phenethylamine*.

P. scandens has been shown to contain 0.0022% *mescaline*, as well as *tyramine* and 0.0029% *DMPEA* (Doetsch et al. 1980).

Pereskiopsis scandens is a slender, irregularly branching cactus, climbing or clambering over walls, up to 10m long, with +- rod-shaped shoots; branches terete, greyish, smooth; areoles circular, white-wooly when young, grey in age, with a short spine 5mm long and a bunch of brown glochids in upper edge. Leaves ovate, 1.5-2cm long, flat, glabrous, acute, fleshy. Flowers yellow, from the areoles on old branches, rather large, rotate; pericarpel mostly with leaves or scales. Fruit club-shaped, fleshy, red, maturing slowly (perhaps over 2-3 years), very narrow, 5-7cm long, somewhat tubercled, with a deep umbilicus; seeds few, almost round with narrow collar, white, felted-hairy. Fl. Jun.

S. Mexico (Britton & Rose 1963; Haustein 1991).

Cultivated as for **Pereskia**, but may require more sun (Trout & Friends 1999).

PERIPENTADENIA

(Elaeocarpaceae/Euphorbiaceae)

Peripentadenia mearsii *C.T. White* **(Actephila mearsii** *C.T. White***)** – grey quandong, buff quandong

This Australian tree, recorded earlier last century from numerous locations in Queensland, is now possibly extinct [or at least very rare] due to logging of its natural habitat (Bock pers. comm.). It was found on at least one occasion to yield interesting tropane alkaloids, including *tropacocaine*. Later studies failed to replicate this, but it is known that this species is highly variable in alkaloid content.

Leaves of P. mearsii [from Boonjie, Qld] have yielded 0.25% alkaloids, of which 21% was *tropacocaine*, 11% (+)-3-α-acetoxy-6-β-OH-tropane and 28.4% (+)-2-α-benzoyloxy-3-β-OH-nortropane (Johns et al. 1971). A later study found leafy stems to yield 0.33% alkaloids, consisting of peripentadenine, di-nor-N-peripentadenine, peripentamine and anhydro-peripentamine (CSIRO 1990); the alkaloid mearsine has also been isolated (Buckingham et al. 1994).

Peripentadenia mearsii is a glabrous tree to 19m, bole to 51cm

diam.; outer bark dark brownish, marked by longitudinal lines of lenticels; inner bark pale brown, reddish on outer surface; branchlets drying reddish-brown or olivaceous, slightly angular, older ones greyish, terete, finely rugulose; internodes 1-3(-5)mm diam., 1-9(-30)mm long or much longer at base of some lateral branchlets; stipules deltoid or suborbicular, very caducous. Leaves spiral, rarely subopposite, chartaceous, elliptic- or oblong-lanceolate, (3.5-)5-15(-24) x (1.3-)2-5(-7)cm, apex acuminate, base narrowed and often +- biglandular, margin remotely crenate or crenate-dentate, upper surface shining, lower opaque and paler, midrib slightly elevated above, prominently so below, 5-10(-12) slightly elevated lateral nerves; petiole +- pulvinate at both ends, 0.6-2.5(-4.5)cm long, channelled above, rounded below, +- narrowly winged on margins. Flowers solitary, axillary, subtending leaves often reduced and soon falling, in bud 5-ribbed from outcurved margins of sepals, at anthesis pendulous, back from ends of branches, c.1.7-2cm long; pedicel 2-3.5(-5)cm long, thickened gradually upwards; sepals 5, thickly coriaceous, oblong-lanceolate, 10-12 x 4-5mm, pointed, tip inflexed, margins at first held together by matted hairs, outer surface glabrous, inner densely and shortly pubescent, with elevated midrib; petals 5, whitish, glabrous, obovate to oblong-obovate, c.1.6-1.9cm x 8-9mm, 3-lobed, each lobe cut into smaller lobes, each petal +- holding a group of c.10 stamens by its incurved lower margins; stamens c.55, septulose-hispid, c.10 encircling each appendage of the torus and 1 opposite each sepal; filaments expanded and compressed towards base, incurved towards apex, 6-8mm long, obliquely attached to base of anther; anthers linear, 3.4-3.6 x 0.5-0.6mm, opening by terminal cleft; appendages 5, opposite petals, compressed-ovoid, c.1.5-2mm long, obtuse, obliquely ascending. Ovary densely covered with short, appressed hairs, broadly ovoid, c.3mm long, 3-ribbed by the decurrent style-bases, 3-celled, each cell with 2 pairs of ovules pendulous from near apex; styles 3, laterally compressed, narrowed upwards to punctiform stigma. Capsule almost woody when dry, subglobose, 3-ribbed, 2-3.5cm diam., 3-celled with 2 of them abortive, and 1 with a single seed, +- loculicidally dehiscent, with persistent, curved central axis; seed ovoid, c.2.5 x 1.5cm, except for hilum which is completely covered by reddish arillus, hilum just below apex, circular, 3-5mm diam.

Rainforest; Queensland, Australia [Cook District, Gadgarra (State Forest Reserve 310 – Windin & Swipers Logging Areas), Boonjie, Topaz, Millaa Millaa] (Smith 1956).

PERNETTYA

(Ericaceae)

Pernettya furens *(Hook. ex DC.) Klotzsch* **(P. furiens** *(Hook. et Arn.) Klotzsch***; P. insana** *(Molina) Gunckel***; Gaultheria furiens** *(Hook.) Hook. et Arn.***; G. insana** *(Molina) Middleton***)** – hierba loca, hued-hued, hysh-hued

Pernettya parvifolia *Benth.* – hierba loca, taglli

Pernettya prostrata *(Cav.) Sleumer* – macha-macha

P. furens of Chile and P. parvifolia of Ecuador are known to produce a drastic intoxication following ingestion of the berries. The effects are said to resemble those of **Datura**, affecting motor coordination and causing confusion, delirium, hallucinations and 'madness'. Though their toxicity is well known locally, these plants seem to have no other uses (Ott 1993; Schultes & Hofmann 1980, 1992). In Bolivia and Colombia, P. prostrata is also known to cause dizziness and intoxication if the fruits are eaten; children have died from this (Altschul 1967). In areas where San Pedro is consumed [see **Trichocereus**], a Pernettya sp. known as 'toro-maique' is sometimes consumed with it. Also, in Chile, Pernettya spp. including P. mucronata and P. myrtilloides have been used in the making of chicha [see *Methods of Ingestion*] (Rätsch 1998).

Overdose of toxic Pernettya spp. from eating the sweet, insipid berries induces salivation, vomiting, colic pains, depressed respiration, debility, collapse and even death (Luteyn ed. 1995).

P. furens aerial parts have yielded sesquiterpenes – pernetic acids A [0.0092%], B [0.00025%], C [0.00022%], D [0.00085%] and E [0.0008%], pernetic acid A methyl ether [0.0004%], pernetol [0.00003%] and pernetal [0.00006%] (Hosozawa et al. 1985), as well as the flavonoid quercetin (Buckingham et al. ed. 1994).

P. parvifolia has yielded toxic glucosides, andromedotoxins [grayanotoxins; see Rhododendron in *Endnotes*] (Lewis & Elvin-Lewis 1977).

Pernettya furens is a bushy herb 60-120cm tall, wider than tall. Leaves alternate, persistent, ovate to narrowly so or elliptic, 2.5-5cm long, leathery, finely toothed and lightly bristly-hairy; stipules none. Flowers 6-9mm long, 1 or more in nodding inconspicuous terminal racemes or panicles 3-4cm long; calyx persistent, lobes 5, broad, often ciliolate; corolla urceolate, white, lobes 5, very short, recurved; stamens 10, included, filaments dilated below; anthers 2-celled, mostly oblong or oval, appendaged at apex, dehiscing apically. Ovary superior, sessile, 5-celled, usually spheroidal; ovules numerous, anatropous; style columnar; stigma minute. Fruits nodding, smooth, globose or subglobose, brownish-red, c.5mm long. Fl. late spring-early summer.

Central Chile, coastal zone.

Pernettya spp. are cultivated in Europe in rock gardens. Propagate by seed, suckers or layering in spring, or from cuttings in late summer. Grow in a neutral to acid soil, with moderate light, keeping moist (Beckett ed. 1994; Small 1914).

PETALOSTYLIS

(Leguminosae/Caesalpiniaceae)

PETALOSTYLIS CASSIOIDES

Petalostylis cassioides *(F. Muell.) Symon* **(P. labicheoides var. cassioides** *(F. Muell.) Benth.***; P. labicheoides var. microphylla** *Ewart et Morrison***; P. millefolium** *E. Pritz.***; P. spinescens** *E. Pritz.***; Petalogyne cassioides** *F. Muell.***)** – butterfly bush

Petalostylis labicheoides *R. Br.* **(Petalogyne labicheoides** *(R. Br.) F. Muell.***)** – butterfly bush

These Australian shrubs are not recorded as having any ethnobotanical uses; however, they do yield some interesting alkaloids.

P. cassioides stem and leaf has yielded 0.44-0.47% *tryptamine*, 0.052-0.078% of a mixture of *DMT* and *tetrahydroharman* (Johns et al. 1966a), and *melatonin* (Shulgin & Shulgin 1997). Test material in regards to *tryptamine*, *DMT* and *tetrahydroharman* levels quoted, was collected in Oct. 1965. Although the levels of the last two alkaloids were low, it is possible that harvest at different times of year may yield higher concentrations or different alkaloidal proportions.

P. labicheoides has yielded *tetrahydroharman* (Badger & Beecham 1951). Leaf, harvested in June [from Miles, Qld], gave strong positive reactions for alkaloids; bark gave weaker reactions (Webb 1949).

Petalostylis labicheoides is an erect bushy shrub, nearly glabrous, somewhat glaucous, 1-3m tall; stems often pruinose, semi-deciduous; young shoots minutely silky. Leaves alternate, imparipinnate, sparsely to densely pubescent; rachis 1.5-6cm long; pinnae 5-21(-30 or more), mostly alternate, appearing opposite at distance, with an odd terminal one, lanceolate to elliptic or oblong-oblanceolate, 15-30mm x 4-8mm, apex acuminate to mucronate, narrowed at base, sparsely hairy, thick, somewhat concave, midrib only conspicuous beneath; stipules narrow and deciduous. Inflorescence a short, axillary raceme, bracteate, 1-5-flowered; sepals 5, 8-10mm long, unequal, scarcely united at base, lanceolate, imbricate, acute, green, glabrous; petals deep yellow, 5, 1 with reddish markings, nearly unequal, ovate to obovate, 15-20mm long, shortly clawed, spreading; fertile stamens 3, 5-7mm long, dehiscing by longitudinal slits; staminodes 2, small. Ovary +- sessile, appressed-pubescent; ovules 4-6; style deep yellow, oblique, petaloid, 8-10mm x 3-5mm, saccate immediately above ovary, with 3 erect lobes, 2 short ones in front, the 3rd much longer, concave, the midrib prominent inside and terminating at apex in a small stigma. Pod 2-3cm long, erect, flat, +- oblong, +- leathery, oblique, elastically dehiscent; stipe 10-20mm long; seeds few, ovate-oblong, compressed, oblique, shiny, arillate, separated by pithy partitions. Fl. spring.

On sand plains, dune fields, rocky ridges; Northern Territory [Dampier's Archipelago & Nichol Bay], Queensland [rare], New South Wales [n.w. & c.w. slopes, n.w. & s.w. plains], South Australia [Akava River, Mt Serle & towards Spencer's Gulf], n.w. Western Australia.

P. cassioides is essentially very similar to the above, but with 11-80 leaflets, obovate or oblong, obcordate or suborbicular, apex rounded or obtuse, emarginate, retuse or shortly mucronate, 0.2-1.8cm long; leaf rachis 1.5-14cm long.

On sand plains, stony plains, sandstone and rocky outcrops, scree slopes, gravel and along creek beds; WA, n.w. SA, n.w. Qld [Sturt's Creek & Gulf of Carpenteria], NT [near Alice Springs] (Bentham 1864; Harden ed. 1990-1993; Johns et al. 1966; Ross 1998).

PETROSELINUM

(Umbelliferae/Apiaceae)

Petroselinum crispum *(Miller) Nyman ex A.W. Hill* **(P. sativum** *Hoffm.***)** – parsley, persil

Petroselinum crispum ssp. tuberosum *Bernh. ex Rchb.* – Hamburg parsley

Folklore regarding parsley in England is mostly of rumours related to women, the devil, and bad luck. It was said that the seed must visit with Satan numerous times before it sprouts, so that he may have his share. This belief probably derives from the long and sporadic germination of parsley seed. It was also said that a girl who sowed parsley seeds, or picked parsley leaves, would become pregnant as a result. Girls were reputed to be born under parsley plants, which in Sussex, were said to have been given to women by faeries. The herb is said to be best cultivated by a woman, or by members of a household of which a woman is head. It was believed to be bad luck to be given parsley. If a parsley plant was transplanted, it was claimed that the death of the entire household of the person responsible would follow (Le Strange 1977; Opie & Tatem 1989).

Parsley [presumably the seed] was reputedly used in witches flying ointments [see *Methods of Ingestion*] (Rätsch 1992). In ancient Greece, tombs were bedecked with parsley, the 'herb of death', which was associated with Archemorus and Persephone. They also used the herb medicinally, crowned victorious athletes with it, and fed it to their war-horses. The Romans were the first to use it as food – they consumed the foliage regularly in large amounts, and made garlands of it for banquet guests to counter strong odours and allay intoxication. Some have said that eating the seeds "helpeth men that have weyke braynes to beare drinks better". The seeds were also eaten by both men and women to increase fertility (Bremness 1988; Chevallier 1996; Cunningham 1994; Le Strange 1977). This is interesting, as the leaves are reputed traditionally [in England] to be abortifacient when eaten, or when the leaf juice is applied to the mouth of the womb (Opie & Tatem 1989).

The Lahu of n. Thailand eat P. crispum seeds to 'help the spirits make the medicine work' in cases of intestinal pain, where a mixture of Carica papaya, Cucurbita spp. [see *Endnotes*] and Sanseviera trifasciata is administered; alternately, seeds of **Lactuca** may be chewed for the same purpose (Anderson 1993).

The leaves, root and seeds are used to treat urinary infections, stones and gout, and as an antirheumatic, galactagogue, emmenagogue, uterotonic, digestive and diuretic. They also have antioxidant and antihistamine properties. The leaves may be used to freshen the breath, as a poultice for sprains and cuts, and as a hair, skin and eye tonic. The seeds should not be consumed by pregnant women, or those with kidney problems (Bremness 1994; Chevallier 1996; Mabey et al. ed. 1992; Polunin & Robbins 1992). It has been suggested that the essential oil of the seed may be ingested as a stimulant-psychedelic, with likely undesirable side-effects (Gottlieb 1992), as parsley seed oil is highly toxic. The oil [at least some batches] does have strong 'hallucinogenic' activity comparable to that of nutmeg [see **Myristica**], though subjectively it feels much harsher and more toxic (Torsten pers. comm.). Apparently, the root of P. crispum ssp. tuberosum and the leaves of P. crispum ssp. crispum have been smoked for their effects. The essential oils have been used in the synthesis of psychotropic *phenethylamines* (Rätsch 1998).

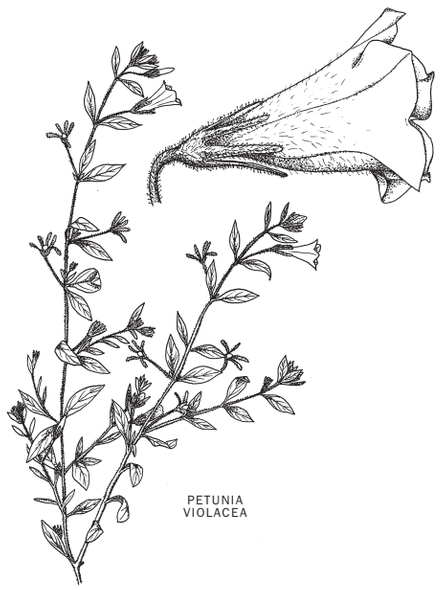
P. crispum leaf contains vitamins A & C, iron, manganese, calcium, phosphorous, flavonoids and a glycoside, as well as small quantities [c.0.7% w/w] of a pale yellow or greenish essential oil. The essential oil comes in three chemotypes – one is dominant in *myristicin* [20-85%], with 0-18% *apiole*, 1-23% *1-allyl-2,3,4,5-tetramethoxybenzene* and 0.3% *elemicin*; one is dominant in *apiole* [58-80%], with 9-30% *myristicin* and traces-6% *1-allyl-2,3,4,5-tetramethoxybenzene*; and one is dominant in *1-allyl-2,3,4,5-tetramethoxybenzene* [52-57%], with 26-37% *myristicin* and no *apiole*, or traces of it; p-methyl-*acetophenone*, 4-isopropenyl-1-methylbenzene, phellandrene, *pinene*, myrcene, terpenolene, menthatriene, carotel and many other compounds are also found in the leaf oils. A yellow, amber or brownish essential oil is concentrated in the seeds [2.4-3.2%], and consists mainly of *apiole* [18%] and *1-allyl-2,3,4,5-tetramethoxybenzene* [38%], as well as 1% *myristicin*, 20% α-*pinene*, 16% β-*pinene* and volatile fatty acids (Battaglia 1995; Harborne et al. 1969; Kasting et al. 1972; Lawless 1995; MacLeod et al. 1985; Rajkowski 1964; Shulgin 1967). The plant also contains furocoumarins which can cause photosensitisation (Culvenor 1970).

Petroselinum crispum is an erect annual or biennial glabrous herb; stem terete, solid, at anthesis up to 1m tall, much-branched, branches ascending. Leaves deltoid or triangular in general outline, 3-pinnate; the numerous leaflets 10-20mm, linear to cuneate-obovate, variously toothed or lobed, often crispate in cultivars. Umbels 5-8cm wide, long-peduncled, terminal and lateral, flat-topped; rays 8-20, about equal; umbellets many-flowered; involucel of 4-6 lanceolate bracts shorter than the pedicels; bracts 1-3, entire or 3-fid; bracteoles 5-8, linear-oblong to ovate-cuspidate; sepals none or minute; petals 5, usually +- 3-lobed, yellow or greenish-yellow, emarginate; stamens 5. Carpels (1-)2; styles (1-)2, often with thickened base; ovule pendent, 1 in each loculus. Fruit broadly ovate, 2-3mm long, flattened laterally, constricted at the commissure, ribs 5, narrow, prominent, filiform; oil-tubes solitary in the intervals, 2 on the commissure; carpophore cleft to the base.

Origin uncertain, probably s.e. Europe and w. Asia; cultivated as a culinary herb, also naturalised in some parts of Europe (Gleason 1952; Tutin et al. ed. 1964-1980).

PETUNIA

(Solanaceae)



Petunia violacea *Lindley* **(P. dichotoma** *Sendt.***; P. integrifolia** *(Hook.) Schinz et Thell.***; P. phoenicia** *D. Don, ex Loudon***)** – shanin, petunia

This herb is said to have been used as a 'hallucinogen' in highland Ecuador. Its consumption is said to cause a sensation of flying, a phenomenon sometimes attributed to the hallucinogenic tropane alkaloids [such as *hyoscine*]. Substantiating evidence has so far proven elusive (Butler et al. 1981; Schultes & Hofmann 1980).

P. violacea leaves were found to contain no volatile alkaloids, in an early screening alongside some **Nicotiana** spp. (Kovalenko 1934); a later alkaloid screening also found no alkaloids in stem or leaf of Uruguayan plants [harv. Dec.] (Fong et al. 1972), and neither did a later analysis of cultivated material of horticultural origin [seeds, roots, stems and flowers from plants at different stages of development] (Butler et al. 1981). As P. integrifolia, it has yielded the ergostane-type steroid petuniasterone N [c.0.15%] from the leaves (Elliger et al. 1989). P. violacea has been shown to strongly inhibit human plasma AChE (Orgell 1963b).

P. x hybrida flowers have yielded cyanidin, delphinidin, malvidin, petunidin, paeonidin, cinnamic acid and flavones (Hess 1964; Steiner 1970); leaves accumulate flavonol glycosides and anthocyanins, via activity of the enzyme flavanone-7-O-glucosyltransferase (Durren & McIntosh 1999). Leaves and stems have yielded ergostane-type steroids, including petuniasterone A, petuniasterone N [c.0.02%] and petuniasterone B 22-O-((methylthio)-carbonyl)acetate (Elliger et al. 1988, 1989).

Petunia violacea is a perennial herb (annual in cultivation), branching from the base, ascending or semierect, glandular-pubescent, to 60cm tall. Leaves alternate (or opposite apically), entire, ovate to ovate-lanceolate, apex acute, base attenuate, glabrous or slightly pilose, to 15-50 x 5-20mm; pseudopetiole winged. Flowers solitary in axils of terminal leaves, forming racemose-like clusters; pedicels pubescent, 1-4cm long; calyx campanulate, hirsute-glandular, deeply pentasect, with tube 2-3mm long, segments linear, somewhat widened towards apex, obtuse or semiacute, 5-17mm long x 1-1.5mm wide; corolla violet, pubescent, infundibuliform, with tube wide and limb open 25-40mm long x 25-30mm wide; stamens unequal. Capsules globose-ovoid, 6-7mm long; seeds subglobose, fine-

ly reticulate.

Brazil, from Paraná through Rio Grande to Sul, Paraguay, Uruguay and n.e. Argentina; frequent in Entre Rios (Burkart 1979).

Petunias are commonly cultivated the world over, and most cultivated varieties [P. x hybrida] have been believed to be hybrids between the S. American natives P. axillaris [white flowers] and P. violacea [purple flowers] (Haegi et al. 1982). However, others believe that P. axillaris and P. violacea may be synonymous, with P. violacea representing a variant. Not only that, but many plants circulated in horticulture as 'P. violacea' may in fact be incorrectly named hybrids based on P. axillaris and other species (Sink 1984).

PEUCEDANUM

(Umbelliferae/Apiaceae)

Peucedanum decursivum *(Miq.) Maxim.* **(P. melanotilingia** *(Boissieu) Boissieu***; P. porphyroscias** *(Miq.) Makino***; Angelica decursiva** *(Miq.) Franch. et Sav.***; Pimpinella decursiva** *(Miq.) Wolff.***; Porphyroscias decursiva** *Miq.***; Selinum melanotilingia** *Boiss.***)** – zi-hua qian-hu, nodake, shikazenko

Peucedanum dhana *Wall.*

Peucedanum japonicum *Thunb.* **(P. litorale** *Vorosch. et Gorovoj***)** – fang-k'uei, fang kui

Peucedanum ostruthium *(L.) W. Koch* **(P. imperatoria** *Endich.***; Imperatoria ostruthium** *L.***; I. trilobata** *Gilib.***; Selinum imperatoria** *Crantz***; S. ostruthium** *Wallr.***)** – masterwort, hog fennel

Peucedanum verticillare *(L.) Koch. ex DC.* **(P. altissimum** *(Miller) Thell., non Desf.***; Tommasinia altissima** *(Miller) Thell.***)** – hog fennel

The root of 'fang-k'uei', P. japonicum, is used in TCM as a sedative, eliminative and diuretic, which acts as a tonic with extended use. It is also used to treat epilepsy, hernia, and other disorders. However, its use is not recommended in excess, or by feverish people, as it reputedly then "causes one to be delirious and see spirits" and "act somewhat like mad" (Li 1978). P. ledebourielloides and P. wawrii roots may have been used as 'fang-feng' in the past [see **Siler**] (Wang & Lou 1989). Root of P. decursivum is also used by the Chinese as a nervine, aphrodisiac, ch'i tonic (Rätsch 1992), analgesic, expectorant, antitussive and antipyretic, in doses of 5-10g (Keys 1976). A fermented root extract of P. ostruthium is said to be euphoric and analgesic, and treats toothache, bronchial catarrh and stomach upsets. Its leaves are used to flavour some cheeses (Chiej 1984). In the Himalayas, roots of P. dhana are taken as a tonic (Usher 1974).

P. decursivum root has yielded coumarins – decursidin, bergapten, nodakenetin, nodakenin, 3'(S)-senecioyloxy-4'(R)-OH-3',4'-dihydroxanthyletin, 3'(S)-OH-4'(R)-senecioyloxy-3',4'-dihydroxanthyletin and 3'(S)-angeloyloxy-4'(R)-acetoxy-3',4'-dihydroxanthyletin (Sakakibara et al. 1982).

P. japonicum root has yielded coumarins, including peucedanol, hamaudol, (+)-samidin, khellactone-derivatives, bergapten (Hata et al. 1968; Shigematsu et al. 1982), coumarin [sedative hypnotic in large doses – see **Justicia**] and furocoumarin; and 3-methyl-2-butenoic acid has also been found in the plant (Buckingham et al. ed. 1994; Schultes & Hofmann 1980). cis-Diisovalerylkhellactone and disenecioylkhellactone from this plant showed anorexic activity (Hsu 1987).

P. ostruthium has yielded aviprin, ostruthin, ostruthol, oxypeucedanin, pabulenol, pabulenone, peucenin, imperatorine, ostruthine, ostrol, Z-ligustilide, senkyunolide, emetine, tannin and starch (Buckingham et al. ed. 1994; Chiej 1984; Gijbels et al. 1984).

P. verticillare aerial parts [harv. late Jun., central Italy] yielded 0.05ml essential oil per 100g [w/w], consisting mostly of sabinene [39.6%] and (E)-*anethole* [29.5%], as well as epi-*camphor* [7.8%], α-*pinene* [6.3%], α-phellandrene [5.6%], β-myrcene [4.7%] and traces of other compounds; fresh fruits [harv. mid Jul., same location] yielded 0.125ml/100g [w/w], consisting mostly of sabinene [63%], as well as α-phellandrene [9.3%], β-myrcene [8.1%], nerol [3.5%], (E)-*anethole* [1.8%], β-*pinene* [1.6%] and traces of other compounds; dry fruits [dried on plant; harv. Aug. & Sep., same location] yielded 0.21ml/100g, consisting mostly of β-caryophyllene [24.2%] and α-phellandrene [20.8%], as well as (Z)-β-farnesene [12.8%], β-bisabolene [9%], β-cubebene [7.5%], caryophyllene oxide [6.7%], trans-α-bergamotene [5.3%], geranyl acetate [5%], γ-terpinene [3.8%], (Z)-β-ocimene [2.7%] and cis-caryophyllene [2%] (Fraternale et al. 2000).

Some members of the genus Peucedanum contain *scopoletin* (Buckingham et al. 1994).

Peucedanum japonicum is a rather stout, glabrous, perennial herb 60-100cm tall. Leaves long-petiolate, 1-2-ternate, 10-35cm long incl. petiole, the leaflets obovate-cuneate, 3-6cm long, 2-4cm across, petiolate or sessile, often slightly 3-lobed at apex; pinnules dentate or slightly lobed; cauline leaves reduced upwards; petioles 10-20cm long, sheathing at base. Umbels compound; peduncles 3-10cm long; involucres deciduous, linear-lanceolate, 5-8mm long, pubescent; rays 15-30, 1-5cm long, spreading-ascending, subequal; involucels several, linear-lanceolate, 5mm long, pubescent; umbellules 1cm long; flowers polygamous, white; calyx teeth prominent to obsolete, hirsutulous, 1cm long; petals ovate, with narrower inflexed apices dorsally, glabrous to pubescent; stylopodium conical. Fruit oblong-ovate, dorsally-compressed, 4-6 x 2-4mm, pubescent, dorsal ribs filiform, not winged, lateral ribs winged, shorter than body; vittae 3-5 in the intervals, 8-10 on the commissure; seed face slightly concave.

Maritime areas, along seashores; Japan, the Ryukyus, China, Philippines, Taiwan, Lanyu Island (Flora of Taiwan Editorial Committee ed. 1977).

PHALARIS

(Gramineae/Poaceae)

Phalaris angusta *Nees ex Trin.* **(P. intermedia** *Bosc. ex Poir.* **var. angusta** *Chapm.***)**

Phalaris aquatica *L.* **(P. tuberosa** *L.***)** – Toowoombah canary grass, large canary grass

Phalaris aquatica *L.* **x arundinacea** *L.* – ronpha grass

Phalaris arundinacea *L.* – reed canary grass

Phalaris brachystachys *Link.*

Phalaris canariensis *L.* – canary grass

Phalaris caroliniana *Walt.* **(P. intermedia** *Bosc. ex Poir.***)**

Phalaris coerulescens *Desf.* – blue canary grass

Phalaris minor *Retz.* – canary grass

Phalaris paradoxa *L.* – paradoxa grass

Phalaris stenoptera *Hack.* **(P. aquatica var. stenoptera** *(Hack.) Burkart***; P. tuberosa var. stenoptera** *(Hack.) Hitchc.***)** – Harding grass

Phalaris truncata *Guss. ex Bertol.*

Phalaris spp. – phalaris grass

Phalaris grasses [usually P. aquatica or P. arundinacea] have long been popular grown as stock fodder for grazing animals. Some species, such as P. minor and P. canariensis, are grown for bird seed [hence, 'canary grass']. However, Phalaris spp. [particularly P. aquatica and P. arundinacea] are known to cause a neurological intoxication of variable duration known as 'Phalaris staggers', under some conditions, in sheep and cattle. Also known is a cardiac disorder often called 'sudden death syndrome', though death does not always result. These poisonings were thought to have been caused by the psychoactive *tryptamine* alkaloids present in these grasses [due almost entirely to questionable research conclusions by C.H. Gallagher – see Festi & Samorini 1994b and Trout ed. 1998]. Occasionally death occurs, in animals that have eaten a particularly large patch, or have been grazing it over a long period. These deaths are now known not to be directly related to the *tryptamine*-content of these grasses. The presence of 3-methylindole and N-methyl-*tyramine* has also been suspected as a causative agent. It is also known that potentially lethal levels [for grazing animals] of nitrate [c.0.29%] and HCN [0.02-0.036%] may be accumulated in some stages of growth [eg. HCN may be produced primarily in first cuttings of young growth]. The tryptamines do, however, appear to be responsible for the neurological symptoms of the intoxication, as well as causing diarrhoea; these symptoms are observed when indole alkaloid content exceeds 0.2% d/w. *Hordenine* is responsible for the unpalatability of some strains. P. aquatica x arundinacea, P. angusta, P. brachystachys, P. caroliniana and P. minor also produce intoxications in livestock (Bourke et al. 1988, 1992b; Cheeke 1995; Festi & Samorini 1994a, 1994b; Hungerford 1990; Oram 1970; Parmar & Brink 1976; Rendig et al. 1976; Ruelke 1961). P. coerulescens and P. paradoxa are suspected of having caused the death of horses in Australia, although they appear not to be toxic to ruminants (Anderton et al. 1998; Bourke et al. 2003). Several 'quick tests' for alkaloid concentration in Phalaris spp. have been devised (Frelich & Marten 1973), but to the non-chemist, it would seem simpler to extract a sample of grass to a freebase alkaloid mix, and evaluate alkaloid quantity from the end yield.

The *tryptamine*-alkaloid content, however, is the reason these grasses deserve extra attention, as several species have yielded useful quantities of the tryptamines *DMT* and *5-methoxy-DMT* [*5-MeO-DMT*]. Experiments with smoking dried young plants of P. aquatica 'AQ-1' [see below] cut from the second re-growth resulted in barely perceptible effects. However, psychedelic effects could be obtained by inhaling vapour emitted from heated fresh plant cuttings [these were, of course, not heated to the point of combustion] (Festi & Samorini 1994a). Some of the more potent strains of P. aquatica and P. arundinacea, rich in *5-MeO-DMT*, have only required a simple 1-shot extraction [solvent extraction, or juicing the shoots, the extract then being dried] to yield a visionary smoking material (DeKorne 1994). However, apart from Jim DeKorne who first reported this, I have not heard of anyone meeting with any success via this route. It seems best to go to a bit of extra effort and extract the alkaloids to a pure or near-pure state [see *Producing Plant Drugs*]. P. aquatica and P. arundinacea have also been used as constituents of ayahuasca analogues [see *Methods of Ingestion*], combined with **Peganum** harmala seeds, to

produce a powerful experience. It seems that *5-MeO-DMT*, when present in higher amounts, can make for a physically unpleasant and extremely intense experience via this route (DeKorne 1994, ed. 1996; pers. comms.).

The first reported use of Phalaris spp. in an ayahuasca analogue was an experiment conducted by two Italian researchers, using an extract of 4.5g **Peganum** harmala seeds [consumed first] with an extract of c.400g fresh P. aquatica 'AQ-1' [consumed 20mins later], for each dose. 'AQ-1' is a wild Italian strain named by Giorgio Samorini, who found it growing near Bologna. This has proven to be a potent strain [see below], which was not known at the time of the first bioassay. Effects were noted 30mins after consumption, and seemed to then diminish, followed by a strong return of effects an hour later. Some 40mins after this point one of the researchers became unconscious for an extended period [not returning to normal for some 13hrs after ingestion]. His symptoms, observed by his friend and co-bioassayist, included "symptoms of adrenergic activation with strong mydriasis, muscular hypertonicity [particularly in the nape and the back], muscular clonus, tremors, exaggerated reflexes." Needless to say this was a most distressing experience for both involved. A second bioassay using an extract of c.2.5g P. harmala seeds and an extract of c.60g fresh 'AQ-1' was much more manageable, and without adverse reactions. It has been thought that any *5-MeO-DMT* present in the 'AQ-1' might have produced the adverse reaction of the first bioassay (Festi & Samorini 1994a; Samorini pers. comm.), though it is unusual that only one of the researchers experienced these effects. The symptoms seem to suggest 'serotonin syndrome' [see *Influencing Endogenous Chemistry*], which might perhaps be induced by an overdose of *5-MeO-DMT* with MAOI (pers. obs.).

P. brachystachys and P. stenoptera have also been used successfully in ayahuasca analogues (Green 1999a, 2000). It is not recommended to use the fresh juice of Phalaris spp., as many bioassays have indicated increased toxicity ["many more side-effects and toxic 'hangover' after-effects"] (Trout ed. 1998). One person did not note side-effects, but did experience a "very powerful, very short, psychedelic journey" after ingesting 1tsp fresh P. aquatica juice with 3g **Peganum** harmala seeds. This psychonaut noted that the experience was very different from that of *DMT* or *5-MeO-DMT*, an assertion backed up by friends who later tried the same preparation. These effects were not noted in summer harvests, or if the juice extract was dried; they were noted to be present when the night greenhouse temperature fell below 60ºF. Freezing the extract immediately after juicing preserved this unique activity. It was proposed that the subjective effects were due to an unknown *tryptamine* (Green 2000), though one is forced to wonder whether *bufotenine* may be responsible.

I have experienced 'threshold' effects from ingesting a water/lemon juice [7:3] extract of 3g ground **Peganum** harmala seed, with a similar extract of P. aquatica [10g dry young shoots]. An enhancement of sound-perception and awareness of the space around me was noticed after 20-30mins. The effects progressed little further, though another 30mins later when I was lying down with eyes closed, I experienced several delightfully-pleasant 'rushes' of mild psychedelic energy tingle up my spine and burst in my head. The effects receded almost imperceptibly over the next hour or two, and no after-effects were noted. The preparation did not cause nausea and felt 'friendly' to my body and mind. The grass had been cultivated from rhizome-cuttings [taken from escaped P. aquatica growing near Dandenong Creek, Victoria, Australia] in a 30cm diam. pot with fertile, moderately well-drained soil; it was grown largely in semi-shade, fertilised every month or so with dilute urine, and generally ignored except for weeding. After several initial clippings, I allowed the plant to mature and flower (it very much resembled P. minor, and I developed a suspicion that P. minor might be a younger growth-form of P. aquatica, as the parent of these rhizomes was definitely P. aquatica; I also wondered if it was possible that the continuous clipping of the plant had simply stunted the stature of its flowers when eventually allowed to mature). After cutting the mature growth, I again began collecting the young regrowth in the mornings, and saving the dried foliage in a zip-lock bag until I had enough to experiment with. This took many months, as the size of the plant was restricted to the one pot.

P. angusta contained an unidentified *tryptamine* that was not *5-MeO-DMT*, but gave a similar colour reaction (Festi & Samorini 1994a).

P. aquatica has yielded 0.03-0.178% alkaloids, containing *DMT*, *5-MeO-DMT* and *bufotenine*; the amount of *bufotenine* is minor, and the other two compete for status as the major alkaloid. The highest yields in these tests were from the 'S184' strain from Crete, which yielded mostly *5-MeO-DMT*, and only 5% of the alkaloids was *DMT* (Culvenor et al. 1964; Oram & Williams 1967). 'Australian commercial' P. aquatica has yielded 0.1% *DMT* and 0.05% *5-MeO-DMT*, with traces of *tryptophan*, *tryptamine*, *serotonin*, *5-MeO-tryptamine* and *bufotenine*; seedlings only contained *DMT* and *5-MeO-DMT* (Baxter & Slaytor 1972a, 1972b). However, in a more detailed assay, 7 day-old seedlings of this cultivar were shown to contain 23 different bases, of which 15 were identified. *DMT* was identified as the major alkaloid [300nmol/100 seedlings], with other compounds identified as *5-MeO-DMT*, 5-MeO-*NMT*, *5-MeO-tryptamine*, *bufotenine*, 5-OH-*NMT*, *NMT*, *serotonin*, *tryptamine*, *tryptophan*, 5-MeO-*tryptophan*, *gramine*, 3-aminomethylindole, 3-methylaminomethylindole, and indole-3-aldehyde (Mulvena & Slaytor 1982). Yields of up to 0.3% *DMT* have been reported in Australia (Hungerford 1990); though the wild Italian 'AQ-1' strain has yielded c.1% alkaloids [mostly *DMT*] (Festi & Samorini 1994a, 1994b). Strain 'Sirolan' yielded only 0.0004-0.0005% alkaloids [w/w]; strain 'Sirosa' yielded 0.0029% alkaloids [w/w]; and slow-growing winter strains yielded 0.0092% alkaloids [w/w] (Skerritt et al. 2000). The 'Sirocco' strain, growing in southern Australia, yielded *5-MeO-DMT* as the major alkaloid. Several South Australian strains – 'GB81', 'Seedmaster', 'Sirocco', 'High alkaloid' and 'Low alkaloid' – yielded 0.001-0.06% alkaloids, highest with active growth after rain in autumn and early winter. All contained at least c.5% each [of total alkaloids] 2-methyl-THβC and 2-methyl-*pinoline*, though 'Seedmaster' contained higher levels of these compounds (Frahn & O'Keefe 1971). The species has also yielded N-methyl-THβC, *tetrahydroharman*, N-methyl-*tyramine* (Anderton et al. 1999; CSIRO 1990; Shulgin & Shulgin 1997; Vijayanagar et al. 1975), coerulescine and phalarine [see below] in smaller amounts (Bourke et al. 2003). Fresh samples contain higher proportions of *bufotenine* than dried samples (Culvenor et al. 1964). Grass may consist of c.80% water by weight (Trout ed. 1998).

P. aquatica has been observed infected with the ergot **Claviceps** phalaridis, of unknown chemistry and toxicology. As well as residing inconspicuously within the ovary of the flower, where it is not easily seen, autumn growth of the infected grass is also seen to bear intercellular hyphae of the endophyte in the vegetative growth (Walker 1970).

P. arundinacea has yielded [0-]0.004-1.19% alkaloids [clone '108-3' yielded the higher value; clone '255-10' gave 0.91%], though this has been said to range up to 2.75%; the major base in 'palatable' [to stock animals] strains is *gramine* [up to 0.3%], up to 0.07% *5-MeO-DMT* and no *DMT*; whereas 'unpalatable' strains contained up to 0.02% *DMT*, <0.01-1% or more *5-MeO-DMT* and no *gramine*; some strains yield only *DMT* (Barker & Hovin 1974; Barnes et al. 1971; Culvenor et al. 1964; Marten et al. 1973; Parmar & Brink 1976; Williams et al. 1971). It has also yielded *hordenine*, 5-MeO-*NMT* (Ghosal 1972; Wilkinson 1958), and c.0.0002% each of 2-methyl-*pinoline* and 6-MeO-2,9-dimethyl-THβC (Vijayanagar et al. 1975) – 2-methyl-*pinoline* sometimes may occur in higher concentrations [clones 'R37' and 'R52'], with little or no *5-MeO-DMT* and some *hordenine*. Plants producing *DMT* may also yield 2-methyl-THβC in varying ratios (Gander et al. 1976). In N. American plants, those with low *DMT*-content had high β-carboline levels, and vice versa (Bourke et al. 1988). In general, *DMT* and *5-MeO-DMT* were not found in plants of the same strain; in this case, *5-MeO-DMT* producers usually yielded 2-methyl-*pinoline* and *hordenine*, whilst *DMT* producers did not (Gander et al. 1976). Strain 'Ottawa Synthetic C' yielded 0.009% *hordenine* and lesser amounts of *gramine*, 6-MeO-2,9-dimethyl-THβC and n-octacosanol (Audette et al. 1970). Strain 'NRG 741' from Canada, collected after seeding, yielded 0.067-0.115% *5-MeO-tryptamine* and 0.059-0.063% *gramine*, whilst strain 'NRG 721' yielded 0.027-0.074% *gramine* and no *5-MeO-tryptamine* (Majak et al. 1978). The 'PI 172443' strain from Turkey ['Turkish Red'] showed an increase in *DMT* content on drying, which was stable over time; yet the 'PI 253317' strain from Yugoslavia ['Yugoslavian Fresh Cut'] showed highest *DMT* levels when fresh – on drying, total alkaloid levels decreased, as did the relative concentration of *DMT* (Appleseed 1993). Grass may consist of c.65-81% water by weight (Trout ed. 1998).

Traces of 5-methyl-*tryptamine*, 7-MeO-*gramine* and 5,7-dimethoxy-*gramine* have also been found in these two Phalaris spp. during some stages of growth (Festi & Samorini 1994a, 1994b).

P. brachystachys has been found to contain *DMT* in high concentration, as the sole alkaloid (Festi & Samorini 1994a). Greek plants have been found to give good yields of *DMT* (Green 1999a).

P. canariensis has been found to contain *DMT* as the major alkaloid, as well as *5-MeO-DMT* and traces of *bufotenine* (Festi & Samorini 1994a, 1994b); this species was consistently observed to have low alkaloid concentration in one study (Oram 1970).

P. coerulescens was found to contain *DMT* as the major alkaloid, with traces of *bufotenine* (Festi & Samorini 1994a, 1994b), though later work has given a different picture. This species recently yielded 2-methyl-THβC, possibly 2-methyl-*pinoline*, traces of *DMT* [in some samples], 0.001% coerulescine [a new oxindole], horsfiline [an oxindole – see **Horsfieldia**], and 0.003% of a new furanobisindole, phalarine. It was observed that a standard sample of *bufotenine* in aqueous methanol degraded rapidly at room temperature, suggesting that any *bufotenine* present in the plant extract may be hard to detect in some circumstances (Anderton et al. 1998, 1999a, 1999b; Bourke et al. 2003). Perhaps the differences in relative levels of *DMT* and the other alkaloids are related to the stage of growth of the plant material analysed (pers. obs.).

P. minor has been found to contain traces of *DMT* as the only alkaloid (Festi & Samorini 1994a).

P. paradoxa has been found to contain *DMT* as the major alkaloid, as well as *NMT* and traces of *bufotenine* (Festi & Samorini 1994a, 1994b). As with the closely-related P. coerulescens, recent analysis has shown other alkaloids to be more predominant – 2-methyl-THβC, phalarine and coerulescine, and methoxylated derivatives of all three (Bourke et al. 2003).

P. stenoptera has yielded 0-0.28% alkaloids, consisting of *5-MeO-*

DMT [major alkaloid], *DMT* and traces of *bufotenine*. Alkaloid peaks were often observed in September when grown in California (Festi & Samorini 1994b; Rendig et al. 1976; Trout ed. 1998). This species has been bioassayed in ayahuasca analogues, and observed to be c.1/3 as potent as Greek P. brachystachys (Green 1999a, 2000).

P. truncata has been found to contain *DMT* as the major alkaloid, as well as *5-MeO-DMT*, *NMT* and traces of *bufotenine* (Festi & Samorini 1994a, 1994b).

Oram assayed 33 strains of 14 Phalaris spp., finding all to contain tryptamines, though the identities of the species were not given (Oram 1970).

Cyanogenic compounds are usually present in Phalaris spp., but in levels too low to be of concern for human consumption, and they detoxify rapidly to trans-aconitic acid (Anderton et al. 1998, 1999; Festi & Samorini 1994a, 1994b). Apparently, the genes controlling *gramine* synthesis in Phalaris spp. are recessive to those controlling synthesis of other indoles (Trout ed. 1998); hence, breeding could perhaps adapt non-desirable *gramine*-dominant strains to desirable *tryptamine*-producers.

Recently, concerns have been raised by Dr. A.T. Shulgin and others regarding some of the β-carbolines present in Phalaris spp., which have close structural similarity to β-carbolines of demonstrated toxicity. In animal studies, 2-methyl-, 2,9-dimethyl- and 2-methyl-3,4-dihydro- β-carbolines have been shown to inhibit mitochondrial respiration (Albores et al. 1990; Matsubara et al. 1998). Also, (-)-(1S, 3S)-1-methyl-THβC-3-carboxylic acid has been shown to be neurotoxic to mature neurons, though promoting the survival of immature neurons (Brenneman et al. 1993). Although toxicity of the 1,2,3,4-tetrahydro-β-carbolines in Phalaris has not been demonstrated, there remains a possibility that they may be metabolised intraneurally to form neurotoxins (Shulgin pers. comm.; Trout pers. comm.).

Nitrogen [only in full light; best soil absorption from ammonium nitrogen], increased temperature, periods of water deprivation [growth after the drought is up to 3x more potent, though also contains greater levels of N-methyl-*tyramine*], and shading all increase alkaloid concentration in young growth. There are also large variations in alkaloid concentration over different times of day – *DMT* content [in shaded plants] is highest in early morning, whereas *5-MeO-DMT* is highest in late morning. In P. arundinacea, water stress and continuous harvests promote an increase in *gramine* levels, in *gramine*-producing strains. Also, clippings from the first regrowth after cutting-back have yielded higher alkaloid levels than the initial cutting [which may yield small levels of cyanogenic compounds, and is often deficient in *tryptamine* alkaloids]. Alkaloid levels decrease as the plant gets older. Young, chlorophyllous growth [upper 1/3 of leaf blades before solid stems have formed] is most potent; 7-day old plants have been most potent in regards to first harvest. Roots, stems, sheaths, lower portions of leaf blades, and older leaves yield negligible levels of alkaloids. Late summer to autumn is generally the best harvesting time. *Hordenine* is mainly present in leaf sheath and other parts, in later stages of growth. Drying reduces the alkaloid levels by up to 50%, with some exceptions [eg. 'Yugoslavian Fresh Cut' – see above] (Cheeke 1995; Culvenor et al. 1964; Festi & Samorini 1994a, 1994b; Hungerford 1990; Marten et al. 1973; Moore et al. 1967; Parmar & Brink 1976; Skerritt et al. 2000; Trout ed. 1998). Some research suggests that 'common' and older plantings of these grasses are more often found to be rich in alkaloids (Appleseed 1993).

Experiments with P. aquatica 'Australian commercial' suggest that the production of *5-MeO-DMT* and perhaps *DMT* might be self-limiting, as the latter alkaloid inhibits a *tryptophan* decarboxylase enzyme found in seedlings [as do *tryptamine*, *5-hydroxytryptophan*, indoleacetic acid and indole acetaldehyde] (Baxter & Slaytor 1972a). However, numerous potential metabolic pathways exist for the biosynthesis of alkaloids [such as *5-MeO-DMT*] in this species, and it is unclear what conclusions can be drawn from this (Baxter & Slaytor 1972b).

Phalaris aquatica is a tussock-forming perennial grass, spreading slowly by short rhizomes; to 2m tall. Tillers swollen at base; leaf blades 15-40cm x 4-15mm, flat, glabrous, greyish-green in older growth, young leaves rolled in bud, green; auricles absent, a pale greenish 'collar' at blade base; ligule white, translucent, 3-5mm long, longer than wide, rounded at apex; leaf sheath greyish-green, glabrous, round in cross-section – when cut through at base, exudes a pink sap (I have only noticed this in young plants, and present as more of a red stain). Inflorescence a dense, cylindrical, spike-like panicle 5-15cm x 10-15mm; spikelets of 3 florets, the fertile floret +- oval and laterally flattened, 5-7mm long, 2 outer glumes enclose floret, 2 minute sterile lemmas attached at base of fertile floret represent the 2 infertile florets; glumes laterally flattened, strongly keeled, winged on distal half, striped green and pale green or whitish, boat-shaped and equal in length, awnless; lemma covered with fine, loosely appressed hairs when young, at maturity shiny and smooth, cream to pale brown, awnless; anthers 3, yellow.

Native to Mediterranean region; introduced as a forage crop in US, Australia, S. Africa, Argentina and Uruguay, as well as other countries, now a widespread weed of roadsides, wetlands and waste ground.

Sow seed in a weed-free bed where they are to grow, in autumn or spring; grows in a wide range of soils, prefers sandy soil with clay subsoil [within 30cm of surface]; drought-tolerant; +- dormant in summer. Plants may take several years to become fully established (Lamp et al. 1990; pers. obs.).

Field identification in Australia might be hampered, in some instances, by the existence of a fertile hybrid between P. aquatica and P. minor, which originated in Queensland and has been proposed as a new species, P. daviesii (Blake 1956).

PHRAGMITES

(Gramineae/Poaceae)

Phragmites australis *(Cav.) Trin. ex Steud.* **(P. communis** *Trin.***; P. dioica** *Hack. ex Conert***; P. dioica** *Hack. ex Hicken***; P. maximus** *(Forssk.) Chiov.***; P. phragmites** *(L.) H. Karst.***; P. vulgaris** *(Lam.) Bonnet***; Arundo australis** *Cav.***; A. maxima** *Forssk.***; A. occidentalis** *Sieber et Schult.***; A. phragmites** *L.***; Zizania effusa** *Munro***)** – common reed, reed grass, ditch reed, carrizo, lu-ken, lu-jen, bous, ghab, qoboi, qasba

Common over much of the world, P. australis is used to make thatching, mats, and brooms. The herb is sometimes now planted to treat sewage organically by absorbing impurities from water-sources. Various native American groups have cooked the seeds into a gruel, boiled the young shoots as a vegetable, ground the rhizomes into flour, and eaten the sap. In Japan, young shoots are cooked and eaten as a vegetable, and the manna-like gum that exudes from the stem is also eaten. The rhizome in TCM is considered sweet and cold in energetics, with affinities for the lungs and stomach. It is used to treat nausea, urinary problems, arthritis and thirst from fever; it may also treat coughs, excess phlegm, hiccoughs, lung pain and fish-poisoning [medicinal dose – 15-60g] (Bremness 1994; Duke 1983; Hsu et al. 1986; Kokwaro 1995; Tierra 1988). In parts of Arabia, the rhizome is used in folk medicine as an antiemetic, antipyretic, diaphoretic, diuretic and stomachic (Wassel et al. 1985). In southern Africa, the rhizome ['qoboi'] has been reported as an ingredient of a compound drug ['sehoere' – see *Methods of Ingestion*] consumed in intoxicating ritual feasts by the Basuto (Laydevant 1932). Seri shamans of Sonora prepare tubes of P. australis stem, filled with a special powder prepared with the aid of 'ikkor', an 'invisible power' which controls the spirits of plants. These tubes are hired out as a good luck fetish, or as a charm to cure illness (Felger & Moser 1974).

The rhizomes of P. australis have been bioassayed with successful results in ayahuasca analogues [see *Methods of Ingestion*] in doses of 45g dry and 25-50g fresh, boiled 15-30 minutes in acidified water, and consumed with extracts of **Peganum** harmala seeds. The extract has a sweetish taste, unlike many other analogue plants. Some others have had little or no success with this plant. In some cases this might be attributed to the use of purchased rhizome which was possibly old and relatively inactive. I have communicated with individuals who have bioassayed the rhizome in large amounts with **Peganum** harmala and experienced no effects. It would seem that a great degree of natural variation would be inherent in different strains across the world. Optimum harvest time, in regards to *DMT* content, also needs further investigation (DeKorne ed. 1996; pers. comms.).

P. australis rhizomes showed the presence of 0.003-0.01% alkaloids in an alkaloid screening (Hultin & Torssell 1965); rhizomes from Egypt were shown to contain *gramine*, *DMT*, *bufotenine*, 5-MeO-*N-methyltryptamine* and an unidentified base (Wassel et al. 1985). Swertiajaponin, isoswertiajaponin, 7-O-methylrutin (Buckingham et al. ed. 1994), glycosides, polysaccharides, 5% protein, 0.1% asparagin and vitamins B1, B2 and C have also been found (Hsu et al. 1986; Tierra 1988). Flowers and leaves tested negative for alkaloids in broad alkaloid screenings (CSIRO 1990; Fong et al. 1972).

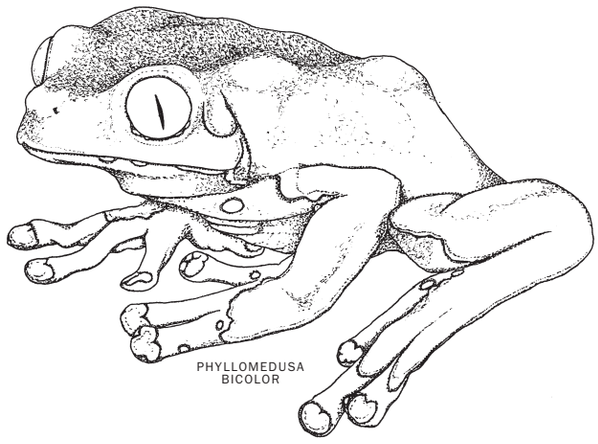
Phragmites australis is a robust, rhizomatous perennial grass to 6m high, with emergent aquatic creeping rhizomes and erect noded stems; lower nodes of stem bare, with complete or incomplete whorls of hairs. Leaves lanceolate, blade rolled in bud, flat, alternate, glabrous, to 3.5cm wide, midrib prominent; ligule a densely ciliate membranous rim with hairs c.1mm long, sometimes scattered with hairs to 10mm long on upper leaves. Spikelets numerous on filiform pedicels, forming a large, terminal, spreading ovoid panicle inflorescence, dense, often drooping, hairy, 15-30cm long, 5-20cm wide, green to purplish-brown and silvery-white at maturity; axils of branchlets with hairs to 7mm long; spikelets pedicellate, solitary, with 3-8 florets, lowest 1 or 2 male, others bisexual, disarticulating above glumes and at base of each lemma; rachilla with hairs c.12mm long; glumes lanceolate, unequal, mucronate or aristate, rounded on back, 3-5 nerved, thin, papery, glabrous, lower ones 3-5mm long, upper ones 6-8mm long; lemmas long-subulate, narrow, 3-5 nerved, papery, glabrous, male lemmas c.12mm long, bisexual lemmas acuminate, 10-16mm long, upper lemmas successively smaller; palea linear to oblong, 2-keeled, 3-4mm long; callus with hairs 10-12mm long. Seeds tiny, reddish. Fl. spring.

In wet places, especially at edges of ponds and streams, and in tid-

al waters; widespread (Harden ed. 1990-1993; Lamp & Collet 1989). Rhizomes harvested for consumption should be taken from the portions growing under mud, rather than those exposed to water (Cribb & Cribb 1981).

PHYLLOMEDUSA [with reference to Dendrobates, Phyllobates]

(Hylidae)



Phyllomedusa bicolor *Boddaert* – dow kiet!, sapo, sapo mono, monkey frog, giant monkey tree frog, giant leaf frog
Phyllomedusa rohdei *Mertens* – Rohde's leaf frog
Phyllomedusa spp. – leaf frogs, monkey frogs

Skin secretions of P. bicolor, known as 'sapo' [the generic Spanish name for toads – see **Bufo**], are used in hunting magic by the Matses, a subdivision of the Mayoruna of Peruvian/Brazilian Amazonia, and possibly also by the Amahuaca, who use an unidentified frog species. The Matses catch the frog by calling it, and keep it for 3 days, in which time the venom is periodically collected. To collect venom from the frog, its limbs are tied to support the animal from 4 small posts. The toes are massaged gently, and secreted venom is collected from the legs and sides with a piece of split bamboo. When covered, the stick is dried near a flame and stored for use (Daly et al. 1992a; Erspamer et al. 1993; Gorman 1993).

Before a hunting trip, sapo may be used to increase chances of a successful hunt. To apply it, the skin is burnt with a stick from the fire, and the skin scraped away; some sapo is scraped from the stick and mixed with saliva to form a paste, which is then rubbed into the wound. Several further applications are usually made, and it may be applied almost continuously for days in times of difficult hunting. Effects manifest within seconds – first, body temperature is raised greatly, accompanied by sweating and intense hypertension and tachycardia with sympathetic stimulation, purging and emesis, and loss of control of motor functions. One westerner [Peter Gorman] who had it applied to him on several occasions, also at this stage experienced the sensation of animal spirits passing through his body and expressing themselves through him, as he crawled growling on all fours. Another westerner [Piers Gibbon] who received applications of the venom did not note any of these particular mental effects. After this period, sympathetic symptoms subside, culminating in an exhausted but brief sleep, with some awareness of outside sounds still maintained. When full consciousness returns several hours later, all perceptive senses are greatly enhanced, particularly those of hearing and vision, and one feels 'god-like' and 'in tune with the environment', full of abundant stamina and agility, as well as diminished need for food. These latter effects reportedly last for several days afterwards, and are an invaluable aid in hunting in the jungle (Amato 1992; Gibbon pers. comm.; Gorman 1993, 1995).

On a similar note, skins of two unidentified frogs are used before hunting by the Patamona, Arecuna and Macusi; the skins are inserted into the nostrils and pulled through with twine, for the purpose of 'increasing sensory acuity'. This practice involves a small yellow frog with black spots, known as 'pa', and a small brown frog known as 'ambak' (Kennedy 1982; Morgan 1995). Indigenous inhabitants of some areas of Guyana also use the skin secretions and spawn of some frogs for the same effects, rubbing them into wounds, or the eyes, nose, mouth and ears (Furst 1976). The Yagua of Peru have been known to snuff the dried venom of an unidentified 'toad' or frog, mixed with **Calliandra** angustifolia seeds and 'pashaco' seeds [see *Endnotes*], to enter a visionary state and to increase the sense of smell for hunting (Bear & Vasquez 2000).

The sapo frog was for a while thought to be a species of Dendrobates or Phyllobates, whose secretions are known to be used as arrow poisons in the Amazon (Furst 1976); these frogs produce highly toxic alkaloids. Phyllobates spp. are known to produce batrachotoxins, highly potent steroidal alkaloids with neurotoxic activity [also found in some birds – see *Endnotes*]. P. terribilis contains high concentrations of batrachotoxins, as well as d-chimonanthine, l-calycanthine [see **Calycanthus**] and noranabasamine [a pyrrolidine alkaloid]. Dendrobates spp. produce pumiliotoxins [which are quinoline-derivatives] and other potent compounds (Daly & Witkop 1971; Daly et al. 1980, 1987; Witkop & Gossinger 1983). Known as 'poison arrow frogs', they are popular as expensive pets in the west, but seem to lose their toxicity when raised captively in terrariums (Daly et al. 1992b). Some species, such as Phyllobates terribilis, can maintain high [although still reduced] concentrations of alkaloids in captivity, even after 6 years. Frogs of this species raised totally in captivity, however, were "relatively nontoxic" (Daly et al. 1980). Frogs of the same species, but from different populations, have shown differences in the types of alkaloids present. It is believed that the biosynthesis of these alkaloids may be dependent on particular aspects of diet, environment, and genetics (Daly et al. 1992b).

P. bicolor venom yielded about 7% potent peptides of the caerulein, tachykinin, bradykinin, bombesin, tryptophyllin, sauvagine and opioid types – 3.2% phyllocaerulein [equivalent activity to caerulein – see *Endnotes*], 1.8% phyllokinin [hypotensive], 0.3% sauvagine [causes corticotropin release from pituitary, activating pituitary-adrenal axis; raises levels of β-*endorphin*, catecholamines and glucose; causes tachycardia and peripheral hypotension], 0.53% ala-deltorphin I [human activity uncertain], 2.2% phyllomedusin [hypotensive; stimulates gastric motility; antidipsogenic], 0.025-0.033% [lys7]-OH-*dermorphin*, similar amounts of [trp4,asn7]-OH-*dermorphin* [dermorphins are potent analgesics, due to selectivity for mu-opioid receptors; levels in venom samples studied are too low to contribute much effect] and adenoregulin [enhances binding at *adenosine* A1 receptors]. The pharmacology of the peculiar CNS effects reported has not been elucidated, but likely result from a complex interaction of the peptides. A single application of sapo may be about 10mg of dried venom; thus the usual 2-3 applications provide about 20-30mg of the drug (Daly et al. 1992a; Erspamer et al. 1986, 1993; Melchiorri & Negri 1996).

P. rohdei skin has yielded 0.001-0.0025% *bufotenine* and 0.0001-0.00015% leptodactyline (Roseghini et al. 1986), as well as large quantities of peptides similar to those found in P. bicolor [0.007-0.013% phyllokinin, 0.0015-0.0035% phyllomedusin, <0.0001% phyllocaerulein, <0.0005% sauvagine, 0.006-0.008% *dermorphins*]. Other species, such as P. burmeisteri, P. edentula, P. hypochondrialis, P. palliata, P. sauvagei and P. trinitatus have also yielded cocktails of peptides similar to those of P. bicolor, in varying relative proportions and total concentrations, though P. bicolor seems to bear particularly rich concentrations. Venom from P. lemur had similar activity to that from P. bicolor when injected into mice (Erspamer et al. 1986, 1993).

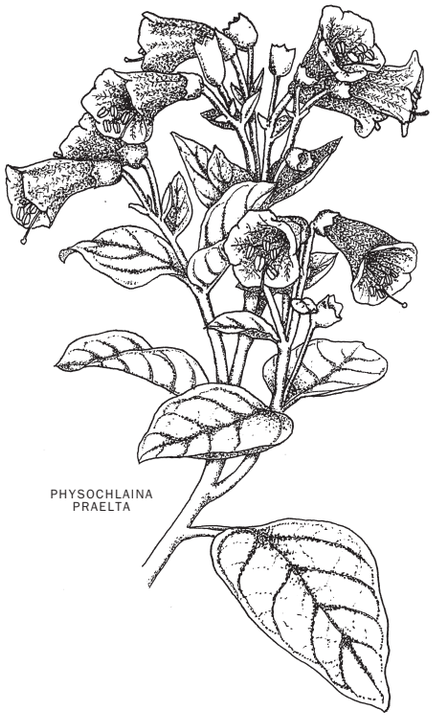
Phyllomedusa bicolor is a large frog, males 91-103mm, females 111-119mm; dark to bright green above, belly white to yellow-white to cream; white spots with dark frames found sparsely on lower lips, chest and front legs, more densely on flanks and hind legs, largely following the 'rim' where the dorsal green colour ends and light belly colour begins, and on each toe [there with a green patch inside the white and dark border]; fingers transparent brown to whitish-grey with large green adhesive discs, opposable first-fingers and toes, allowing a monkey-like grip; prominent gland from behind eye over the tympanum; eyes with dark grey iris, vertical black pupils; extremities whitish-grey, with green fingertips encircled with white and then black. They have a loud, barking call. Found in Amazon Basin, Brazil, Bolivia, Colombia, Peru, Suriname, French Guiana, Guyana and Venezuela (Lima et al. 2007; pers. obs. from photos).

Phyllomedusa spp. are nocturnal tree-dwellers. They are found on perches near streams and ponds in the breeding season, from which they may make their mating call, though P. bicolor sometimes will do this from the forest floor, where it can move only relatively slowly, due to its large toe pads. During the day, they [P. bicolor] retreat to tree perches ranging from 1.5-9m elevation. Good perches are remembered and re-used (De Oliveira 1996). In the wet season, Nov.-May, they mate on a leaf above the surface of a marsh or pond, using their hind legs to hold the edges of the leaf near its tip to form a funnel; into this, the female lays some eggs, which the male then fertilises, and the pair move a bit further along the leaf, repeating the process until the stem is reached. The leaf becomes a bag, held together by the gelatinous fluid of the eggs, and open at each end. When tadpoles hatch 8-10 days later, they fall through the lower opening into the water, where they develop, adhering to stones using their funnel-shaped mouths (Grzimek 1974; Lima et al. 2007).

Diploid and tetraploid species of Phyllomedusa are known to naturally hybridise (Haddad et al. 1994), with possible alterations in chemistry of skin secretions.

PHYSOCHLAINA

(Solanaceae)



Physochlaina alaica *Korotk. ex Kovalevsk*
Physochlaina dubia *Pascher*
Physochlaina infundibularis *Kuang* – hua han shen, hua shan seng
Physochlaina orientalis *(Bieb.) G. Don. fil.*
Physochlaina praelta *(Hook. f.) Miers* – bajar-bang, lang-thang, sholar, nandru, dandarwa

'Hua han shen', the dried root of P. infundibularis, is used in TCM to relax the bronchial muscles and depress the CNS (Huang 1993). In Kashmir, P. praelta leaves, which are said to be poisonous and to dilate the pupils, are applied externally to boils. Eating the leaves is said to "affect the head and the throat, and to cause the mouth to swell". A human accidental poisoning was recorded in 1867 – the man involved "suffered from its narcotic effects for 2-3 days" (Chopra et al. 1965; Kirtikar & Basu 1980).

P. alaica has yielded *hyoscyamine*, *hyoscine*, apo-*atropine*, 6-OH-*atropine*, 6-OH-*hyoscyamine* N-oxide and physochlaine (Buckingham et al. ed. 1994; Evans 1979; Mirzamatov et al. 1975).

P. dubia has yielded *hyoscyamine*, *hyoscine* and 6-OH-*hyoscyamine* (Buckingham et al. ed. 1994; Evans 1979).

P. infundibularis root yielded 0.26% alkaloids, consisting of *hyoscyamine* and *hyoscine*, as well as *scopoletin* and scoplin [I presume this was a printing error and should have been scopolin]; the plant has an LD50 of 43g/kg [i.p.] in mice (Huang 1993).

P. orientalis roots have yielded 0.718% alkaloids when the plant is flowering, consisting mostly [90%] of tropanes including *hyoscine*, *hyoscyamine* and two unidentified alkaloids; aerial parts have yielded *hyoscine* [0.239% in stems], *hyoscyamine*, and what may have been apo-*atropine* (Minina & Aduevskaya 1965); the plant has also yielded cuscohygrine and *chlorogenic acid* (Schermerhorn et al. ed. 1957-1974).

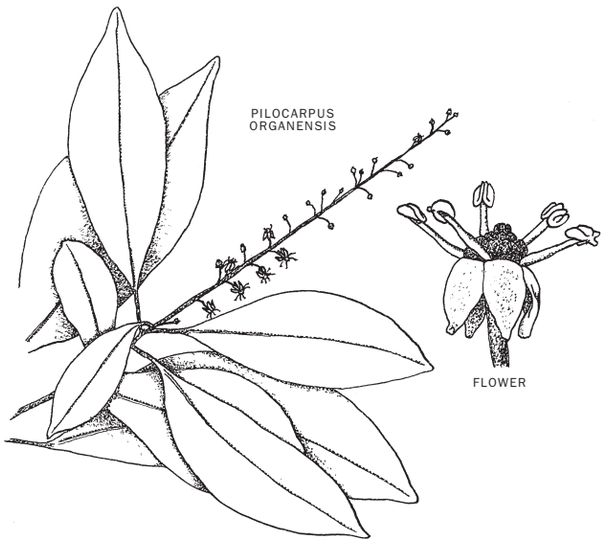
P. praelta has yielded 1.02% alkaloids from the leaves, of which 80% was *hyoscyamine*, with small amounts of *hyoscine*; roots yielded 0.64% alkaloids, mostly *hyoscyamine*, as well as 8% sucrose (Chopra et al. 1965).

Physochlaina praelta is an erect, nearly glabrous herb 60-120cm tall, corymbose upwards. Leaves subentire, 10-15 x 7.5cm, irregular, ovate-oblong, sinuate, base cuneate or cordate on the same branch; petiole 2.5-10cm. Inflorescence a terminal corymbose raceme 5-20cm diam., compound, lax, viscid pubescent; flowers all pedicelled; pedicels 0.6-3.8cm; calyx campanulate, unequal, 5-lobed, lobes lanceolate, 3mm, striate, in flower 8mm, in fruit 4.5 x 0.8cm; corolla elongate, 3.2cm x 5mm, tubular-funnel-shaped in majority of wild samples, sometimes shorter, in cultivated examples wider, subcampanulate, lobes 5, short, imbricate in bud; stamens attached at middle of tube; filaments filiform; stamens and style equalling the corolla, or up to 8mm longer, distinctly exserted in nearly all wild samples; anthers ovate, longitudinally dehiscent. Ovary 2-celled; style linear; stigma obscurely 2-lobed. Capsule 2-celled, 1.3cm diam., circumscissile above the middle; seeds many, compressed, 2mm diam., scrobiculate-reticulate; embryo peripheric (Kirtikar & Basu 1980).

South-western Xizang [China] to Nepal and Kashmir (Hawkes et al. ed. 1991).

PILOCARPUS

(Rutaceae)



Pilocarpus organensis *Occhioni et Rizzini* **(P. breviracemosus** *Cowan***; P. fluminensis** *Casar ex Engl.***; P. pauciflorus** *A. St.-Hil.***)** – pitaguara, do-branco

Although, strictly speaking, the above species is not a 'jaborandi', it is related to the group of plants who share that common name, and which are used medicinally in Brazil. These species are P. jaborandi, P. microphyllus, P. pinnatifolius, P. racemosus, P. spicatus and P. trachylopus. Jaborandi is often used as a powerful hair tonic, as it opens skin pores, presumably allowing the scalp to 'breathe'. A leaf decoction is taken internally as a stimulant, expectorant, sudorific and diuretic; it may also treat asthma, rheumatism, pleurisy, dropsy and diabetes, contracts the pupils and reduces intraocular pressure. In large doses, it is emetic (Bremness 1994; Henry 1939; Morton 1977; Usher 1974).

All of the above jaborandi types [except P. trachylopus] contain the toxic imidazole alkaloid pilocarpine and derivatives; this alkaloid is a muscarinic *acetylcholine*-receptor agonist (Jarv & Bartfai 1988; Kruk & Pycock 1983), exciting parasympathetic nerves. It can cause mental confusion, disturbed vision and increased gland secretions. It also accelerates heart rate [though weakening heart action], increases intestinal peristalsis and promotes uterine contraction. Larger doses can cause nausea, vomiting, diarrhoea, CNS paralysis, bronchial oedema, and can be fatal due to heart failure. It has been used in medicine applied to the conjunctiva of the eye to produce miosis (Henry 1939; Morton 1977).

P. organensis leaves yielded 1.06% alkaloids, of which *5-methoxy-DMT* was the major constituent [0.41%]; the remainder was not identified (Balsam & Voigtlander 1978). Although this is very promising, it has yet to be shown that this species doesn't also contain pilocarpine in toxic amounts. Care should be taken with identification, as P. organensis bears a superficial similarity to P. sanctum, which has flowers of a smaller diameter.

Pilocarpus organensis is a shrub or small tree 1-6m tall, trunk c.7cm diam., dead bark very thin, grey purplish-brown with minute elongate-reticulate cracks, falling off in minute chips; branchlets 2-4mm thick, greyish green-brown, shining when young, pubescent with hairs 0.05-0.1mm long, becoming glabrous with age; perules of terminal buds triangular, strigillose with yellow-tawny hairs c.0.3mm long. Leaves alternate or subopposite, sometimes crowded at apex of branchlets, simple or indistinctly 1-foliolate, blade elliptic to obovate, 5.5-16cm long (-30cm near ends of branchlets), 1.8-5.5cm wide (-9cm near ends of branchlets), long-attenuate or narrowly cuneate towards base, decurrent along petiole, apex obtuse or acuminate, tip retuse, emarginate, or entire, margin revolute, chartaceous or subcoriaceous, greyish-green, shiny, glabrous or pubescent with spreading hairs at base and midvein below, venation brochodidromous, midvein usually plane and longitudinally wrinkled above, principal veins prominulous; petiole semiterete, canaliculate towards base by erect wings, distally sometimes turgid-geniculate, 4-25(-40)mm long, 1mm thick, glabrous or pubescent with hairs 0.05-0.1mm, the wings formed by the decurrent base of the blade, up to 0.2-0.3mm broad. Inflorescence of subterminal racemes 1-2 per branch, erect, 5-40 x 1.5-2.5(-3)cm, in fruit to 45cm long, many-flowered, developing acri- and basi-petally; rachis

1-1.5mm thick, glabrous or puberulous with hairs 0.1mm long; bracts and bractlets depressedly triangular to 0.7mm long, subglabrous, bractlets 2-4, alternate or subopposite at variable height; pedicels 2.5-9(-11) x 0.5-1mm; flowers 7-9mm diam.; calyx rounded, thinly coriaceous, glabrous; petals cochlear to subvalvate, 3-3.9 x 1.7-2.4mm, inflexed at tip through 0.7mm, slightly carinate above, coriaceous, yellowish-green, shining underneath, glabrous but beneath in bud beset with hairs 0.05mm long; filaments truncate, flattened, 2-3 x 0.3-0.5mm, yellowish-green; anthers ovoid, heart-shaped or suborbicular, recurved, with a dorsal gland 0.2-0.5mm; disc 0.5-1mm high, 2-3mm diam., irregularly 10-plicate, glabrous to mostly strigose with yellowish-tawny, hyaline hairs 0.1-0.4mm; carpels 0.7-0.9mm high, protruding 0.3-0.6mm beyond disc, with internal glands. Ovule 1 per carpel; style at anthesis obsolete to 0.1mm long, 7mm thick, after anthesis to 0.2mm long; stigma subsessile, capitate, 0.2-0.5 x 0.5-0.7mm. Mericarps ellipsoidal or obovoid, dorso-apically rounded, blunt or rounded at very apex, with glands to 0.5mm, glabrous, but young and sterile ones are usually sparsely strigillose, dehiscent to 1/3-1/2 below tip; seed 1 per mericarp, ellipsoidal, 7.7-12 x 4.3-8.5 x 3.8-4mm, sometimes curved at apex, ventral axis straight, slightly keeled on back, testa externally flatly colliculate with angular interspaces 0.05-0.1mm. Fl. Mar.-Oct.

In forests and cerrado, 10-850m; Brazil [Bahia, Rio de Janeiro, Sao Paulo (rare), Parana and Santa Catarina] (Kaastra 1982).

PIMENTA

(Myrtaceae)

Pimenta dioica *(L.) Merr.* **(P. aromatica** *Kostel.***; P. officinalis** *Lindl.***; P. pimenta** *(L.) Cockerell***; P. pimenta** *(L.) H. Karst.***; P. vulgaris** *Lindl.***; P. vera** *Raf.***; Caryophyllus pimento** *Mill.***; Eugenia divaricata var. ovalis** *O. Berg.***; E. micrantha** *Bertol.***; E. pimenta** *(L.) DC.***; Myrtus dioica** *L.***; M. pimenta** *L.***; M. piperita** *Sessé et Moc.***; M. tabasco** *Schltdl. et Cham.***)** – pimento, allspice, Jamaica pepper

Pimenta racemosa *(Mill.) J.W. Moore* **(P. acris** *(Sw.) Kostel.***; P. acuminata** *Bello et Espin.***; P. pimento** *(O. Berg.) Griseb.***; Caryophyllus racemosus** *Mill.***; Myrcia pimentoides** *DC.***; Myrtus acris** *Sw.***; M. caryophyllata** *Jacq.***; M. caryophyllus** *Jacq.***; M. pimenta** *Ortega***)** – bay, bay rum tree, West Indian bay, bayberry, wild cinnamon

Still a popular spice today, P. dioica fruits were sometimes used by the Aztecs to flavour their 'cacao' beverages [see **Theobroma**]; in this combination especially, they are said to have aphrodisiac effects. In the Americas, the fruit and leaves of P. dioica are used to treat neuralgia and digestive problems, acting as a warming stimulant. The fruits are now commonly used as a cooking spice in sweet and savoury dishes (Bremness 1994; Rätsch 1990; Simonetti 1990). P. racemosa leaves yield an essential oil called 'bay oil' [not to be confused with the essential oil from **Laurus**], which is mixed with rum to make a hair and scalp tonic called 'Bay Rum', as well as lending its fragrance to commercial soaps, detergents, lotions and perfumes (Opdyke 1973b; Usher 1974).

P. dioica has stimulant, tonic, anaesthetic, analgesic, muscle relaxant, antioxidant, antiseptic, carminative and rubefacient properties. The fruit yields up to 4.5% essential oil, also found in the leaves, consisting of *eugenol* [60-80% in fruit oil; up to 96% in leaf oil], *methyleugenol*, cineol, caryophyllene, phellandrene and other compounds.

P. racemosa has stimulant, analgesic, anticonvulsant, antineuralgic, expectorant, antirheumatic, antiseptic and astringent properties. The fruit yields essential oil containing up to 56% *eugenol*, as well as *methyleugenol*, chavicol, linalool, limonene, myrcene, *pinene*, 1,8-cineole and terpinen-4-ol (Battaglia 1995; Lawless 1995); leaves contain 'bay oil', which consists largely [55-65%] of *eugenol* and chavicol, as well as *citral*, cineol, nerol, α-*pinene*, dipentene and myrcene (Opdyke 1973b).

Pimenta dioica is a fragrant tree to 15m tall; bark pale brown; young branchlets flattened, 4-angled. Leaves opposite, simple, entire, oblong to elliptical, blunt or rounded at apex, usually subemarginate, mostly 6-20cm long, thin-coriaceous, with +- pellucid glandular dots, aromatic when crushed, midrib impressed on upper surface, prominent beneath, nerves and veins only slightly prominent on both sides; stipules absent. Inflorescence a many-flowered compound panicle 4-12cm long, branching in threes, from upper axils; peduncles slender, 0.5-1.2mm thick; calyx tube obconic, adnate to ovary, to 1.5mm long, smooth, puberulous, lobes 4, thick, broadly rounded, c.1.5mm long, wide-spreading at anthesis, persistent on fruits; petals white, 1.5mm long, quickly deciduous; stamens many, originating around margin of thickened calyx-disc, usually inflexed in bud, free; anthers bilocular, opening by longitudinal slits. Ovary inferior, outside powdery-white or shortly silky, 2-celled, placentas axile or parietal; ovules 1(-2) in each cell, hanging from the apex of the inner angle; style simple, elongate; stigma small, capitate, peltate-convex, much thicker than style. Fruit a +- fleshy berry, crowned by calyx, +- globose, 4-6.5mm diam., black, pulpy, slightly sweet, almost tasteless; seeds (1-)2, hot to taste, with spiral embryo, cotyledons very short. Fl. Jan.-Aug.; fr. Aug.-Sep.

Common on wooded hillsides and upland pastures, to c.1050m; Mexico, Central America, Cuba, introduced in Puerto Rico, Barbados and other tropical countries (Adams 1972; Fawcett & Rendle 1926).

PIMPINELLA

(Umbelliferae/Apiaceae)

Pimpinella anisum *L.* **(Anisum vulgare** *Gaertn.***)** – aniseed, anise, anneys

Aniseed is a popular spice in cooking as well as in medicine. Generally used in Arabic, European or Indian foods, the seed may flavour bread, cakes and sauces, or marinate meats and fish. The seed is also used in the preparation of liquors such as 'Anisette', 'arrack', 'ouzo', 'Pernod' and 'Ricard'. Medicinally, a seed tea may be used to treat colic, flatulence, indigestion, nausea and bronchial complaints, due to the relaxant and expectorant actions of the seeds. In accord with this, the Cherokee use it to treat catarrh. The seed also has a mild oestrogenic effect. The essential oil of the fruit is used commercially to flavour toothpastes and mouthwashes, and to add scent to perfumes, soaps, detergents and lotions (Bremness 1994; Hamel & Chiltoskey 1975; Opdyke 1973a; Simonetti 1990).

Aniseed may apparently be burned in magical incenses to call forth spirits, or to drive away evil spirits. It is said that a pillow stuffed with aniseed will promote a nightmare-free sleep (Cunningham 1994). In tests on the psychoactive constituents of 'absinthe' [see **Artemisia**], P. anisum was found to cause drowsiness, and in a strong dose, "provokes drunkenness, trembling, epileptic convulsions, then like opium [see **Papaver**], muscle spasms, analgesia and sleep" (Conrad 1988). The essential oil from the fruits has shown anticonvulsant activity in mice, and motor impairment with greater doses (Pourgholamia et al. 1999).

P. anisum contains an essential oil concentrated in the seeds [2-3.5% essential oil]; this is mostly trans-*anethole* [75-90%], with 2.29% cis-*anethole*, isoanethole, *estragole*, 0.58% *safrole*, *myristicin*, *pinene*, camphene, linalool, acetoanisole, p-MeO-*acetophenone*, acetic aldehyde and anisic aldehyde [p-anisaldehyde; fungistatic]. Also found are coumarins, glycosides and a fixed oil. Some people experience a sensitisation reaction to the essential oil, due to the *anethole* content, but it is not normally irritating to the skin. The oral LD50 of the essential oil, in rats, is 1.82-2.74g/kg (Battaglia 1995; Harborne et al. 1969; Harborne & Baxter ed. 1993; Lawless 1995; Mabey et al. ed. 1990; Morton 1977; Opdyke 1973a; Simonetti 1990). Vietnamese P. anisum yielded 1-3% essential oil from leaves, and 10-13% from fruits; leaf oil contained 55-77% *anethole* and 0.07% cis-*anethole*, whilst fruit oil contained 80-95% *anethole* and 0.04% cis-*anethole* (Phiet et al. 1980).

Pimpinella anisum is a finely pubescent, strongly aromatic annual herb 10-50cm high; stems terete, striate, branched above. Lowest leaves reniform, incise-dentate or shallowly lobed; next leaves pinnate with 3-5 ovate or obovate dentate segments; upper cauline leaves 2-3-pinnate, with linear-lanceolate lobes and narrow, sheathing petioles. Flowers in terminal umbels; rays 7-15, sparsely puberulent; bracts absent or 1; bracteoles usually few, filiform; petals white, 5, apex inflexed; stamens 5. Fruit 3-5mm long, ovoid to oblong, shortly appressed-setose.

In well-drained, alkaline soil with plenty of sun; native to Syria, Egypt (Tutin et al. ed. 1964-1980).

PIPER 1

(Piperaceae)

Piper aduncum *L.* **(P. aduncifolium** *Trel.***; P. anguillaespicum** *Trel.***; P. angustifolium** *Lam.***; P. angustifolium** *Ruiz et Pav.***; P. celtidifolium** *Kunth***; P. cuatrecasasii** *Trel.***; P. cumbricola** *Trel.***; P. disparispicum** *Trel.***; P. elongatiifolium** *Trel.***; P. elongatum** *Vahl***; P. fatoanum** *DC.***; P. flavescens** *(DC.) Piper nigrum *L.* – black pepper, peppercorn vine, vine pepper, hu jiao, maricham, kalimirich, filfiluswud
Piper novae-hollandiae *Miq.* – native pepper [Australia]
Piper plagiophyllum *K. Sch. et Laut.* – kwawan dsaap
Piper regnellii *(Miq.) DC.* **(P. fulvescens** *DC.***; Artanthe regnellii** *Miq.***)**
Piper sarmentosum *Roxb.* **(P. albispicum** *DC.***; P. brevicaule** *DC.***; P. gymnostachyum** *DC.***; P. lolot** *DC.***; P. pierrei** *DC.***; P. saigonense** *DC.***; Chavica hainana** *DC.***; C. sarmentosa** *(Roxb.) Miq.***)** – sirih tanah, bakik, la lot, kado-kado, jia ju, qing ju
Piper schultesii *Yuncker ex Yuncker et Trelease* **(P. obtusilimbum** *DC.***)**
Piper wabagense – makum galua
Piper spp. [for **Piper methysticum** and **P. wichmannii**, see **Piper 2**]

Species of pepper [Piper spp. – not to be confused with **Capsicum**], widespread in tropical regions, have many and varied medicinal and culinary uses, yet some are used in psychoactive contexts and/or contain psychoactive compounds in their essential oils, as well as some interesting amides.

The common peppercorn vine [P. nigrum], from which white, green and black peppercorns are obtained (Bruneton 1995), has been used in Asia for at least 4,000 years, and was used by the Egyptians in embalming. Pliny reported that the spice was more expensive than gold, and would often be accepted as tax payment. The Romans kept huge storehouses of the dried fruits. Both Roman soldiers in Britain, and Buddhist monks in the Himalayas, used it as a stimulant and appetite suppressant for long journeys. It was used in mediaeval England as a poison antidote, and to prevent spread of infections (Lawless 1994). The Cherokee use it as a stimulant, astringent and food-seasoning (Hamel & Chiltoskey 1975), and it has been used as an aphrodisiac across Eurasia (Rätsch 1990).

In TCM, the dried fruit ['hu jiao' ('barbarian ginger')] is decocted in doses of 1.5-3g as a digestive, stomachic, carminative, eliminative and food poisoning antidote, also being noted as having anticonvulsant and sedative effects (Huang 1993; Reid 1995). In rural India, it is inhaled to treat fainting or hysteria (Lawless 1994). Along with P. longum, it is used in Tibetan and Nepalese medicine to treat nervous conditions (Clifford 1984; Ott 1993). Fruits of this latter species are used in India as a stimulant, aphrodisiac, carminative, vermifuge and emmenagogue (Nadkarni 1976). The stem and root ['piplamul'] are used in Indian medicine to treat bronchitis, stomach pains, palsy, flatulence and other disorders (Bisht 1963). In TCM, P. longum fruit spikes ['bi ba'] are used to dispel cold and relieve pain (Huang 1993). In some Ayurvedic preparations, P. nigrum and/or P. longum appear to increase the bioavailability of active constituents of the herbs with which they are combined (Bruneton 1995). Contemporary reports from western psychonauts indicate that P. nigrum is psychoactive (Weil 1969), and its essential oil is used by aromatherapists as an aphrodisiac, analgesic, antiseptic, nerve tonic and mental stimulant (Lawless 1994). In Indonesia, P. cubeb is taken as an aphrodisiac (Rätsch 1990). In India, fruit of P. aurantiacum is said to 'excite the memory'. In Unani medicine, fruit of P. chaba is snuffed to treat epilepsy and hysteria (Nadkarni 1976). In Nepal, the root is an ingredient of psychotropic 'bobkha' cakes [see Spatholobus parviflorus in *Endnotes*] (Müller-Ebeling et al. 2002).

P. betle is well-known for being the leaf in which the betel nut [see **Areca**] is wrapped for chewing, for which large quantities of the male plants are vegetatively cultivated in India. It is considered a milder stimulant than betel nut, and in Indian medicine is used as a carminative, stomachic, anthelmintic, tonic [to the brain, heart and liver], aphrodisiac, laxative, and appetite stimulant – in large doses, it is said to be inebriating. Leaf juice is used as eyedrops, and may treat coughs and catarrh, as well as showing antimutagenic, antitumorigenic (Balasubrahmanyam & Rawat 1990; Kirtikar & Basu 1980; Nadkarni 1976; Ott 1995a; Rawat et al. 1989; Watt & Breyer-Brandwijk 1962) and antioxidant effects (Jeng et al. 2002). Kirati shamans of Nepal use a plant called 'dupsi' [also 'dhupsi' or 'dutsi'] for shamanic travel, with one shaman reporting "You need not even smoke or eat the leaves, the smell alone puts you in a trance". 'Dhupi' is reportedly a Nepalese name for P. betle, but it is unclear whether this is the same species as the shamanic one just mentioned. The similar word 'dhup' refers to numerous incenses and the plants used to make them (Müller-Ebeling et al. 2002).

P. aduncum is used in Peru as a styptic and gonorrhoea treatment; it is stimulant, diuretic and astringent (Watt & Breyer-Brandwijk 1962). The leaves and fruits are used as an aphrodisiac, either decocted or mixed with cacao [see **Theobroma**] (Rätsch 1990). P. attenuatum roots are macerated in water or decocted in n. India as a diuretic, and the Mikir of India use it in worship ceremonies (Kirtikar & Basu 1980; Ott 1993; Usher 1974). In Mexico and other parts of Central America, P. auritum is used as a food seasoning, as well as treating urinary tract and gynaecological disorders. Crushed leaves are used to attract and stun fish in the dry season – the fish are then trapped and fed more of the leaf to pre-season them for cooking. The leaves are also used to wrap fish for steaming (Gupta, M.P. et al. 1985; Usher 1974; pers. obs.). Smoking them produces a "pleasant, mild buzz" (Rätsch 1999a). P. cryptodon is used by the Yanomamo of Amazonia as a tobacco substitute [see **Nicotiana**] (Ott 1993). P. interitum is used by the Kulina of Peru, who pulverise the dried leaves and roots to make a possibly-psychoactive snuff. Various unidentified Piper spp. are utilised in S. America. One unidentified species is used as an ayahuasca additive [see **Banisteriopsis**]. Another, used by the Tanimuka and Yukuna [known to them as 'he-djoo-roo' or 'ne-e-too', respectively], is made into a leaf tea which 'strengthens men'. Piper sp. 'do-pia' is used by Andoke shamans for 'mental blindness', to obtain 'clear thinking'. Piper sp. 'si-ta' leaf is smoked or chewed by the Andoke in shamanic practices. In e. Ecuador, the Canelo use a Piper sp. they call 'guayusa' [see **Ilex**] as a stimulant (Schultes & Raffauf 1990). The Karijona of n.w. Amazonia give leaves and stems of P. schultesii in water or 'chicha' [see *Methods of Ingestion*] to elderly people who "sit without talking all day" (Schultes 1993), presumably as a mental stimulant.

In n. Ghana, the Kusasi make an intoxicating snuff from P. guineense seeds, **Securidaca** longipedunculata root, Tinospora bakis root [see *Endnotes*], Fagara xanthoxyloides root [see *Endnotes*] and red pepper [see **Capsicum**]. Sometimes **Ipomoea** digitata root is also added. This snuff is used during shamanic initiation; the effects may last over an hour, during which time the initiate appears to be unconscious (De Smet 1998).

Stem internodes of an unidentified Piper sp. are used as pipes for smoking ritual tobacco in stages 7-9 of shamanic initiation amongst the Bimin-Kuskusmin of Papua New Guinea (Poole 1987). The Nkopo of PNG chew the leaves of P. gibbilimbum, P. plagiophyllum and P. wabagense as inebriants with betel nut (Schmid 1991). In Australia, P. novae-hollandiae has been chewed by indigenous people to treat sore gums; it has a strong numbing effect, and alcoholic extracts have shown activity against a type of lung cancer in mice (Cribb & Cribb 1981).

Most Piper spp. contain a very wide array of compounds, and to list them all for each of the species covered here would be excessive – hence, the listings below mainly present the information which may be of most interest.

P. aduncum has yielded *elemicin*, *dillapiole* [33% of leaf essential oil, 62% of spike essential oil], *myristicin*, *safrole*, *asaricin*, 2,6-dimethoxy-4-allylphenol, 1,3-dimethoxy-2-acetoxy-5-allylbenzene and α-humulene, as well as chalcones similar to those found in P. methysticum [see **Piper 2**] (Mundina et al. 2001; Parmar et al. 1997). As P. angustifolium, it has yielded 2.5% essential oil, containing *asarone*, *dillapiole*, *apiole*, *methyleugenol*, *camphor*, matico-camphor, cineol, *borneol* and other terpenes (Atal et al. 1975; Parmar et al. 1997).

P. amalago leaves have yielded *dopamine* and *GABA* (Durand et al. 1962).

P. arboricola has analgesic effects, and has yielded 3,4-dimethoxy-phenylpropionic acid and 3,4-dimethoxy-phenylpropylamine, both of which share this activity, though the former compound is more toxic, and less potent as an analgesic (Ho et al. 1981).

P. attenuatum has yielded guineensine and piperolactams A & D (Parmar et al. 1997).

P. auritum fresh leaf yielded 0.71% essential oil, of which c.70% was *safrole*, along with traces of *eugenol*, *myristicin*, *elemicin*, *camphor*, α-humulene and other compounds (Gupta, M.P. et al. 1985); the aporphine alkaloids cepharadione A & B were also found (Hänsel et al. 1975), as well

as *GABA* (Durand et al. 1962). As P. sanctum, the plant yielded kava-lactones [see **Piper 2**] – *methysticin*, 5-MeO-5,6-dehydromethysticin, (+)-(5S,6S)-5-acetoxy-4,6-dimethoxy-6E-styryl-5,6-dihydro-2H-pyran-2-one and (-)-(5S,6S)-5-OH-4,6-dimethoxy-6E-styryl-5,6-dihydro-2H-pyran-2-one; as well as the piperolides [cinnamylidone butenolides] piperolide, methylenedioxypiperolide, 7,8-epoxypiperolide and (-)-threo-(3Z)-5-(2,3-dihydroxy-1-MeO-3-phenylpropylidene)-4-MeO-2-(5H)-furanone (Parmar et al. 1997), and the aphorphine alkaloids cepharadione A and cepharadione B (Hänsel & Leuschke 1976).

P. betle dry leaf yields 0.62-2.4% essential oil. The dominant compound is usually *eugenol*, but this depends on the cultivar type – 'Bangla' [oil yield (w/w) 0.15-0.2%] has c.64% *eugenol*, 19% *eugenol* acetate and 5% isoeugenol; 'Desawari' [oil yield (w/w) 0.12%] has c.45% *safrole*, 20% *eugenol* and 6% *estragole*; 'Kapoori' [oil yield (w/w) 0.1%] has c.33% *eugenol*, 11% isoeugenol and 6% *safrole*; 'Sanchi' [oil yield (w/w) 0.16%] has c.23% *safrole* and 14% *eugenol*; and 'Meetha' [oil yield (w/w) 0.85%] has c.19% *anethole*, 19% *eugenol* and 8% *estragole*. P. betle also may yield *isosafrole*, *methyleugenol*, chavicol, hydroxychavicol, chavibetol, 1,8-cineole, carvacrol, cadinene, caryophyllene and many other terpenoids; as well as vitamins A & E (Atal et al. 1975; Balasubrahmanyam & Rawat 1990; Ott 1995; Parmar et al. 1997; Rastogi & Mehrotra ed. 1990-1993; Rawat et al. 1989; Schermerhorn et al. 1957-1974; Watt & Breyer-Brandwijk 1962). It also reportedly contains a mysterious alkaloid, 'arakene', which was claimed to have similar properties to *cocaine* (Nadkarni 1976).

P. brachystachyum has yielded *apiole* from its essential oil (Atal et al. 1975; Parmar et al. 1997).

P. callosum leaf [from Peruvian Amazon] essential oil was found to contain 35.9% *asaricin*, 20.2% *safrole*, 9.7% *methyleugenol* and 7.8% α-*asarone* (Van Genderen et al. 1999).

P. cubeba seed contains an antioxidant and antimicrobial essential oil with β-cubebene [18.9%], cubebol [13.3%], sabinene [9.6%], α-copaene [7.4%], β-caryophyllene [5.3%] and many other constituents in lesser amounts; oleoresins with the same properties are also found, containing mostly cubebol (Singh et al. 2008). The lignans dihydrocubebin, clusin, dihydroclusin, yatein and hinokinin inhibited cytochrome P450 3A4 enzymes (Usia et al. 2005).

P. guineense has yielded *elemicin*, isoelemicin, *myristicin*, *safrole*, *dillapiole*, *eugenol*, *methyleugenol* and *asaricin* (Parmar et al. 1997).

P. lanceaefolium leaves [from Cuba, harv. Mar.] yielded 0.6-1.2% essential oil, consisting of 24.4% *elemicin*, 11.7% *apiole*, 0.2% *asaricin*, 20.6% β-caryophyllene, 12.5% germacrene D, 4.4% β-*pinene*, 3.5% α-*pinene*, 3.2% α-copaene and small amounts of many other compounds; spikes yielded 0.7% essential oil, consisting of 16.4% *elemicin*, 9.8% *apiole*, 0.2% *asaricin*, 15.8% β-*pinene*, 13.7% α-*pinene*, 6.9% γ-terpinene, 2.4% α-terpinene, 3% terpinolene, 5.1% β-caryophyllene, 3.7% 6-E-nerolidol, 3.2% germacrene D and smaller amounts of many other compounds. There is much variation in this poorly-known species, and essential oils from some leaf samples also contained *dillapiole* as a major constituent (Mundina et al. 2001).

P. lenticellosum has yielded *elemicin*, *methyleugenol* and *asaricin* (Parmar et al. 1997).

P. longum fruit has yielded 0.19-6% piperine, piperidine, and 0.7-0.9% essential oil containing phellandrene, caryophyllene, dipentene, p-MeO-*acetophenone*, zingiberine and other compounds (Atal et al. 1975; Bisht 1963; Handa et al. 1964; Keys 1976; Nadkarni 1976; Parmar et al. 1997). Piperine [which is a major alkaloidal constituent in P. longum and P. nigrum fruits] is 50 times more potent as a releaser of substance P than capsaicin [see **Capsicum**], and also inhibits cytochrome P450 (Koul et al. 2000; Nemeth et al. 1999) and MAO [both MAO-A and MAO-B in mouse brain] (Lee et al. 2008); piperine acts as a CNS-depressant and anticonvulsant in rats (Bruneton 1995). Methylpiperate and guineensine from the plant also inhibit MAO [the former more strongly with MAO-B]. Piperlonguminine has also been found (Lee et al. 2008). The roots have yielded piplartine [piperlongumine], which is effective in relieving asthma and chronic bronchitis (Buckingham et al. ed. 1994).

P. marginatum root has yielded [probably w/w] 0.0006% *apiole*, *croweacin*, 0.0002% isoasarone, 0.0006% *exalatacin*, 0.001% marginatine [3,4-methylenedioxy-1-(2E-octenyl)-benzene] and 0.0005% pipermargine [1-(1E-propenyl)-2,4,6-trimethoxybenzene] (De Oliveira Santos et al. 1997, 1998); aerial parts yielded 0.116% *safrole*, *dillapiole*, *anethole*, *myristicin*, *elemicin*, isoelemicin, *estragole*, *methyleugenol*, *methylisoeugenol*, 0.066% piperonal, 0.133% 3,4-methylenedioxypropiophenone, 0.055% 2-OH-4,5-methylenedioxypropiophenone, 0.0133% 2-MeO-4,5-methylenedioxypropiophenone, stearic acid and α-humulene (De Diaz & Gottlieb 1979; Parmar et al. 1997).

P. nigrum fruit essential oil [c.0.8%] has yielded *methyleugenol*, *eugenol*, *myristicin*, *safrole*, 0.22-3.59% α-*thujone*, larger amounts of *pinene*, and caryophyllene, α-phellandrene, camphene, terpinene, limonene, myricine, sabinene, piperonal, citronellol, α-humulene and other trace components (Atal et al. 1975; Battaglia 1995; Huang 1993; Parmar et al. 1997); the fruit has also yielded 5-9% piperine, 5% piperidine, piperamine, N-trans-feruloyl-piperidine, chavicine, feruperine and dihydroferuperine (Huang 1993; Inatani et al. 1981; Keys 1976; Nadkarni 1976). The whole plant tested positive for HCN (Watt & Breyer-Brandwijk 1962).

P. novae-hollandiae has yielded *dillapiole* and alkaloids [piperine, piperlonguminine, Δ-dihydropiperine, N-isobutyl-2,4-decadienamide, chavicine, N-isobutyl-2,4-octadienamide, 3,4-methylenedioxy-cinnamoylpiperidide and fagaramide] (CSIRO 1990). Stem and bark harvested in April from Mt. Glorious, Queensland [Australia] tested positive for alkaloids; bark gave weaker positive results. Leaf from Rockhampton, Qld. [harv. Jan.] gave the strongest positive results (Webb 1949).

P. regnellii roots yielded 0.048% *apiole*, 0.05% *dillapiole*, 0.024% *myristicin* and 10 different neolignans (Benevides et al. 1999).

P. sarmentosum leaves have yielded 0.078% α-*asarone*, 0.05% γ-*asarone*, 0.017% *asaricin* and 0.004% *exalatacin*; α-*asarone* has also been found in the fruits (Masuda et al. 1991).

Piper betle is a climbing shrub; stems semi-woody, climbing by many short adventitious rootlets, very stout, much thickened at nodes; young parts glabrous. Leaves large, 15-20cm, broadly ovate, slightly cordate and often a little unequal at base, apex shortly acuminate, acute, entire but margin often undulate, usually 7-nerved, glabrous, thick, bright green and shining on both sides; petiole 2-2.5cm, stout. Flowers dioecious (very rarely hermaphrodite), each in the axil of a bract; spikes dense, cylindrical; female 2.5-5cm, pendulous; bracts triangular-rotundate, peltate, yellow; rachis pilose; stamens 2-4 (rarely more); filaments short; anthers 2-celled, cells distinct. Ovary 1-celled; ovule solitary, erect; style short; stigmas 5-6, spreading stellately. Fruit sparingly produced, quite immersed in the fleshy spike, small ovoid or globose 1-seeded berry; seeds usually globose, testa thin.

Cultivated in hotter and damper parts of India and Ceylon, as well as Malay Islands (Kirtikar & Basu 1980).

Requires tropical conditions, with cool shade, high humidity and moist soil; very frost-sensitive. Enjoys loamy, porous soil, pH 7-7.5. Propagate from stem cuttings from the middle of the vine, pieces 6-8 nodes long. Females are often not cultivated as they are more susceptible to disease and adverse conditions. Male plants are often grown in thatch huts with vertical poles inside for vine-support (Balasubrahmanyam & Rawat 1990).

'Peppercorns' from P. nigrum are harvested at different stages of maturity, depending on the type of pepper to be produced. The berries turn from green to red as they mature. For 'green pepper', the fresh berries are harvested when green, and are usually stored in an acidic solution such as vinegar. For 'black pepper', the berries are harvested as soon as they turn red, then dried and separated from their stalks. For 'white pepper', the berries are collected when fully mature; they are soaked in water for a few days to aid in removing the pericarp and outer layers of the mesocarp, before drying the inner portion of the fruit (Bruneton 1995). 'Red peppercorns' are from a totally unrelated plant, Schinus molle (Simonetti 1990).

PIPER 2

(Piperaceae)

Piper methysticum *Forster f.* **var. methysticum** – kava, kava kava, kawa, kawa kawa, awa, pu'awa, yaona, yaqona, yangona, wati, ava pepper

Piper wichmannii *DC.* **(P. arbuscula** *Trel.***; P. erectum** *DC.***; P. methysticum** *Forst. f.* **var. wichmannii** *(DC.) Lebot stat. nov.***; P. schlechteri** *DC.***)** – gisam makum

Kava, a name used to define both a plant [P. methysticum var. methysticum, a sterile cultivar] and the inebriating drink made from its roots, is a very important ceremonial herb across much of Oceania, including w. Polynesia, New Caledonia, Solomon Isl., Hawaii, Fiji, Samoa, Papua New Guinea and Melanesia. It may be consumed for a great variety of reasons – to greet visiting dignitaries, before and after undertaking important work, to settle arguments, celebration of important events etc. A chief is expected to present a visiting chief with a piece of dried kava root. Kava is also used medicinally – in Hawaii, it is considered a nerve tonic, antifatigue agent and relaxant, and it may be used to treat asthma, rheumatism, obesity and congested urinary tract. The leaf is used as a poultice for headaches or to induce sweating. Many Pacific Islanders use it as a remedy against venereal diseases, especially gonorrhoea, and it has also been used to treat stings and inflammations. In Papua New Guinea, women drink freshly masticated kava as an anaesthetic during tattooing. Leaves and stems are also sometimes chewed in PNG as an inebriant. Kava also has some more sinister historical uses. Fijian and Hawaiian sorcerers have used it in enacting harmful magic against others. Usually, however, Hawaiian shamans ['kahuna'] used the plant in a more healing context; many other 'priests' amongst Pacific Island groups drank it to achieve a trance state, and receive ancestral inspiration. Shamans in Vanuatu ['kleva'] drink it for divination.

The kava ceremony was said to have been brought to humanity by Tagaloa Ui, the first Samoan high chief, who was the miscarried child of the union between a mortal girl called Ui, and the sun; the dead foetus was revived and nurtured by a hermit crab, a plover and a shrike. There

are, however many different legends recounting the origins of kava (Cox & O'Rourke 1987; Gatty 1956; Holmes 1967; Lebot et al. 1992; Ott 1993; Paijmans ed. 1976; Singh & Blumenthal 1997).

The root mass, once harvested [often along with the lower portions of the stems] is scraped clean and broken up into smaller pieces. The root used to be largely chewed [either by young girls or boys, depending on the culture] as part of the preparation ['Tongan method']. Chewers were selected for strong teeth and jaws, clean mouths and freedom from ailments. Very little saliva ends up in the resultant brew, but it served to emulsify the active resins from the root into the beverage. Today, the root is usually pounded or grated in a mortar ['Fijian method'], due to sanitation-related pressures from missionaries and government groups; this method also results in a less potent beverage. In either case, the ground kava is kneaded in a special bowl with water, and strained until the drink is clear of root fibres, during which time the chief of ceremonies may sing songs relating to the origins of kava. The participants are seated in a circle or in rows facing each other, and a respectful mood prevails. First, a cup of kava may be offered as a libation to the gods by pouring it on the ground, and then all participants are served one by one, beginning with the chief guest or most important person present. Being served last, however, is considered no less important than being served first. The kava is served in a half-coconut containing c.100mls of the drink – it is offered to each person by name and must be received with thanks in both hands and drunk in one slug, though those who do not partake may raise the cup in salutation and return it to the bearer still full. If it is only partly consumed, the cup must be emptied before being returned. When all have been served, the end of the ceremony is announced, the announcer is thanked and a meal is sometimes commenced. There are, of course, regional variations on the details of the kava ceremonies. Some groups, such as on Tongariki, consume it with much less ritual, as more of a recreational drug (Cox & O'Rourke 1987; Gajdusek 1967; Gatty 1956; Holmes 1967; Marshall 1987; Singh & Blumenthal 1997).

The Melanesian P. wichmannii is the fertile wild ancestor to P. methysticum var. methysticum, and is not known to be consumed as kava, due to its less-desirable effects [believed to be due to the ratios of active constituents present, compared to kava – see below]. The plant is used in New Guinea to counter magic. Also there, the Nkopo of the Madang and Morobe provinces use it to achieve 'gisam', a state of well-being and harmony with nature (Lebot & Levesque 1996; Schmid 1991; Singh & Blumenthal 1997).

The use of kava as an alcohol-substitute has existed in parts of northern Australia since at least 1982, amongst some indigenous Australian groups [see *Questions and Answers*]. It is worth noting that since the recent introduction of legal restrictions on the importation and sale of kava in Australia, herbal-pharmaceutical supplement companies have virtually monopolised the market, and caused a world-wide shortage of kava, as well as the associated increase in price. In Australia, kava is a Schedule 4 prohibited import, though people over 18yrs of age may bring in personally up to 2kg of root. The sale and commercial importation of kava now requires a government-issued license (Australian Bureau of Criminal Intelligence 2000).

The Hawaiian strain known as 'black kava' is said to be very potent; its leaves are claimed to be as potent as roots from strains of ordinary strength! 'Red kava' ['lehua kava'] is said to be even more potent still (Ott 1993). 'White' varieties are generally considered the best, though, but this field is very complex and cannot be generalised so easily. There are more than 72 cultivated varieties of P. methysticum recorded, many of which have not been chemically analysed (Singh & Blumenthal 1997).

Kava-lactones [kava-pyrones], the active agents in kava [see below], are not soluble in cold water, though they form a limited suspension in hot water; they are soluble in alcohol, fats and oils. Today in the west, the root is often prepared as follows – 14-28g dried kava is blended cold or heated with 300ml water [preferably coconut milk], 2 tabs olive oil and 1 tab lecithin. After thorough blending, this should be strained, and consumed at will. Effects are usually felt within 30 minutes, and last several hours. The effects are usually quite mild the first few times one tries kava, and are best appreciated in a dimly-lit, quiet environment. The bitter, soapy drink is astringent and numbs the mouth. Small amounts are gently euphoric; larger amounts induce pleasant relaxation, feelings of sociability, mood elevation, and sedation of the lower limbs. It is similar in some ways to alcohol inebriation, but without mental clouding or incoordination, and is said to give pleasant dreams [though others say it promotes a dreamless sleep]. It stimulates, then slows respiration, reduces cardiac rhythm, and can dilate the pupils. Higher doses still can induce a mildly psychedelic state of delirium. However, with all kava, the exact nature of the effects depends on the proportions of active chemicals in each strain. Daily high-dose use for several months to 1 year or more is known to produce negative physical side-effects such as dry, scaly skin lesions, reduced appetite for food and sex, sleep disorders, stomach pains, bloodshot sticky eyes and extreme lethargy (Baill pers. comm.; Gottlieb 1992; Lebot et al. 1992; Meyer 1967; Miller 1985; Pendell 1995; Singh & Blumenthal 1997). There are some cases of serious liver toxicity known; two women suffered acute necrotising hepatitis which resolved itself after kava consumption was ceased, and a teenage girl [taking normal doses for 3 months to treat anxiety] and a 50 year-old man [taking high doses for 2 months] suffered liver failure and required liver transplants (Campo et al. 2002).

P. methysticum root is c.80% water when fresh; dried root contains c.12% water, 43% starch [20% fibre, 32% sugars], 3.6% amino acids and 3.2% minerals [2.24% K, 0.37% Ca, 0.18% Mg, 0.11% Na, 0.15% Al, 0.11% Fe and 0.09% silica]. Kava contains a blend of resinous sesquiterpene-like compounds called kava-lactones or kava-pyrones. The dried root may yield c.3-20% of these compounds; 1-1.5g of the concentrated resin is considered a strong dose. There are several major kava-lactones – those being *kawain*, *yangonin*, *methysticin*, *7,8-dihydrokawain*, *dihydromethysticin* and *5,6-dehydrokawain* [desmethoxyyangonin; appears to have little effect]. Any given strain of kava may contain about 3 major kava-lactones [more than 70% of total], and others in traces; these variations give different effects from different cultivars. Large doses of the kava-lactones [except *yangonin* and *5,6-dehydrokawain*] can produce ataxia and paralysis without loss of consciousness. They appear to act synergistically, and also have antifungal and MAO-B inhibiting activity. Strains high in *dihydromethysticin* and *7,8-dihydrokawain* are the strongest, and have been known to cause nausea and 'drunkenness for 2 days'; strains high in *kawain* and low in *dihydromethysticin* and *7,8-dihydrokawain* produce what are said to be the most desirable effects. *Kawain* is also absorbed faster than the other kava-lactones. Kava also contains the minor kava-lactones 5,6-dehydromethysticin, 10-MeO-*yangonin*, 11-MeO-*yangonin*, 11-MeO-noryangonin, 11-OH-*yangonin*, 5,6,7,8-tetrahydroxyyangonin, 5,6-dihydroyangonin, OH-*kawain*, 11-OH-12-MeO-dihydrokawain, 7,8-dihydro-5-OH-kawain, 11,12-dimethoxydihydrokawain and 11-MeO-12-OH-dehydrokawain. Also found are the chalcones flavokavain A-C, dihydrokavain-5-ol, cinnamalaketone, N-cinnamoyl-pyrrolidine, 1-(O-MeO-cinnamoyl)pyrrolidine, cepharadione A, *choline* and transphytol. Kava-lactone content decreases from the root to the stump, with basal stems and leaves having even lower concentrations. Lebot et al. (1999) reported that the bark peelings of a Hawaiian cultivar yielded 10.7% kava-lactones; they did not specify whether this was from root bark or stem bark. The leaves of Hawaiian cultivars have yielded 0.4-5.8% kava-lactones, consisting of the 6 major kava-lactones in varying concentrations; *dihydromethysticin* and *7,8-dihydrokawain* were always the major components. Leaves have also yielded an alkaloid, pipermethysticin, which is found in traces in the roots; it is unstable and of unknown pharmacology. Fijian kava leaves have also yielded flavokavains A & B, and β-sitosterol (Buckley et al. 1967; He et al. 1997; Keller & Klohs 1963; Lebot et al. 1992; Lebot et al. 1999; Meyer 1967; Parmar et al. 1997; Pendell 1995; Singh & Blumenthal 1997; Uebelhack et al. 1998).

P. wichmannii root yielded c.8.4% kava-lactones, consisting of 31.84% *dihydromethysticin*, 19.49% *5,6-dehydrokawain*, 18.94% *7,8-dihydrokawain*, 16.95% *methysticin*, 7.28% *yangonin* and 5.19% *kawain* – though, as with the cultivar P. methysticum, different chemotypes have been observed, bearing differing proportions of these major kava-lactones (Lebot & Levesque 1996).

Piper methysticum is a shrub 1.5-3m tall; stems jointed, swollen at nodes. Leaves alternate, cordate, 13-30cm long, 10-23cm wide, palmately veined, principal veins 9-13, spreading from base except the 3 uppermost, +- pellucid-punctate, lower surface minutely puberulent on veins, margin entire; petioles 2-3cm long; stipules accrescent and usually persistent, at ultimate node and sometimes at some of the lower nodes, ultimate stipule forming a lanceoloid sheath enclosing the developing stem, 4.5-5.5cm long, 0.8-2.2cm wide. Plants dioecious; flowers unisexual, in solitary, leaf-opposed spikes, each subtended by a minute glabrous bract; mature spikes white, 3-9cm long including peduncle; peduncles up to 1.5cm long; stamens 2-4. Ovary 2-4(-5)-carpellate; stigmas as many as carpels, essentially terminal. Fruit drupaceous, rarely or not occurring. Female plants are very rare.

Thrives at 150-300m in cool, humid highlands, in stony ground or loose, rich, well-drained soil; native range unknown, widely cultivated in Pacific Islands (Wagner et al. 1990).

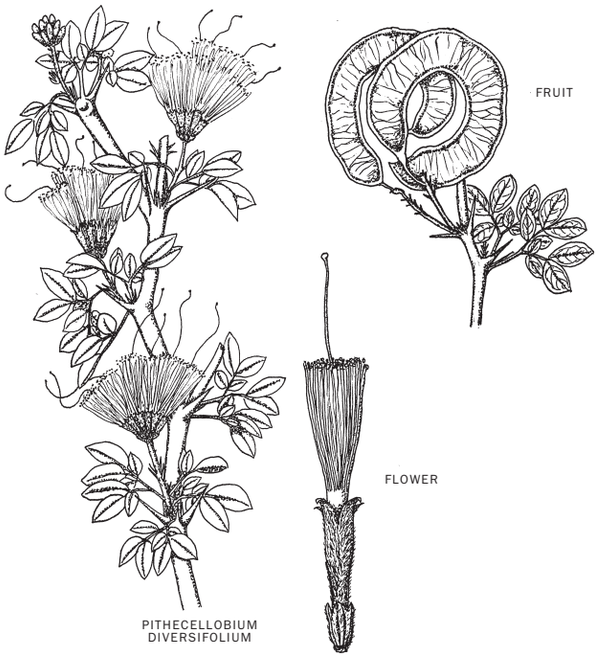
As mentioned earlier, P. methysticum is no longer considered to be a true species, but rather consists of sterile cultivars developed over time from variants or mutants of P. wichmannii (Lebot & Levesque 1996).

Cultivation is usually by cuttings of the firm wood of young branches [2 joints long if >2.5cm diam., 4 joints if less] cut diagonally between the nodes – usually 2 are planted together to produce a bigger plant. Stick cuttings in ground nearly diagonally to bury one node; grow in deep, friable, well-drained soil, rich in organic matter, pH 5.5-6.5. They must be protected from direct sunlight and wind – shade is required for the first 30 months. Requires 20-35°C temperatures, 70-100% relative humidity, an altitude under 400m, and over 2200mm annual precipitation [min. 1800mm at higher altitudes]. Cuttings are most susceptible to damage from lack of water in the first 6 months. The root is considered mature after c.3-5 years of growth, when it may extend to 60cm or more underground and be 5-8cm thick. The root mass and lower stems are dug up and their outer layer scraped off. A 3-year old plant may yield 10kg of fresh rootstock; drying reduces the weight to c.1/5 of original. One 4-year old plant from Pt. Vila, Vanuatu, grown in very sandy soil, had a rootstock

weighing 132kg fresh! Older roots are reputed to be more potent and more flavoursome, as are fresh roots; kava-lactone content is highest after 18 months, and remains +- stable, with little or no seasonal variation (Grubber 1973; Lebot et al. 1992; Singh & Blumenthal 1997). Kava-lactone content is apparently more reliant on chemotype and growing conditions [such as fertile, irrigated soil], than on the age of the plant, though smaller roots often have a higher content. Increased shade has been reported to decrease kava-lactone content (Lebot et al. 1999).

PITHECELLOBIUM

(Leguminosae/Mimosaceae)



Pithecellobium acacioides *Ducke* **(P. foliolosum** *Benth.***; Chloroleucon acacioides** *(Ducke) Barneb. et J.W. Grimes***)** – jurema branca

Pithecellobium arboreum *(L.) Urb.* **(P. filicifolium** *(Lam.) Benth.***; Acacia arborea** *(L.) Willd.***; Cojoba arborea** *(L.) Br. et R.***; Mimosa arborea** *L.***; M. filicifolia** *Lam.***)** – piule, coralillo

Pithecellobium contortum *(Graham) Mart.* **(Archidendron contortum** *(Mart.) I.C. Nielsen***; Inga contortum** *Graham***)**

Pithecellobium diversifolium *Benth.* **(Feuilleea diversifolia** *(Benth.) Kuntze***)** – jurema branca, brinco de saguim, espinheiro

Pithecellobium dumosum *Benth.* **(Chloroleucon dumosum** *(Benth.) G.P. Lewis***; Feuilleea dumosa** *(Benth.) Kuntze***)** – jurema branca

Pithecellobium grandiflorum *Sol. ex Benth.* **(P. tozerii** *F. Muell.***; Abarema grandiflora** *(Sol. ex Benth.) Kosterm.***; Archidendron grandiflorum** *(Sol. ex Benth.) I.C. Nielsen***; Feuilleea tozeri** *(F. Muell.) Kuntze***)** – laceflower tree, pink laceflower, fairy paint-brushes, gin's lips

Pithecellobium laetum *(Peopp.) Benth.* **(P. polycarpum** *Poepp.***; Abarema laeta** *(Benth.) Barneb. et J.W. Grimes***; Feuilleea laeta** *(Benth.) Kuntze***; Inga laeta** *(Benth.) Poepp.***; Klugiodendron laetum** *(Benth.) Br. et Killip***)** – remocaspi, pashaquillo, shimbillo

Pithecellobium tortum *Mart.* **(P. scalare** *Griseb.***; P. vincentis** *Benth.***; Chloroleucon tortum** *(Mart.) Pittier ex Barneb. et Grimes***; C. vincentis** *(Benth.) Br. et R.***; Feuilleea torta** *(Mart.) Kuntze***)** – jurema branca, Brazilian raintree

P. diversifolium roots and bark are used by a number of West African groups in Brazil as 'jurema branca', in a similar way to the true 'jurema' [**Mimosa** hostilis], presumably evoking a similar effect, or taking the role of a less active substitute (Lipp 1995; Rätsch 1992). P. acacioides, P. dumosum and P. tortum are also used in a similar way, as is the unrelated Vitex agnus-castus [see *Endnotes*; see also **Acacia** and **Mimosa**] (Ott 1997/1998, 1999). P. laetum is used in Peru as an ayahuasca additive [see **Banisteriopsis**] (Luna 1984). As 'remocaspi', it is consumed under a strict diet to receive esoteric wisdom. Death may result if the required diet is not kept. There may, however, be some confusion with **Aspidosperma** excelsum (Luna & Amaringo 1991). In Brazil, Pithecellobium spp. are also referred to as 'parica' [see **Anadenanthera** and **Virola**] (Schultes 1955), indicating possible past use as snuff ingredients.

The Mexican P. arboreum is known as 'piule' [see **Rhynchosia**], and is known to be narcotic (Schultes 1937b). In Malaya, P. contortum is reported to be 'stupefying' (Perry & Metzger 1980). P. bigeminum of n. India is used for its seeds, to treat diabetes, and its leaves, decocted as a hair tonic and fish poison. Wood of Pithecellobium spp. is sometimes used in construction and tanning leather, and the barks are often used to stupefy fish. Seeds of some species are used as coffee substitutes [see **Coffea**], and flowers yield a delicious honey (Allen & Allen 1981; Usher 1974).

Indigenous inhabitants of the Pennefather River area in Queensland, Australia, used P. grandiflorum as a kind of aphrodisiac. A preparation made from the inner bark, mixed with charcoal, was smeared on the front of the body [along with stripes of red clay down the outside of each leg] by men to excite and attract women, apparently due to the aroma and visual appearance thus produced (Cribb & Cribb 1981).

The chemistry of this genus is poorly known. Some species contain alkaloids such as pithecelobine (Allen & Allen 1981), which has since been found to be a mixture of several compounds (Buckingham et al. ed. 1994), and has been claimed to be toxic. Seeds of some species also contain the toxin djenkolic acid (Culvenor 1970; Krauss & Reinbothe 1973). However, P. lobatum has been shown to contain both pithecelobine and djenkolic acid, and in Malaysia its leaves, green pods and flowers are eaten as food (Allen & Allen 1981). There may be preparation methods involved which remove the toxins, so that these plant parts can be eaten safely, or perhaps the toxins are not orally active in humans.

P. acacioides [as P. foliolosum] leaf extracts weakly inhibited smooth and striated muscle contraction; this species was the weakest of those tested by Barros Viana et al. (1973), the others being P. multiflorum, P. polycephalum and P. saman (Barros Viana et al. 1973).

P. arboreum from Cuba [harv. Mar.] has yielded a triterpenoid glycoside, O(3)-(2-acetylamino-2-deoxy-β-D-glucopyranosyl)-oleanolic acid [0.06%], which was also found in P. cubense [0.15%; harv. same time and place] (Ripperger et al. 1981); seeds [as P. filicifolium] were shown to contain 4-OH-pipecolic acid, and smaller amounts of pipecolic acid itself (Krauss & Reinbothe 1973).

P. bigeminum has yielded pithecelobine (Allen & Allen 1981).

P. laetum has yielded lupeol, spinasterol and phytomitogenes (Rätsch 1992).

P. leptophyllum [aerial parts] from Mexico tested positive for alkaloids in a broad screening (Fong et al. 1972).

P. lobatum has yielded pithecelobine and djenkolic acid (Allen & Allen 1981).

Several species growing in Queensland, Australia were screened for alkaloids. P. grandiflorum from Tamborine [harv. Jun.] gave positive results from leaf and bark. P. hendersonii from Coolangatta [harv. Jan.] gave positive results from leaf. P. pruinosum from Rockhampton [harv. Jan.] gave weak positive results from leaf and mature seed. P. saman from Mossman [harv. Aug.] gave strong positive results from bark (Webb 1949). This latter species has yielded impure pithecelobine, and has since been renamed as Samanea saman (Allen & Allen 1981). Extracts of the leaves of Brazilian P. saman strongly inhibited smooth and striated muscle contractions [strongest of those tested], activities which appeared to correlate with alkaloid concentration (Barros Viana et al. 1973).

Pithecellobium diversifolium is a shrub to small tree; branchlets tortuose, pubescent, densely foliated; stipules spinescent. Leaves with scattered glands, bipinnate, 2-3 paired or in inferior pinnae with one pair of leaflets; pinnae 1-2-paired; leaflets obovate-oblong, both sides pubescent, upper leaflets mostly 12-19mm long, lower ones mostly smaller; petioles pubescent, smaller towards base. Flower heads terminal or axillary, solitary or clustered, globose, usually whitish, pedunculate; flowers hermaphrodite, pubescent; calyx campanulate, slightly 4-dentate; corolla slightly 4-lobed, tubular or infundibuliform, base united in tube; stamens numerous. Ovary glabrous, stipe elongate. Seed pods dehiscent, coiled, compressed, usually constricted between seeds, minutely tomentose, leathery; seeds thin, embedded in pulp, funicle filiform, aril slightly fleshy.

Province of Piauhy, Brazil (Bentham 1844).

PLUTEUS

(Agaricaceae/Plutaceae)

Pluteus atricapillus *(Secr.) Singer* **(P. atricapillus** *(Batsch) Fayod***; P. cervinus** *(Schaeffer) Kummer***)**

Pluteus atricapillus var. ealensis *Beeli* – abanda, losulu

Pluteus cyanopus *Quelet*

Pluteus glaucus *Singer*

Pluteus nigroviridis *Babos*

Pluteus salicinus *(Pers. ex Fr.) Kummer* **(P. petasatus** *(Fr.) Gillet***)**

Pluteus villosus *(Bull.) Decary et Romagn.* **(P. drepanophyllus** *(Schulz.) Sing.***; P. ephebeus** *(Fr. ex Fr.) Gillet***; P. lepiotoides** *Pears.***; P. murinus** *(Romagn.) Bres.***; P. pearsonii** *P.D. Orton***; P. robertii** *(Fr.) P. Karst***)**

P. atricapillus var. ealensis has been reported to be consumed by the Banza of Central Africa, sub-groups of whom also consume 'iboga' [see **Tabernanthe**]; the mushroom is apparently bitter and acrid-smelling

(Ott 1993).

P. atricapillus from Finland has yielded 0.004-0.005% *psilocybin* [only in 2 out of 5 specimens] (Ohenoja et al. 1987); Russian specimens were not found to contain any *psilocybin* (Gurevich 1995). It would seem to be at least possible that the African variant may contain *psilocybin*, though it has not been chemically analysed.

P. cubensis from Brazil yielded 0.05% *tryptamine*, though no *psilocybin*, *psilocin* or *serotonin* were found (Stijve & de Meijer 1993).

P. cyanopus has been reported to have *psilocybin*-like activity, but has not been analysed (Stamets 1996).

P. glaucus from Brazil has yielded 0.28% *psilocybin* and 0.12% *psilocin*; specimens of another Brazilian Pluteus sp., with a similarity to P. glaucus, yielded 0.15% *psilocybin* and 0.1% *psilocin* (Stijve & de Meijer 1993).

P. nigroviridis from Hungary [very rare] has yielded 0.035% *psilocybin* (Allen et al. 1992; Gartz 1996).

P. salicinus from Finland has yielded 0.21-0.3% *psilocybin* and 0-0.05% *psilocin* (Ohenoja et al. 1987); specimens from Sardinia [Italy] yielded 0.09% *psilocybin* and 0.03% *psilocin* (Ballero & Contu 1998); one analysis from Switzerland gave 0.05-0.25% *psilocybin*, and up to 0.008% *baeocystin* (Stijve & Kuyper 1985), though others [in Germany] have found much higher yields – 1.22-1.57% *psilocybin* in caps, 0.48-1.14% *psilocybin* in stems, 1.4-2.6% urea in caps, and traces to no urea in stems; small amounts of *baeocystin* and *tryptophan* were also found, in the caps only (Gartz 1987, 1996); another in Norway found 0.35% *psilocybin* and 0.011% *psilocin* (Christiansen et al. 1984). *Psilocybin* and *psilocin* have also been detected in samples from Czech Republic (Stríbrný et al. 2003) and Illinois, US. A variety of P. salicinus, P. salicinus var. achloes, does not bruise blue (Saupe 1981). As P. petasatus, this mushroom is often reported to be edible.

P. villosus has been reported to have *psilocybin*-like activity (Stamets 1996), though it was also stated by Singer to be inactive (Allen et al. 1992). Analysis found no *psilocybin*, but did detect unidentified *tryptamine*-derivatives (Toro 2004).

P. xylophilus var. tucumanensis from Brazil "contains several unidentified *tryptamine* derivatives", but no *psilocybin*, *psilocin* or *serotonin* (Stijve & de Meijer 1993).

Pluteus salicinus has a cap 2-5(-7)cm across, convex to broadly convex, then flattened and slightly umbonate, bluish- or greenish-grey, darker at centre, faintly striate when moist, surface smooth to finely scaly near centre. Stem 30-50(-100) x 2-6mm, white, sometimes becoming tinged with cap colour or bluish-green at base. Flesh white with greyish tinge. Gills free, not attached, pallid- to cream-white, then pink. Pleurocystidia fusiform to lageniform, with slightly thickened walls and with or without an apical crown of hooked ends, 58-90 x 10-22µ, apex 5-10µ thick; cheilocystidia pear-shaped to clavate, to cylindrical or slightly lageniform, 30-85 x 8-20µ. Spores pink, elliptic, (7-)8-9 x (5-)6-7µ, smooth. Fr. spring-autumn, frequent.

On dead or living deciduous wood [twigs or stumps; willow (Salix) or alder (Alnus)] in wet, rich habitats; United States, British Isles, northern Europe. Sometimes edible (Christiansen et al. 1984; Phillips 1981; Stamets 1996).

POLASKIA

(Cactaceae)

Polaskia chende *(Roland-Gosselin) Gibson et Horak* **(Cereus chende** *Roland-Gosselin*; **Heliabravoa chende** *(Roland-Gosselin) Backeberg*; **Lemaireocereus chende** *(Roland-Gosselin) Br. et R.*; **Myrtillocactus chende** *(Roland-Gosselin) P.V. Heath*) – chende, chente, chinoa

This Mexican cactus is sometimes used for its edible fruit (Trout & Friends 1999). It is of interest here due to its alkaloid content.

P. chende was found to contain up to 0.01% each of *mescaline*, *DMPEA* and 4-OH-3,5-dimethoxy-*phenethylamine* (Ma et al. 1986); an earlier alkaloid screening found specimens of this species to be rich in alkaloids (Fong et al. 1972).

Polaskia chende is a large, multi-branched cactus to 5-7m tall; trunk often short and indefinite when present. Branches slender, ascending or erect, ribs acute, 7-9; areoles c.1.5cm apart on older growth, sometimes closer together on younger growth; spines needle-shaped, brown to bright yellow, becoming grey with age, radial spines (2-)5, 1-2.5cm long, central spines 0-2, when present slightly longer than radials. Flowers rose-coloured, c.3-4(-5)cm long including ovary. Fruit deep red, very spiny with light-brown hairs, c.4cm diam.; seeds 1mm long.

Puebla and Oaxaca [1500-2200m], Mexico (Backeberg 1960; Britton & Rose 1963). Cultivate in a similar manner to **Stenocereus** (Trout & Friends 1999).

POLYGALA

(Polygalaceae)

Polygala senega *L.* – milkweed, milkwort, senega, seneka, snakeroot

Polygala sibirica *L.* **(P. heyneana** *Wall*) – yuan zhi, yuan chih, Japanese senega, himehagi, hsiao-ts'ao, chodat

Polygala tenuifolia *Willd.* **(P. sibirica var. angustifolia** *Ledeb.*; **P. sibirica var. tenuifolia** *(Willd.) Backer et Moore*) – yuan zhi, yuan chih, yuan chih shu, hsiao-ts'ao, chodat

The roots of these herbs are esteemed medicinally, and have many uses. P. senega is used by the Cherokee as a sudorific, diuretic, emmenagogue, expectorant and cathartic; it is taken for colds, pleurisy, rheumatism and inflammations (Hamel & Chiltoskey 1975). P. sibirica and P. tenuifolia have been used by Taoists as brain tonics, to improve memory and mental powers. In TCM, the root is considered warm, bitter and pungent, with an affinity for the lungs, kidney and heart. It has virtuous properties – known to be tonic, analgesic, antibacterial, uterotonic, expectorant [the root bark more so than the core], sedative and tranquillising, as well as nourishing the semen, improving hearing and vision, promoting muscle and bone growth, and clarifying mental faculties. The dried root of 'yuan zhi' is usually given in decoction in doses of 1.5-9g [or 1 tablespoon], twice a day for several weeks. It has shown synergy with barbiturates (Bone 1996; Gottlieb 1992; Hsu et al. 1986; Huang 1993; Reid 1995). At Mt. Hagen, Papua New Guinea, flowers of P. paniculata are eaten by women to treat infertility (Stopp 1963).

An unidentified plant believed to be a Polygala sp., known as 'bolao ba maqekha', has been referred to as "the charm of the witch-doctors" amongst the Basuto, who add it to a compound herbal drug given to those suffering from hysteria [see *Endnotes*, **Galium**] (Laydevant 1932). In southern Africa, the Suto use P. amatymbica as a 'cattle medicine', and it is known to have stimulant effects (Watt & Breyer-Brandwijk 1932). In Brazil, P. klotzschii has caused fatal intoxications in cattle [fatal dose 1kg/100kg], with pre-death symptoms including strong disequilibrium, laboured breathing and liquid diarrhoea (Pott & Alfonso 2000).

P. senega has yielded 5-10% saponins – senegenin, presenegenin, senegins II, III & IV, tenuifolin, onjisaponin B, 1,5-anhydroglucitol and 2-β,3-β,27-trihydroxyolean-12-ene-23,28-dicarboxylic acid [antiinflammatory]; as well as polygalic acid and methyl salicylate [analgesic] (Bruneton 1995; Buckingham et al. ed. 1994; Farnsworth & Cordell 1976).

P. sibirica and P. tenuifolia have similar chemistry, and are used in the same way. The active principles appear to be the triterpenoid saponins [c.0.7-4% of root], such as tenuifolin [prosenegenin], senegenin, tenuidine, polygalitol, onjisaponins A-G, and 1,5-anhydroglucitol; onjixanthones I & II, 6,8-dihydroxy-1,2,4-trimethoxyxanthone, 1,7-dimethoxy-2,3-methylenedioxyxanthone, 6-OH-1,7-dimethoxyxanthone, 3-OH-1,2,7-trimethoxyxanthone and 1,2,3,6,8-pentahydroxyxanthone are also found. Tenuigenin A1 & B1, as well as senegenin, are products of hydrolysis (Bone 1996; Buckingham et al. ed. 1994; Hsu et al. 1986; Huang 1993; Sakuma & Shoji 1981). P. tenuifolia has also yielded *norharman*, *harman*, 9-formyl-*harman*, 1-carbomethoxy-β-carboline, 1-carboethoxy-β-carboline and 1-carbobutoxy-β-carboline, from unspecified parts (Shulgin & Shulgin 1997). An extract caused 40% inhibition of AChE in rat brain extracts (Park et al. 1996).

Polygala sibirica is a many-stemmed herb, stems slender, 7.5-45cm long and hairy. Leaves alternate, rarely opposite or verticillate, round to elliptic, lanceolate and linear, 1.3-5cm long, shining margins often recurved. Flowers in racemes 2.5-7.5cm long, arising from axils of leaves or outside axils, with few or many flowers; flowers blue, hermaphrodite, 3-bracteate; sepals 5; outer sepals short or long, blunt or pointed, oblong-ovate to lanceolate; 2 inner sepals petal-like, obliquely oblong or inversely ovate, blunt or pointed, rarely long-pointed; petals 3, united at base with staminal sheath, the lower one keel-shaped and crested, crest usually large; stamens 8; filaments united for their lower half into a split sheath; anthers opening by pores. Ovary 2-celled; ovule 1 in each cell, pendulous. Fruit a capsule, 2-celled, loculicidal, smooth, broadly winged, 2-seeded; seeds hairy.

Temperate and subtropical Indian Himalaya, 300-1800m, in Sikkim 2400m, from n.w. frontier and the Punjab to Bhutan, Khasia Hills, 1200-1800m, w. Ghats from the Nilgiris to Tinnevelley, mostly above 1800m; also in China, Japan, Siberia (Kirtikar & Basu 1980; Steward 1958).

PROSOPIS

(Leguminosae/Mimosaceae)

Prosopis africana *(Guill. et Perr.) Taub.* **(P. lanceolata** *Benth.*; **P. oblonga** *Benth.*; **Coulteria africana** *Guill. et Perr.*) – ironwood, tentiera, kembo, ukpehe

Prosopis alba *Griseb.* **(P. atacamensis** *Phil.*; **P. siliquastrum var. longisiliqua** *Phil.*) – algarrobo blanco

Prosopis alpataco *Phil.* **(P. alba fo. fruticosa** *(Hauman) Monticelli***; P. juliflora fo. fruticosa** *Hauman***; P. stenoloba** *Phil.***)**
Prosopis juliflora *(Sw.) DC.* **(P. bracteolata** *DC.***; P. chilensis** *(Molina) Stuntz***; P. cumanensis** *(Humb. et Bonpl. ex Willd.) Kunth***; P. domingensis** *DC.***; P. glandulosa** *Torr.***; P. vidaliana** *Naves ex Villar***; Acacia cumanensis** *Humb. et Bonpl. ex Willd.***; A. juliflora** *(Sw.) Raf.***; N. occidentalis** *Br. et R.***; N. pallescens** *Br. et R.***)** – mizquitl, mesquite, honey mesquite, bayahond
Prosopis nigra *(Griseb.) Hieron.* **(P. algarobilla var. nigra** *Griseb.***; P. dulcis var. australis** *Benth.***)** – algarrobillo, algarrobo amarillo, algarrobo negro
Prosopis ruscifolia *Griseb.*
Prosopis sericantha *Gillies ex Hook.*
Prosopis spp. – mesquite, algarroba

Native to the Americas, 'mesquites' have spread over the continents via human introduction, due to their ability to give shade in dry, hot areas, to revitalise near-deserts, and to provide stock fodder in the form of the seed pods (Allen & Allen 1981; Parsons & Cuthbertson 1992; Simpson ed. 1977). The strong wood of many species is valued for building material – wood of P. africana is called 'ironwood', and is hard enough to blunt an axe. Sumerian records from pre-biblical times refer to an Iraqi species, P. stephaniana, as 'eri-tilla' or 'plant of the city of life' (Allen & Allen 1981). P. juliflora, known to the Aztecs as 'mizquitl', was considered a healing plant, and the wood has been used to fuel magical fires. Its pods, rich in sugars, are used to brew alcoholic beverages [such as 'pulqué' and 'chicha'] in Central America [see *Methods of Ingestion*]. Also available in some of these areas are a refreshing drink called 'mesquitatole' or 'pindle', an alcoholic beverage 'vino mesquite', and cakes called 'mesquitamales' (Burkill 1985-1997; Cunningham 1994; Rätsch 1998). In Haiti, P. juliflora has been reported as an ingredient of 'antidote' potions in the zombi phenomenon [see *Methods of Ingestion*] (Davis 1988a).

In n.w. Argentina, seeds of a Prosopis sp. have been found [along with **Anadenanthera** seeds, and puma-bone smoking pipes, the residue from which still contained *DMT*] in an archaeological site dating back some 4,000 years (Torres & Repke 1996).

In some parts of tropical Africa, leaves of P. africana are macerated and ingested as an aphrodisiac and male fertility tonic (Allen & Allen 1981); the wood is also said to be soporific (Watt 1967), and is used in magical practices – to some n. Nigerians, the plant is considered 'tabu'. The pods and seeds have also been used as a fish poison. In Mali, the macerated leaf of a mistletoe [see *Endnotes*] growing parasitically on P. africana is taken as an aphrodisiac and male sexual tonic (Burkill 1985-1997). Many mesquites also may yield quality honeys to bees [Apis spp. – see *Endnotes*] (Allen & Allen 1981).

Prosopis spp. are an excellent source of flavonoids [too numerous to be listed in full], monosaccharides and tannins, and some also contain indole and *phenethylamine* alkaloids. Most found at this point are simple derivatives of minor interest, yet with further searching in this genus alkaloids such as *DMT* may perhaps one day be detected.

P. africana leaves have yielded 3.1% piperidine alkaloids, a mixture of prosopinine [sedative, hypotensive, spasmolytic, vasodilator, local anaesthetic in mice] and prosopine [prosophylline; excitant and mild local anaesthetic in mice; toxic doses cause convulsions and respiratory paralysis; oral LD50 820mg/kg], as well as (-)-prosafrine and prosafrinine; bark yielded prosopine, prosopinine and isopropinines A & B; roots have also yielded prosopine and prosopinine (Bourrinet & Quevauviller 1969a, 1969b; International… 1994; Omnium Chimique 1969).

P. alba leaf has yielded 0.43% *tyramine*, 0.7% *phenethylamine* and 0.73% *tryptamine* (Graziano et al. 1971), as well as the flavonoids vitexin, isovitexin, luteolin, quercetin, quercetin-3-methyl ether and quercetin-7-glucoside (Gianinetto et al. 1975).

P. alpataco bark has yielded *tetrahydroharman*, cassine and N-methylcassine (Chiale et al. 1982).

P. juliflora has yielded *tryptamine* and *serotonin* from unspecified parts (Smith 1977b; Willaman & Li 1970); leaf has yielded juliflorine, julifloriinine, julifloricine, julifloridine, N-methyljulifloridine, juliprosine and juliprosinene (Ahmad et al. 1989; International... 1994). As P. glandulosa, the leaves yielded 0.31% of a mixture of *tyramine* and N-methyl-*tyramine* (Camp & Norvell 1966), as well as rutin, *apigenin*, luteolin, glucoluteolin, narcissin, isokaempferide, thermopsoside, 3',4',5,7-tetrahydroxy-3-MeO-flavone and 3-glucopyranosyloxy-4',5,7-trihydroxy-3'-MeO-flavone (International... 1994). P. juliflora seeds have been shown to contain 4-OH-pipecolic acid, N-acetyldjenkolic acid and smaller amounts of djenkolic acid (Krauss & Reinbothe 1973).

P. nigra bark has yielded cassine and N-methylcassine (Gianinetto et al. 1980; International... 1994); leaves have yielded 2% alkaloids, including [as % of dry plant] 0.15% *harman*, 0.1% *tetrahydroharman*, 0.3% *tryptamine*, 0.2% N-acetyl-*tryptamine*, 0.4% *phenethylamine* and 0.2% *tyramine* (Moro et al. 1975), as well as the flavonoids vitexin, isovitexin, luteolin, luteolin-7-glucoside, quercetin and isorhamnetin-3-galactoside [cacticin] (Gianinetto et al. 1975).

P. ruscifolia bark has yielded *tetrahydroharman*, cassine and N-methylcassine (Chiale et al. 1982; Gianinetto et al. 1980); leaves have yielded the flavonoids quercetin, vitexin, isovitexin, luteolin and luteolin-7-glucoside (Gianinetto et al. 1975).

P. sericantha bark has yielded *tetrahydroharman*, cassine and N-methylcassine (Chiale et al. 1982); leaves have yielded the flavonoids quercetin, luteolin and isorhamnetin (Gianinetto et al. 1975).

Prosopis africana is a tree 4.5-12(-21)m tall, unarmed, with grey, rough, scaly or fissured bark; young branchlets shortly pubescent or puberulous. Leaves bipinnate; pinnae (1-)2-4 pairs, glandular between most pairs of leaflets; leaflets opposite, in (5-)7-15 pairs, oblong-lanceolate or elliptic-lanceolate, (1.3-)1.5-3(-4) x 0.4-1(-1.5)cm, inconspicuously appressed-puberulous on both sides, apex usually acute or subacute; petiole 2.5-6.6cm long, pubescent or puberulous; rachis (0-)2.7-9.5cm long, pubescent or puberulous, glandular at insertion of pinnae. Flowers creamy-white or yellow-green, fragrant, sessile or nearly so, in 3-6cm long spikes borne on 1-3.5cm long peduncles; calyx 1.5-2mm long, puberulous, gamosepalous, with 5 teeth; petals 5, free, 3-4.5mm long, glabrous or nearly so outside; stamens/filaments 10, fertile, 5.5-6.5mm long; anthers with apical gland which is sometimes sessile and inconspicuous. Ovary hairy. Pods 10-20 x 1.5-3.3cm, black or brown, glossy, subcylindrical or slightly compressed, thickened; seeds ellipsoid, 8-10 x 4-9mm, blackish-brown, glossy.

Wooded grassland, 910-1220m; Uganda, Senegal, Gambia, Guinea, Sierra Leone, Ghana, Nigeria, Cameroon, Sudan (Brenan 1959).

PRUNUS

(Rosaceae)

Prunus africana *(Hook. f.) Kalkman* **(Pygeum africanum** *Hook. f.***)** – ol godjuk, ol kajuk
Prunus emarginata *(Dougl.) Walp.* – bitter cherry
Prunus serotina *Ehrh.* **(P. capuli** *Cav.***; Padus serotina** *(Ehrh.) Borkh.***)** – drunk cherry, wild black cherry, napakwijanik, capulin, usábi
Prunus spp. – wild cherry

This genus, including the sweet cherry [P. avium], apricot [P. armeniaca], peach [P. persica], sweet almond [P. amygdalus var. dulcis] and plum [P. domestica], contains some alkaloids of interest as well as possessing sedative qualities that should be approached with caution. Many species are traditionally used to repel evil, such as in China, where children may wear a peach pit around the neck to keep away demons. Some have been used to make magic wands, and have enjoyed varied uses in love magic. Eating almonds [from P. amygdalus] is said to cure fever and give one wisdom, and eating 5 almonds before drinking alcohol is claimed to prevent intoxication (Cunningham 1994). In India, sweet almonds are said to be a stimulant, nervine tonic (Nadkarni 1976). Peaches are said to induce love and give wisdom; the Japanese believe that peaches may increase fertility (Cunningham 1994). Apricots are said to extend one's lifespan (Bremness 1994). In TCM, P. armeniaca, P. manshurica or P. sibirica kernels ['xing ren'] are used as an antispasmodic sedative [dose 3-5g] in cases of asthma. They are considered incompatible with Astragalus spp. [see *Endnotes*] and **Scutellaria** baicalensis. P. persica kernels are used [5-10g] as an antitussive, as well as being applied as a sedative to treat hypertension (Keys 1976).

In Mexico, P. serotina leaves are used as a depressant, antispasmodic and febrifuge (Jiu 1966). The Tarahumara use large quantities of the leaf and bark to stupefy fish; they use the leaves of the introduced P. persica similarly (Pennington 1958). The bark of 'chokecherry' [P. virginiana] is used in cough medicines, and is sedative and astringent; similarly, the inner bark of 'black' or 'wild cherry' [P. serotina] is a sedative, tonic, digestive and expectorant. These two species, as well as P. cerasus and P. pennsylvanica, are known to the Cherokee, who use the bark from them to treat fever, colds, cough and lost voice. They also use P. persica as a purgative and anthelmintic (Bremness 1994; Hamel & Chiltoskey 1975; Hutchens 1973). The Winnebago drink a tea of P. serotina bark as a tonic, and use the inner bark in combination with other herbs as a food seasoning. They call the tree 'drunk cherry', as eating too many of the fruits causes inebriation (Kindscher & Hurlburt 1998). 'Bitter cherry' [P. emarginata] is used by the Hoop of n. California, who make a tea of the dried bark or keep it under the tongue as a tonic. The leaves may be air-dried and smoked [only a few lungfuls] for a pleasant sedative effect. The Hoop also regard apricot kernels to be "only for shamans" (Pendell 1995), alluding to powerful and probably dangerous properties.

In east Africa, the Masai consume P. africana as a stimulant-excitant, along with other plants [see **Acacia** and *Endnotes*] (Lehmann & Mihalyi 1982). In Germany, P. padus has been known as 'hexenbaum' ['witch tree'] and 'hexenholz' ['witch wood'], hinting at past magical uses (De Vries 1991).

All Prunus spp. contain cyanogenic glycosides, such as amygdalin, prulaurasin and prunasin, in all parts; however, flesh from the ripe fruits is usually safe to eat. During ingestion, when plant parts are crushed or when in contact with water, these compounds convert into hydrocyanic acid [HCN] and aldehydes such as benzaldehyde, the former of which produces cyanide salts and causes serious toxicity. Symptoms may manifest without warning, and include vertigo, mental 'dimness', headache, respiratory failure, loss of voice, muscle spasms, coma and death by asphyxiation. Dried material contains much less potential HCN, and the content is often highest within the kernels (Bremness 1994; Conn 1973; Foster & Caras 1994; Hall 1973; Keys 1976; Pendell 1995), which is why bitter almond oil is so hard to find, and why our parents told us never to eat apricot kernels! Bitter almond oil, by the way, contains on average 95% benzaldehyde and 3% HCN [in the form of prussic acid] (Battaglia 1995), though HCN-free bitter almond oil is available commercially for flavouring purposes. Cherry brandies also have cherry seeds added for flavour and to increase the 'kick', and should probably be approached with caution in excess (theobromus pers. comm.).

Seeds of P. amygdalus var. amara, P. armeniaca, P. cerasus, P. domestica, P. manshurica and P. sibirica, as well as the bark, leaf and flower of P. persica have been found to produce HCN (Huang 1993; Watt & Breyer-Brandwijk 1962). In the case of P. armeniaca, P. manshurica, P. mume, P. vulgaris, P. zhidanensis and P. sibirica, the cyanogenic glycoside present is amygdalin [c.5.4% in seed kernels of the latter], along with the enzyme amygdalase; these react to form HCN (Huang 1993; Shen et al. 1992).

P. amygdalus has yielded *phenethylamine* (Smith 1977a).

P. armeniaca fruit jam was found to contain c.0.0000044% trans-1,2,3,4,5-pentahydroxypentyl-1,2,3,4-tetrahydro-β-carboline-3-carboxylic acid, and c.0.0000168% of the cis-isomer (Herraiz & Galisteo 2002).

P. avium, P. cerasus and P. fruticosa young shoots have yielded *tryptamine*, *tryptophan*, *chlorogenic acids* and coumarins (Feucht & Nachit 1976).

P. domestica fruit has yielded [as µg/g from 'red plum', 'blue-red plum', and 'blue plum', respectively] *serotonin* [10, 8, 0], *tryptamine* [0-2, 2, 5], *tyramine* [6, 0, 0] and *norepinephrine* [present, 0, 0] (Udenfriend et al. 1959).

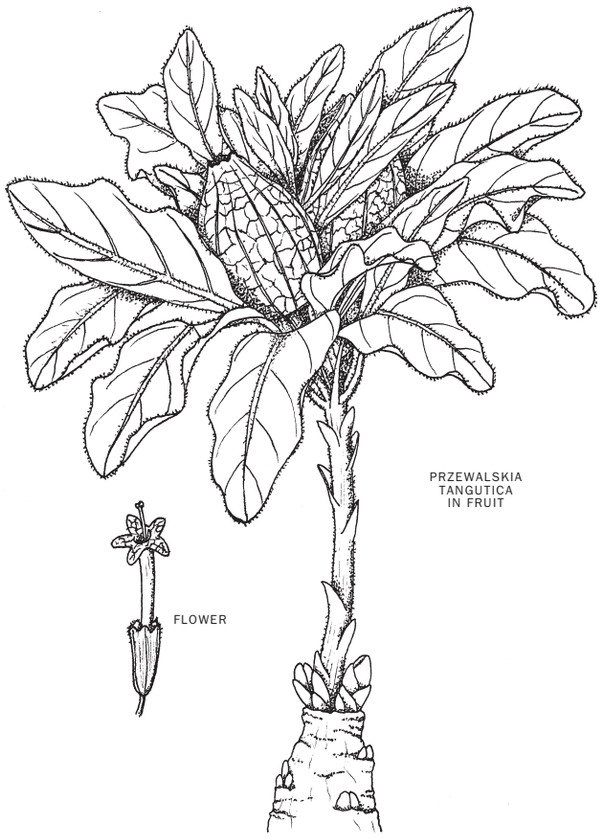
P. padus leaves have yielded *phenethylamine* (Hartmann et al. 1972).

Prunus serotina is a tree to 30m tall, branches reddish-brown, inner bark aromatic, mostly unarmed, deciduous. Leaves simple, oblong-lanceolate to ovate-oblong, apex acuminate to tapered or acute, firm to coriaceous, crenate-serrate with blunt incurved callous teeth, 3.5-15cm long, dark green and lustrous above, pale green beneath; midrib broad and prominent beneath, often villous; petiole 6-25mm long, often 2-glandular. Flowers 7-10mm wide, white or pink, solitary, in slender, elongate racemes 6-15cm long; divergent pedicels 3-10mm long; calyx tube various, partially or completely deciduous in fruit, lobes 5, narrow, acute, often toothed, persistent in fruit; petals 5, spreading; stamens usually 20, perigynous; filaments free, rarely connate; anthers small, 2-celled, opening lengthwise. Carpel 1; style terminal, elongated; ovules 2, collateral, pendulous. Fruit a globose drupe, 7-10mm diam., dark red, becoming purple-black, sweetish to bitter, with an indehiscent or 2-valved smooth or rugged stone; 1-seeded.

Canada, e. & s. U.S., Central & South America (Correll & Johnston 1970; Kirtikar & Basu 1980).

PRZEWALSKIA

(Solanaceae)



Przewalskia tangutica *Maxim.* **(P. roborowskii** *Batalin***; P. shebbearei** *(C.E.C. Fisch.) Grubov***; Mandragora shebbearei** *C.E.C. Fisch.***)** – ma niao pao

This herb, the only representative of its genus (An-ming & Zhi-yu 1986), is used in Tibetan and Chinese traditional medicine as an analgesic, anticonvulsant, antitoxin and treatment for various skin disorders and swellings (An-ming 1986; Peigen & Liyi 1982).

P. tangutica has yielded 0.58-2.72% alkaloids from the leaves – 0.02-0.09% *hyoscine*, 0.33-2.18% *hyoscyamine*, 0.01-0.04% apo-*atropine*, 0.01-0.6% (-)-6-β-OH-*hyoscyamine*, and traces of tropine and cuscohygrine; 0.8-2.72% alkaloids from stems – 0.01-0.09% *hyoscine*, 0.6-1.52% *hyoscyamine*, 0.01-0.03% apo-*atropine*, 0.02-0.14% (-)-6-β-OH-*hyoscyamine*, and traces of tropine and cuscohygrine; 1.82% alkaloids from flowers – 0.08% *hyoscine*, 1.6% *hyoscyamine*, 0.04% apo-*atropine* and 0.1% (-)-6-β-OH-*hyoscyamine*; 0.26-2.07% alkaloids from fruit – 0.02-0.09% *hyoscine*, 0.16-2.07% *hyoscyamine*, 0-0.07% (-)-6-β-OH-*hyoscyamine* and traces of apo-*atropine* and tropine; 0.2-0.27% alkaloids from seeds – almost entirely *hyoscyamine*, with traces of tropine and cuscohygrine; and 2.06-4.01% alkaloids from roots – 0.01-0.05% *hyoscine*, 1.67-3.82% *hyoscyamine*, 0.01-0.02% apo-*atropine*, 0.1-0.68% (-)-6-β-OH-*hyoscyamine*, 0-0.02% daturamine, 0-0.05% tropine and 0-0.03% cuscohygrine (Peigen & Liyi 1982).

Przewalskia tangutica is a herb, rarely a subshrub, densely covered with glandular hairs; stems poorly developed, mostly decumbent and embedded in the soil. Leaves alternate, sessile, often clustering at apex, +-ovate-lanceolate, crenulate, apex rounded, midrib prominent. Flowers usually regular, bisexual, solitary or 2-3 in axillary clusters, on short peduncles 2-3mm long and subfascicled; calyx 5-lobed; corolla infundibuliform, 5-lobed, the lobes usually plaited and imbricate in bud; stamens 5, very short, attached to the limb of the corolla tube. Ovary superior, mostly 2-loculate, with 1 to many ovules in each locule; style 1. Fruiting calyx bladdery, much larger than and enclosing the fruit; capsule globose, slightly elongate, circumsessile from near the middle.

Cold, arid areas at 3200-5000m; in proximity of Qinghai-Xizang Plateau, w. China (An-ming & Zhi-yu 1986; Keng et al. 1993).

PSATHYRELLA

(Agaricaceae/Coprinaceae)

Psathyrella candolleana *(Fr.) Maire* **(P. appendiculata** *(Bull.) Mre. ap. Mre. et al.***; Agaricus appendiculatus** *Bull.***; Hypholoma candolleanum** *(Fr. ex Fr.) Maire***; H. egenulum** *(Berk. et Br.) Sacc.***; H. fragile** *Peck***; Psilocybe albobrunnea** *Lutz non. Beeli***)**

Psathyrella sepulchralis *Singer, Smith et Guzmán* – piule de barda

Psathyrella sp. – kakke chyau ['raven mushroom'], buri chyau ['old ladies' mushroom']

P. sepulchralis was reported to have been used as a 'hallucinogen' by the Zapotecs of Oaxaca, Mexico, though this is suspected of being a confusion with the similar-looking **Psilocybe** zapotecorum, which also grows in the area (Singer et al. 1958; Wasson 1961). It has been presumed to contain *psilocybin* and/or *psilocin*, although the only chemical analysis did not find any. It is worth bearing in mind, however, that the specimens were 8 and 19 years of age (Ott & Guzmán 1976). In Nepal, it was recently discovered that Kirati shamans sometimes consume a [probable] Psathyrella sp. ['kakke chyau', 'buri chyau'] after roasting, "for clarifying the mind" and as "spiritual medicine" (Müller-Ebeling et al. 2002). P. gracilis has been claimed on the Internet to be used as a psychotrope (Toro 2004), but the origin of this information is doubtful.

P. candolleana specimens from Finland were analysed, and only one out of seven samples contained *psilocybin* and *psilocin* [0.004% and 0.005%, respectively] (Ohenoja et al. 1987). Specimens from Sardinia [Italy] yielded 0.007% *psilocybin* and 0.002% *psilocin* (Ballero & Contu 1998). German specimens were shown to contain *psilocybin*, estimated at c.0.05%, as well as *baeocystin* (Gartz 1986b). Japanese specimens yielded 0.08-0.15% *psilocybin* (Koike et al. 1981). Others, however, have found none, in specimens from Switzerland, Canada [Ottawa] and the US [Washington DC] (Stijve & Kuyper 1988). However, the earlier positive reports of *psilocybin* and relatives are now thought by some to have been errors of chemical identification. I am aware of a single bioassay of 10g dry P. candolleana [from Japan], which resulted in no effects (Hoodoo pers. comm.).

Some Psathyrella spp. have been found to contain new *tryptamine* derivatives, psathyrelline I and psathyrelline II (Stijve 2003; Toro 2004).

Psathyrella candolleana has a cap 15-50(-70)mm across, bell-shaped, becoming flattened, convex and expanded when old, surface smooth, dull, hygrophanous, pale ochraceous- or creamy yellowish-brown when moist, cream to almost white, or light lilac-grey, or flushed with brown when dry, centre somewhat darker, radiately wrinkled, faintly translucent-striate when moist, covered with fine, fibrillose white veil when very young, later with fugacious veil-remnants hanging from margin, margin downturned. Stem 40-80 x (3-)4-5(-8)mm, white, apex white-powdered, equal, cylindrical, sometimes enlarged towards base, smooth, shiny, solid when young, hollow when old, sometimes with trace of a ring. Flesh thin, white to grey-brown, watery; taste mild or slightly bitter, smell not distinctive. Gills narrowly adnate, crowded, narrow to broad, white to greyish-lilac when younger, darkening to purplish chocolate-brown and finally brownish-black, edges white-denticulate under hand-lens. Cheilocystidia thin-walled, hyaline, finger-shaped or cylindric; basidia 4-spored; spores light grey-brown to grey-purple to dark brown, almost black, smooth, elliptic or ovate, with a germ pore, 6-8.8 x 3.5-4.5(-5.5)µm. Whole fruiting body fragile. Variable in the field. Spring to late autumn.

Commonly in groups on or near deciduous trees, stumps, buried wood or cut timbers, often in herb-covered places; sometimes on soil amongst grass. Europe, N. America, Australia [Qld, NSW, Vic, SA, WA] (Breitenbach & Kränzlin 1995; Phillips 1981; Shepherd & Totterdell 1988; Young, T. 1994).

PSILOCYBE [including some Hypholoma spp.]

(Agaricaceae/Strophariaceae)

Psilocybe acutipilea *(Speg.) Guzmán*

P. angustipleurocystidiata *Guzmán sp. nov.*

P. antioquensis *Guzmán et al.*

P. aquamarina *(Pegler) Guzmán* **(Stropharia aquamarina** *Pegler***)**

P. arcana *Borovicka et Hlavácek* **(P. cyanescens** *sensu Hlavácek, non Wakefield***)**

P. argentipes *Yokoyama* – hikageshibiretake

P. armandii *Guzmán et Pollock*

P. atlantis *Guzmán et al.*

P. atrobrunnea *(Lasch.) Gillet*

P. aucklandii *Guzmán, King et Bandala* – Auckland Psilocybe, King's Psilocybe

P. australiana *Guzmán et Watling*

P. aztecorum var. aztecorum *Heim emend. Guzmán* – niños, niñitos, apipiltzin ('little children'), niños del agua ('children of the water'), dormilon

P. aztecorum var. bonetii *Guzmán* **(P. bonetii** *Guzmán***)** – niñitos, apipiltzin, dormilon

P. azurescens *Stamets et Gartz* – astoriensis, indigo Psilocybe, flying saucer mushroom

P. baeocystis *Singer et Smith* – baeos, knobbly tops

P. banderillensis *Guzmán*

P. barrerae *Cifuentes et Guzmán*

P. bohemica *Šebek* **(P. coprinifacies** *(Roll.) Pouzar***; P. cyanescens** *sensu A. Pilát, non Wakefield***; P. mairei** *sensu J. Kubicka, non Singer***; Hypholoma cyanescens** *Maire sensu J. Charvát et al.***; H. coprinifacies** *Roll. sensu Herink***; H. worthingtonii** *Fr. sensu K. Kavina***)** – Bohemian Psilocybe

P. brasiliensis *Guzmán*

P. brunneocystidiata *Guzmán et Horak*

P. caerulea *(Kriesl) Noordeloos* **(Stropharia caerulea** *Kriesl***; S. cyanea** *(Bolt. ex Secr.) Tuomikoski***)**

P. caeruleoannulata *Sing. ex Guzmán*

P. caerulescens var. caerulescens *Murrill* **(P. caerulescens var. mazatecorum** *Heim***)** – derrumbes ('landslide'), derrumbe de agua, tsamikishu ('landslide mushroom'), 'nti xi tho ('dear little things that spring forth'), 'nti-xi-tjo-qui-xo, ko:ng ('lord governor'), cañadas, razón-bei, teotlaquilnanácatl ('divine mushrooms that describe or paint')

P. caerulescens var. ombrophila *(Heim) Guzmán, stat nov.* **(P. mixaeensis** *Heim***)** – at-kat, kongk, kee sho, cui-ya-jo-o-su, derrumbe negro, nashwinmush

P. caerulipes *(Peck) Saccardo* – blue foot

P. callosa *(Fr. ex Fr.) Quelet sensu auct., sensu Guzmán* **(P. cookei** *Sing.***; P. semilanceata var. caerulescens** *(Cke.) Sacc.***, var. obtusa** *Bon.* and **var. microspora** *Sing.***; P. strictipes** *Sing. et Smith***)**

P. carbonaria *Sing.*

P. chiapanensis *Guzmán*

P. collybioides *Sing. et Smith*

P. columbiana *Guzmán*

P. coprophila *(Bull. ex Fries) Kummer* **(P. mutans** *McKnight***)**

P. cordispora *Heim* – pi-'tpa ('spindle whorl'), 'ene ti'ic ('thunder's teeth'), atka't, derrumbe negro, dulces clavitos del Señor, nashwinmush

P. crobula *(Fries) Kuhner et Romagnesi* **(P. inquilina var. crobula** *(Fr.) Holland***; P. simulans** *Karst.***; Geophila crobula** *(Fr.) Kuhner et Rom.***)**

P. cubensis *(Earle) Singer* **(P. cubensis var. caerulescens** *(Murr.) Sing. et Smith***; Stropharia cubensis** *Earle***; S. cyanescens** *Murr.***; S. caerulescens** *(Pat.) Sing.***; Naematoloma caerulescens** *Pat.***)** – gold tops, gold caps, cubies, San Insidro, San Insidro Labrador, purple ring, hongos kentesh, di-shi-tjo-le-ra-ja, derrumbe del estiércol de vaca, di-shi-thó-le-nraja, nti-si-tho-yele-nraha, nti-xi-tjole-ncha-ja

P. cyanescens *(Maire) Wakefield* **(Hypholoma cyanescens** *Maire***)** – blue halos, cyans, wavy-caps, Grandote

P. cyanofibrillosa *Stamets et Guzmán* **(P. rhododendronensis** *Stamets nom. prov.***)** – Rhododendron Psilocybe, blue-haired Psilocybe

P. dumontii *Sing. ex Guzmán*

P. eucalypta *Guzmán et Watling* – Eucalyptus Psilocybe

P. fagicola *Heim et Cailleux* – senores principales

P. fagicola var. mesocystidiata *Guzmán*

P. farinacea *Rick ex Guzmán* **(P. albofimbriata** *(Rick) Singer***)**

P. fimetaria *(Orton) Watling* **(P. caesioannulata** *Sing.***; Stropharia fimetaria** *Orton***)**

P. fuliginosa *(Murr.) Smith*

P. furtadoana *Guzmán*

P. galindii *Guzmán*

P. gigaspora *Natarajan et Raman* **(Hypholoma gigaspora** *(Nataraj. et Ram.) Guzmán***; Naematoloma gigaspora** *(Nataraj. et Ram.) Guzmán***)**

Hypholoma popperianum *(Singer) Guzmán* **(Naematoloma popperianum** *Singer***)**
Hypholoma rhombispora *(Guzmán) Guzmán* **(Naematoloma rhombispora** *Guzmán***)**

Psilocybe spp. have long been a respected shamanic ally amongst native peoples of southern Mexico. What is believed to be caps of P. aztecorum in profile have been observed on the statue of the Aztec deity Xochipilli [see **Turbina**] (Wasson 1973). Their use was first noted by Aztec priests, and after centuries of the practice being driven underground by Spanish Catholicism [post-conquest], their use by the Mazatec and others was rediscovered in Oaxaca, Mexico earlier last century. Healers there have been recorded to utilise P. aztecorum, P. caerulescens, P. caerulescens var. ombrophila, P. caerulipes, P. cordispora, P. cubensis, P. fagicola, P. hoogshagenii, P. hoogshagenii var. convexa, P. mexicana, P. wassonii, P. yungensis and P. zapotecorum [see also **Conocybe**, **Panaeolus** and **Psathyrella**]. For divination on illness or other problems, the mushrooms are eaten raw, sometimes washed down with a few sips of water. Dosage amongst the Mixe is 7 pairs of mushrooms for women, and 9 pairs for men. P. caerulescens is reserved only for elders, as it is considered too strong for others. The mushrooms are taken at night in seclusion, away from distracting sounds and interruptions (Heim 1959, 1963b; Heim & Cailleux 1959; Lipp 1990; Rubel & Gettelfinger-Krejci 1976; Schultes & Hofmann 1980, 1992; Singer 1958a; Wasson 1961, 1963).

Since their introduction to the outside world, some indigenous users of the mushrooms have suffered a variety of troubles, including incarceration [in the case of Maria Sabina, who first revealed the extant mushroom ceremony to Gordon Wasson], related to the influx of 'mushroom tourists' looking for an exotic trip (Ott 1993); hence, it is advised that people stick to searching for Psilocybe spp. in their own area. A piece of Maria's advice is also appropriate here – "whoever does it [eat mushrooms] simply to feel the effects can go crazy and stay that way temporarily, but only for a while" (Allen 1997b). Today, shamanic use of the mushrooms is reportedly dying out in Oaxaca, and the fungi are instead being sold to tourists as a source of income. Near San Pedro Nexapa [State of Mexico], P. aztecorum var. aztecorum and var. bonetii are sold in such a way, as 'niños', 'niños de las aguas' or 'apipiltzin' (Guzmán 1978). Around Palenque [State of Chiapas], P. cubensis is sold to tourists as 'hongos' (pers. obs.), a practice likely to occur elsewhere in Mexico, also. In Guatemala, P. mexicana has been found for sale to tourists by native children (Lowy 1977).

P. cubensis and P. subcubensis are also common, and sometimes consumed or sold to tourists, in S. America. In Peru, P. semilanceata and **Copelandia** cyanescens [see **Panaeolus**] are used (Allen & Gartz 1997). P. subcubensis is used 'recreationally' in the Venezuelan Andes, Merida State (Marcano et al. 1994), and Psilocybe spp. are known to sometimes be used shamanically in Iquitos (Trout ed. 1998). P. yungensis has been proposed to have been used in the preparation of a psychotropic drink in Peru [see **Gymnopilus** for full discussion] (Schultes 1967a).

A Psilocybe sp. [called 'nemeyaap'] that is probably P. kumaenorum is eaten raw by senior ritual elders of the Bimin-Kuskusmin of Papua

New Guinea, during the 12th [and highest] stage of initiation, along with a **Boletus** sp. called 'guukhraan', and many other plants [including **Pandanus** nuts, Lithocarpus sp. nuts, **Castanopsis** nuts, **Galbulimima** leaf and bark, **Kaempferia** rhizome] and skin of a frog [Phyrnomantis lateralis – see *Endnotes*]. This Psilocybe is considered very powerful, and is said to be poisonous if used outside of this ritual context (Poole 1987).

In some parts of s.e. Asia and the Pacific Islands [Philippines, Thailand, Sumatra, Java, Bali, Fiji] Psilocybe spp. are both collected wild and/or cultivated in dung [usually of the cattle Bos indicus, B. guarus and B. sundaicus, and water buffalo Bubalus bubalis] for local consumption, but more often, for sale to tourists. They may be sold as is, or prepared into drinks, soups, omelettes and other meals from many restaurants. The Psilocybe spp. involved are usually P. cubensis, P. subcubensis and P. samuiensis – this latter sp. does not grow directly on dung, but on manured soil [see also **Panaeolus**, **Copelandia**]. In Java, only P. subaeruginascens and **Copelandia** cyanescens have been recorded (Allen & Gartz 1997; Allen & Merlin 1992; Gartz et al. 1994).

The properties of local active Psilocybe spp. are known to some in India today, such as in the Palni Hills, where they have been secretively sold to westerners (Gorman 1995). Their use is also quite prominent in Goa [non-traditionally, mostly in connection with the rave scene there], also occurring in Nepal. Again, they are generally sold to tourists, rather than used by the native populace, with some exceptions. The following visionary species have been recorded from India – P. atrobrunnea [Bhubaneshwar], P. aztecorum var. aztecorum, P. cubensis, P. gigaspora, P. indica [Kerala], P. natarajanii, P. pseudoaztecorum [Madras], P. semilanceata [Pune] and P. subcubensis [see also **Panaeolus**, **Copelandia** and **Inocybe**]. P. cubensis and P. subcubensis are also found in Nepal, and Sri Lanka is home to P. goniospora, P. lonchophorus and P. ochreata. Another unidentified species found in Nepal is very similar to P. cubensis and P. subcubensis, but its spores are intermediate in size; it has been proven to be active by psychonauts of N. American origin (Allen & Gartz 1997; Schroeder & Guzmán 1981). It has been proposed that a Psilocybe sp. such as P. cubensis may have been used as 'soma' by the ancient Hindu Vedists [see **Amanita**] (Ott 1998b). Psilocybe spp. are used by Nepalese shamans for shamanic travel, and as a form of 'amrita'. For this, a handful of mushrooms is roasted with salt before consumption. They are sometimes snuffed with other plants, mixed with dampened lime; other ingredients may include **Cannabis**, **Nicotiana**, **Datura** seeds and **Amanita** pantherina (Müller-Ebeling et al. 2002).

Psychedelic inebriations from accidental [mistaken identity] ingestion of P. argentipes have been recorded in Japan (Koike et al. 1981; Musha et al. 1986). In St Petersburg, Russia, P. semilanceata is known to be consumed "by students and actors" (Gurevich 1995). In the Pacific n.w. US, a number of species have been used by locals in the know since at least the late 1960's, including P. baeocystis, P. cyanescens, P. pelliculosa, P. semilanceata and P. stuntzii. Also to be found in this area, but perhaps not as commonly consumed, are P. callosa, P. cyanofibrillosa, P. fimetaria, P. liniformans var. americana, P. silvatica and P. subfimetaria. A recently discovered species [P. azurescens], which is exceptionally potent, has also begun to be collected and consumed, as well as cultivated, in this area. P. cubensis is more commonly used in the southern states (Allen 1997a; Beug & Bigwood 1982; Guzmán et al. 1976; Stamets & Gartz 1995; Weil 1977b; pers. comms.).

In the British Isles and Europe, Psilocybe spp. have been consumed for psychotropic effects since at least the mid 1970's, probably earlier. The most popular has long been the common P. semilanceata, though P. cyanescens, P. bohemica and some **Inocybe** and **Panaeolus** mushrooms have also been so used (Cooper 1977; Gartz 1996; Hyde et al. 1978; Mills et al. 1979; Peden et al. 1981; pers. comms.). Although the possible historic use of **Psilocybe** in Europe is unknown, P. semilanceata is thought to be represented on magical amulets of the 15th and 17th centuries from Spain (Gari 1991).

Australians have also been discovering their local Psilocybe spp. since at least the late 1960's, reputedly first by 'biker-surfer types' (Allen 1998; McCarthy 1971; Southcott 1974). However, the properties of P. cubensis were known in Australia since at least the late 1950's, through unintentional intoxications (Aberdeen & Jones 1958; Cribb & Cribb 1981; Southcott 1974). Nowadays the use of these fungi is relatively scattered in Australia, as many casual LSD-users or drug-naïve persons have consumed them in ignorance, excess and unsuitable settings, spreading fearful and misguided notions about the states they induce. In e. South Australia, Victoria, s. New South Wales and Tasmania the species used are P. australiana, P. eucalypta and P. subaeruginosa. It is possible that P. collyboides and P. tasmaniana have also been used [the former being a dubious identification, made from "specimens collected by police from a fridge in Tasmania" – this species is otherwise not recorded in Australia], as well as several collections that macroscopically do not seem to match with any known species. Usually, however, mushroom users in Australia are unaware of the Latin identity of their fungi, particularly as P. australiana, P. eucalypta and P. subaeruginosa can often be fairly indistinguishable macroscopically [except perhaps to the expert, and there seem to be few true 'experts' in Australian mycology when it comes to this genus]. The common terms 'gold tops' and 'blue meanies' [the latter referring also to some **Panaeolus** and **Copelandia** mushrooms] are often interchanged at will, and applied broadly to any bluing mushroom with a yellowish or orange cap. Correctly, in northern areas, gold tops refers to P. cubensis and P. subcubensis; in southern areas, this term applies to the native Psilocybe spp. listed above. P. semilanceata has also been found in southern Australia, but is rarely used and does not seem to be common. In an isolated area of WA [Balingup], P. subaeruginosa has recently been found and used for visionary purposes [with extensive police interference]. In mid-north NSW as well as Qld and parts of the top end, P. cubensis and P. subcubensis grow on dung [often along with **Panaeolus** and **Copelandia**] and are not infrequently picked and consumed (pers. comms.; pers. obs.; Davis et al. 1978; Guzmán & Watling 1978; Low 1985; McCarthy 1971; Southcott 1974, 1996).

In New Zealand, patterns of mushroom use similar to those in Australia have been observed, with **Copelandia** cyanescens, Psilocybe aucklandii, P. makarorae, P. novae-zealandiae, P. semilanceata and P. subaeruginosa being consumed (pers. comms.; Johnston & Buchanan 1995).

It has been speculated whether Australia's indigenous inhabitants made use of their psychoactive mycoflora – most Australian ethnobotanists will flatly state that the answer is "no, they didn't!" (eg. Low 1985). With a more realistic approach to the scenario, it would be expected that any existing knowledge of such use would not be imparted to researchers, because if it existed, it would be considered extremely sacred and secret, and thus not to be discussed with outsiders or non-initiates (pers. obs.). At any rate, many aboriginal tribes associated fungi of various types with 'mystical' properties. For example, in parts of Central Australia "the Arunta believe that [some] mushrooms and toadstools are fallen stars, and look upon them as being endowed with arungquiltha ['evil magic'], and therefore will not eat them." Apparently, fungi are also held in association with the dreaming and ancestral beings (Kalotas 1996).

In isolated experiments, species such as P. caerulescens, P. mexicana and P. cubensis have been consumed by westerners in the name of science well before the masses caught on (Heim et al. 1958; Hofmann et al. 1959; Stein 1960). Roger Heim reported fairly strong psychedelic effects from his separate experiments with P. caerulescens ['several pairs'], P. cubensis [5 fresh specimens, 120g w/w], P. mexicana [32 fresh specimens, 18g w/w] and P. aztecorum [amount not mentioned]; unfortunately, his eloquent expressions focussed on describing primarily visual and physiological effects, and did not mention the effects on his thought processes (Heim 1957). Sam Stein reported on his experiment with 5g dried P. cubensis [2 specimens], which resulted in a distressing experience (Stein 1958), possibly the first recorded 'freak-out' on mushrooms! As a comparative note of some Central American species, a Western case of administration of 1.5g P. caerulescens [fried in butter] resulted in psychedelic symptoms deemed by the subject as more 'hallucinogenic' and less pleasant than a similar amount of **Panaeolus** sphinctrinus (Stein 1959). Another administration of 1g oven-dried, powdered P. caerulescens caused intially a strong feeling of tiredness, followed by an increasing intoxication which the subject found more psychologically distressing than similar quantities of **Panaeolus** subbalteatus (Stein et al. 1959).

Thanks largely to the efforts of Oss & Oeric (1991), Paul Stamets and J.S. Chilton (1983, 1993) many species of Psilocybe are under cultivation by underground mycologists, including P. azurescens, P. cubensis, P. cyanescens and P. tampanensis. Until recently, various species of *psilocybin*-containing mushrooms [mostly cultivated] were readily and legally available for purchase from vendors in Japan (pers. comms.). In the Netherlands, a variety of species [including P. cubensis, P. mexicana, P. tampanensis and **Copelandia** cyanescens (see **Panaeolus, Copelandia**)] are cultivated in quantity and sold both fresh and dried in 'Smart Shops'. Care should be taken if purchasing fresh mushrooms, as these are often stored in refrigerators, sealed within plastic containers – thus, there is a slight risk of bacterial infection with poorly-stored batches (pers. obs.). One friend developed what appeared to be a severe liver dysfunction lasting several months after consumption of one batch of such commercially-available psychotropic fungi, although it is uncertain whether the mushrooms were responsible (pers. comm.).

Psilocybe spp. have been consumed in a variety of ways. Traditionally, they have often been crushed on a metate, with the juice collected and drunk straight, or mixed with water. Alternately, they may simply be chewed and swallowed [either fresh or dried]. This is not advisable with species growing from dung. When eaten, mushrooms should preferably not be swallowed as soon as they have been chewed. Continuing to chew them like a cud before swallowing or simply holding them in the mouth against the gums or under the tongue ensures some alkaloids are absorbed first orally, and may often result in a quicker onset of effects. There may be mild pangs of nausea when swallowing and while the effects take hold. The former is generally dealt with by washing down each mouthful with a slug of water, and avoiding much contact with taste buds when chewing. The latter may be relieved by chewing a piece of fresh ginger [see *Endnotes*] and controlled breathing. Today, many people prefer to make a mushroom infusion or decoction. Slight acidification of the water used [eg. with lemon juice] will enhance the efficiency of the extraction. Long

boiling times or high temperatures are not necessary and may serve to degrade some of the alkaloids present. The gentlest way of preparing a liquid solution is to simply chop the mushrooms finely, put them in a teapot [with other herbs to taste, and lemon juice or citric acid], pour in some just-boiled water, and let the teapot [with lid on] sit for at least 30mins wrapped in a blanket to keep the heat in [a method suggested by Stamets (1996)]. This works well, and after drinking the strained brew, more boiling water can be added for a later boost if the initial tea was not sufficiently strong. Ginger, liquorice [see **Glycyrrhiza**], peppermint [see *Endnotes*] and honey blend nicely with such mushroom teas. Alternately, some people prefer to powder their dried mushrooms and ingest them in gelatin capsules (pers. comms.; pers. obs.).

These mushrooms contain as their main active chemicals the indole alkaloids *psilocybin* and *psilocin*, often with *baeocystin* and *norbaeocystin* also present. *Psilocin* is a product of the enzymatic de-phosphorylation of *psilocybin*. *Psilocybin* is quite stable, and whole, dried fungi can be kept at room temperature without much loss of alkaloid [freeze-dried fungi are more porous and their contained alkaloids will decompose more quickly at room temperature]. Exposure to light, as well as powdering mushrooms for storage, results in increased degradation of *psilocybin*, though with corresponding increases in *psilocin* content. Lower storage temperatures decrease the rate of degradation, and the best option would appear to be freezer storage of dried mushrooms in a totally airtight container. These fungi should never be dried with excessive heat [ie. not over 50°C].

Many active species exhibit a greenish-blue to vivid dark blue [even blackish] staining when bruised by handling, or ruptured by age or other natural phenomena. Some species exhibit this almost immediately upon handling, while some take several hours or more – also, some only blue on the stem or at the base of the stem, and some active species sometimes do not blue at all [such as many specimens of P. semilanceata]. Some mushrooms in other genera, such as **Boletus**, blue due to unrelated chemical reactions. In *psilocybin*-containing fungi, the staining appears to be due to a compound or compounds produced from the oxidation of the unstable *psilocin*. The exact chemical process occurring here has not yet been fully evaluated, nor have the pigments been identified. The blue pigment formed initially has been suggested to be the O-quinone of *psilocin*. Perkal (1981) suggested it be named psilocinchrome, analogous to the oxidative products of *epinephrine* and *dopamine* [*adrenochrome* and dopachrome, respectively]. This pigment, when observed spectrophotometrically, was seen to soon polymerise, forming what is probably a melanin pigment. Jochen Gartz has also "observed the bluing reaction following removal of the phosphate group from *baeocystin*". N-methyl-*psilocin* [4-OH-*N*-*methyltryptamine*] produces a green-blue pigment on oxidation (Gartz 1996; Hasler et al. 1997; Horita & Weber 1961; Levine 1967; Perkal 1981; Stamets 1996).

Recent phylogenetic research shows that Psilocybe spp. which produce *psilocybin* and/or *psilocin* are unrelated to those which do not. The former group will most likely be re-named as a separate genus, with Psychedelia spp. appearing to be the favoured option (Ivors pers. comms.; Moncalvo et al. 2002). This has provoked controversy in some circles, with the feeling that the proposed name is both unsubtle and inappropriate, and that it will most likely be used to aid in the prosecution of people in possession of such fungi. One scholar has suggested Sabina spp. as a more attractive alternative, in recognition of the famed shaman Maria Sabina (theobromus pers. comm.).

Dosage suggestions, when given below, refer to fresh mushrooms unless stated otherwise, and can only be considered as approximate guides, especially as mushrooms differ in size and potency. Yields are from dry weight, unless stated otherwise. These fungi have effects characteristic of *psilocybin* or *psilocin*, though users often distinguish between the minor subjective physiological effects of different species; thus, some users will prefer to use one species over another. In most countries, ingestion of mushrooms containing *psilocybin* and/or *psilocin* is illegal; in many countries, even harvesting them is seen as an illicit act. In Victoria, Australia, simple possession of 100mg of *psilocybin* or *psilocin* could be perceived as evidence of trafficking – ridiculous, as a bag of mushrooms from one collection, intended for use by a few friends, could easily contain these quantities of *psilocybin* and/or *psilocin*. Such a situation could be made more serious if prosecutors chose to interpret the weight of the mushrooms as being equivalent to the weight of the prohibited alkaloids. Such questionable reasoning has often been applied to LSD, with the weight of the carrier paper being included in the weight of a drug seizure – resulting in prosecutions for quantities of substance far higher than what was actually seized.

P. aeruginosa [Stropharia aeruginosa] has a brilliant blue colour with whitish undertones. It is suspected of being mildly active (Stamets 1996), and has also been reported to be toxic (Connor 1977). No *psilocybin* or *psilocin* have been found, though traces of *tryptophan* have been observed (Leung et al. 1965). Bioassays have been negative (Stamets 1996).

P. arcana from the Czech Republic is similar in some ways to P. bohemica, P. cyanescens, P. mairei, P. serbica (Borovicka & Hlavácek 2001a) and P. moravica (Borovicka 2003), and has been used as a psychotrope (Borovicka pers. comm. 2003). Czech specimens have yielded 0.01-1.15% *psilocybin* and 0.03-0.85% *psilocin* (Stríbrný et al. 2003). Unpublished analysis of unidentified mushroom specimens from Graz, Austria [initially tentatively identified as P. arcana] found 0.13-1.31% *psilocybin* and 0.28-1.76% *psilocin*, making this one of the most potent 'psilocybian' mushrooms in the world [though see P. moravica below]. However these Austrian mushrooms are now believed to represent a species other than P. arcana, possibly a new or little-known one (Anno pers. comm. 2003; Borovicka pers. comm. 2003). P. arcana differs from P. bohemica in having non-decurrent gills, smaller spores and a yellowish-olive coloured cap when dry; it differs from P. serbica in its non-striate cap margin, shorter-necked cheilocystidia and apparent lack of pleurocystidia (Borovicka & Hlavácek 2001a); it differs from P. moravica with its often umbonate cap without greyish tones, its flattened and unmottled stem usually becoming broader upwards, olive-green tones in the bruising reaction, lack of a well developed fibrillose annular zone on the stem, smaller spores and sterigmata, and virtually absent pleurocystidia (Borovicka 2003).

P. argentipes from Japan has yielded 0.002-1.35% *psilocybin* (Koike et al. 1981; Kusano et al. 1986). Musha et al. (1986) wrote that "from our cases it may be said that three specimens [about 1g dry weight] are the suggested dosage to cause poisoning"!

P. atrobrunnea [from e. US, and c. & n. Europe], a non-bluing species, was reported to be *psilocybin*-active on account of a positive bioassay in Norway, though the Norwegian specimens were noted by Guzmán to be closer to P. serbica or P. callosa [but with cheilocystidia of a different size] than to P. atrobrunnea (Guzmán 1983; Stamets 1996). In general this is not considered a psychoactive species (Guzmán et al. 2000), and no *psilocybin* or *psilocin* were found in one analysis of material from Michigan (Leung et al. 1965).

P. aucklandii, growing around Auckland, New Zealand, is known to be moderately active, and the police there are well-aware of its use and habitat, taking advantage of this to make arrests (Guzmán et al. 1993; Stamets 1996; pers. comm.). It contains *psilocin* and *psilocybin* (Johnston & Buchanan 1995).

P. australiana from s. NSW, Victoria and Tasmania [Australia; often in woodchipped garden beds, looks very similar to P. cyanescens] is known to be moderately to strongly active (pers. comms.; pers. obs.), though one study found no indoles in a c.7 year-old collection from Mt. Wilson, near Sydney (Margot & Watling 1981). From limited experience this species seems to lose hardly any potency on careful drying (pers. obs.). It has also been found in New Zealand [near Oratia, 20km west of Auckland] (Guzmán et al. 1993).

P. aztecorum from c. Mexico yielded only 0.2% *psilocybin* and traces of *psilocin* [from 2-yr old samples], but fresh specimens are potent and strongly bluing (Heim & Hofmann 1958; Hofmann et al. 1959; Stamets 1996). P. aztecorum var. bonetii has also yielded *psilocybin* (Ott & Guzmán 1976).

P. azurescens from n.w. US has yielded 1.17-1.78% *psilocybin*, 0.19-0.42% *psilocin* and 0.19-0.41% *baeocystin*; it bruises very strongly, becoming indigo-black in places. It can be cultivated in wood chips and tall grass (Stamets 1996; Stamets & Gartz 1995) and is very potent, with 1-4 specimens constituting an effective dose (Allen 1997a).

P. baeocystis was shown to contain *psilocin*, and traces of *psilocybin* and *tryptophan* (Leung et al. 1965); this species later yielded 0.15-0.85% *psilocybin*, 0-0.59% *psilocin* (Beug & Bigwood 1982), 0.01-0.1% *baeocystin* and 0.0068-0.0086% *norbaeocystin*, and was tentatively observed to contain 4-OH-*tryptamine* (Leung & Paul 1968; Repke et al. 1977). Some internet sources have claimed the detection of traces of many other indole substances in liquid cultures of this mushroom, including *gramine*, indole, *tryptophan*, N-methyltryptophan, 5-methyltryptophan, *5-hydroxytryptophan*, *tryptamine*, *serotonin* creatine sulfate, *DMT* hydrogen-oxalate, *bufotenine* monooxalate, 5-MeO-2-carboxyindole, 3-indoleacetic acid and many other derivatives. However, this is a misinterpretation of Leung et al. (1965), who gave a table of TLC data for the detection of these compounds, but did not report finding them in the fungi analysed (pers. obs.). *DMT* has only been found in Psilocybe spp. which have been artificially fed this alkaloid in the laboratory, though it is a poor metabolic precursor for *psilocybin* and/or *psilocin*, which normally derive from *tryptamine* (Chilton et al. 1979). From 1-4 specimens are said to constitute an active dose (Allen 1997a). This species was once reported to have caused fatal intoxication in a young child, however it has been established that the identification of the mushroom/s responsible was selective and arbitrary - the extent of the 'science' used in this case being that this species was found in the garden where the child lived, but so were other mushroom species, which were ignored by the investigators; there was no evidence that the girl had ingested any Psilocybe. Also, the identity of the Psilocybe sp. in the garden is doubted because the photo used in the journal report seemed to depict P. cyanescens. On top of this, the symptoms observed before the child died 3 days later were consistent with poisoning from toxins found in some **Amanita** and Galerina spp. (Stamets 1996).

P. bohemica from Europe yielded 0.25-1.14% *psilocybin*, 0-0.07% *psilocin* and 0.01-0.03% *baeocystin* (Semerdzieva et al. 1986; Stijve & Kuyper 1985). Czech samples have yielded 0.11-1.34% *psilocybin*, 0-1.27% *psilocin* and 0.008-0.03% *baeocystin*; caps yielded 0.31-1.02% *psilocybin*, 0-

0.05% *psilocin*, and 0.02-0.03% *baeocystin*; stems yielded 0.14-0.54% *psilocybin*, 0-0.07% *psilocin* and 0.01-0.02% *baeocystin*. Highest *psilocybin* levels were usually found in smaller specimens. Cultivated mycelium was shown to contain 0.15-0.21% *psilocybin*, but no other alkaloids were detected (Borovicka & Hlavácek 2001b; Gartz & Müller 1989; Stríbrný et al. 2003; Wurst et al. 1984, 1992). Some European mycologists believe P. bohemica is synonymous with P. cyanescens. It appears to be a separate species, as Gartz demonstrated reproductive barriers between them (Stamets 1996). It also differs from the similar P. moravica with its lack of greyish tones in the cap, relatively narrow and subdecurrent gills, and narrower spores (Borovicka 2003). It can be cultivated in the same way as P. cyanescens and P. azurescens (Gartz & Müller 1989; Stamets 1996).

P. brasiliensis from Brazil is presumed to be active due to its bluing reaction (Guzmán 1983).

P. caerulea from Europe and n.w. US is closely related to P. aeruginosa, but exhibits a more distinct bluing reaction, rather than just a bluish colour, and is presumed to be active (Stamets 1996).

P. caeruleoannulata from Brazil yielded 0.055-0.3% *psilocybin* and 0.2-0.23% *psilocin* (Stijve & de Meijer 1993).

P. caerulescens from Mexico yielded only 0.2% *psilocybin* and no *psilocin* [from aged specimens] (Heim & Hofmann 1958; Hofmann et al. 1959); Brazilian specimens yielded 0.1-0.22% *psilocybin* and 0-0.25% *psilocin* (Stijve & de Meijer 1993). Fresh specimens are moderately to highly active; this species is very bitter. Also found in Venezuela, and once reported from Alabama, though it has not been found there since (Stamets 1996; Stein et al. 1959). P. caerulescens var. ombrophila is known to be active (Ott 1993).

P. caerulipes has been found to contain *psilocybin* and *psilocin* (Leung et al. 1965), and is moderately active (Stamets 1996).

P. callosa from Scotland tested positive for the presence of *psilocybin* (Benedict et al. 1967), as did specimens from other countries. It is found in n.w. US, n. & c. Europe, Siberia and Chile, and is moderately active (Guzmán 1983; Leung et al. 1965; Stamets 1996), with 20-30 specimens constituting a dose (Allen 1997a).

P. collyboides found in a freezer in Tasmania [Australia] has yielded *psilocybin*, but identification of the specimen may have been in error (Guzmán 1983; Southcott 1974).

P. coprophila from Japan yielded 0.08-0.15% *psilocybin* (Kusano et al. 1986); specimens from Europe yielded over 0.1% of an unknown indole compound, but no *psilocybin*, *psilocin* or *baeocystin* (Margot & Watling 1981); Brazilian specimens contained no *psilocybin*, *psilocin* or *serotonin* (Stijve & de Meijer 1993); and specimens from Pacific n.w. US contained no *psilocybin* or *psilocin* either (Beug & Bigwood 1982). Others have occasionally found it to be weakly psychoactive, but losing potency soon after picking (Cooper 1977; Stamets 1996).

P. cordispora is known to be active, but has not been analysed (Guzmán 1983).

P. crobula from n.w. US, Europe and Russia is said to be active, but many have failed to isolate any active tryptamines; it also resembles the deadly Galerina spp. [see *Endnotes*] (Stamets 1996).

P. cubensis is widespread on dung [of cattle, oxen, yaks, water buffalo, horse and elephant] in tropical and semitropical zones worldwide [although oddly, P. cubensis has reportedly been found in Tasmania (Australia) by amateur mycologists, and spores reputed to be from this strain are commercially available] and is extensively cultivated by underground growers in some countries. Strains are of quite variable potency, and 0.2-1.3% *psilocybin* and traces-over 0.35% *psilocin* have been detected (Heim & Hofmann 1958; Hofmann et al. 1959; Stamets & Chilton 1983; Stamets 1996). Samples growing on buffalo dung in Koh Samui, Thailand, yielded 0.042-0.08% *psilocybin*, 0.19-0.58% *psilocin*, less than 0.01% *baeocystin*, 0.007-0.02% *tryptamine* and up to 0.003% urea (Allen & Merlin 1992); others found 0.001-0.01% *baeocystin* (Repke et al. 1977). There is usually more *psilocin* in the stems than in caps (Gartz et al. 1994). Wild Brazilian specimens yielded 0.1-0.36% *psilocybin*, 0.2-0.6% *psilocin* and 0-0.025% *baeocystin*. A cultivated Amazon strain yielded 0.12-0.15% *psilocybin* and 0.1-0.33% *psilocin*; a cultivated Mexican strain yielded 0.12-0.15% *psilocybin* and 0.05-0.5% *psilocin* (Stijve & de Meijer 1993). Specimens cultivated on rice grains yielded 0.95% *psilocybin* and 0.2% *psilocin* (Gartz 1989c). Mycelium has yielded 0.3% *psilocybin* and 0.1% *psilocin* (Gartz 1990a). In submerged culture, up to 1.06% *psilocybin* was produced, but no *psilocin* (Catalfomo & Tyler 1964); saprophytic mycelial cultures yielded up to 0.2% *psilocybin* and 0.02% *psilocin* (Neal et al. 1968). Mycelial cultures have been shown to metabolise tryptamines that are foreign to them, when introduced to the culture – addition of the potent synthetic psychedelic N,N-diethyltryptamine [DET] led to the formation of up to 3.3% 4-OH-DET and 0.01-0.8% 4-phosphoryloxy-DET in the fruiting bodies (Gartz 1989a). An extract of P. cubensis was shown to inhibit *glutamic acid* neurotransmission in rat hippocampus, resulting from activation of 5-HT receptors (Moldavan et al. 2002). The basidiospores have been shown to cause allergic reactions in some people (Lehrer et al. 1994); the cyclophilin Psi c 2 is at least partly responsible for the allergenic activity (Horner et al. 1995).

P. cyanescens from Europe yielded 0.1-0.8% *psilocybin*, 0.04-0.47% *psilocin* and 0.01-0.03% *baeocystin* (Stijve & Kuyper 1985; Wurst et al. 1992); specimens from Czech Republic have yielded 0.13-1.84% *psilocybin* and 0.28-1.81% *psilocin* (Stríbrný et al. 2003); specimens from Sardinia [Italy] yielded 1.24% *psilocybin* and 0.72% *psilocin* (Ballero & Contu 1998). Specimens from the Pacific n.w. US have yielded 0-1.68% *psilocybin*, 0.06-0.96% *psilocin* (Beug & Bigwood 1982; Wurst et al. 1992), 0.004-0.04% *baeocystin* and [tentatively identified] 4-OH-*tryptamine* (Repke et al. 1977). Specimens from Seattle, Washington, also earlier tested positive for *psilocybin*, *psilocin*, and an unidentified compound (Benedict et al. 1962) which was probably *baeocystin*. It can be cultivated on wood chips (Stamets 1993, 1996; Unger & Cooks 1979). Mycelial culture grown on a medium of fallen vegetation from **Tilia**, Quercus, Picea, Pinus and/or **Urtica** yielded 0.35% *psilocybin* (Gartz 1990c). Addition of *tryptamine* to the growth medium can enhance *psilocybin*, *psilocin* and *baeocystin* production [this also works with **Inocybe**, **Pluteus** and **Panaeolus**]. Mycelium cultivated in such a fashion yielded 0.92% *psilocybin* and traces of *psilocin*, compared with unsupplemented mycelial cultures, which yielded 0.21% *psilocybin* and no detectable *psilocin* (Gartz 1990b). Saprophytic mycelial cultures have not yielded detectable levels of psychoactive indoles in other studies (Neal et al. 1968). From 1-3 specimens are said to constitute an active dose (Allen 1997a). Though usually restricted to the northern hemisphere (Guzmán 1983), its presence has been suspected in Australia. One collection of suspected P. cyanescens [growing in woodchips in Melbourne, Australia] was supplied to Gaston Guzmán, who identified the specimens as P. australiana, which is quite similar macroscopically (pers. obs.). P. cyanescens as described by Wakefield is now believed by many mycologists to be a N. American species which has spread to the U.K. and western Europe (Borovicka 2003).

P. cyanofibrillosa from coastal n.w. North America is strongly bluing, but loses most of its *psilocin* in handling; it has yielded up to 0.21% *psilocybin*, and 0.062% *psilocin* (Stamets 1996). Over 70% of the potency is lost after drying; 1-5 specimens may constitute an active dose (Allen 1997a).

P. eucalypta harvested in Talaganda Forest Res., NSW [Australia], was found to contain over 0.1% *psilocybin*, and similar amounts of an unknown indole [specimens about 7 years old] (Margot & Watling 1981); it has also been found in New Zealand [n.w. of New Plymouth] (Guzmán et al. 1993). This species is generally moderately potent (pers. obs.).

P. fimetaria from Scotland tested positive for *psilocybin* (Benedict et al. 1967); it is found in n.w. North America, Chile and Europe (Guzmán 1983). 15-30 specimens are said to constitute an active dose (Allen 1997a).

P. gigaspora [now considered Hypholoma gigaspora] has been shown to contain *psilocybin* and *psilocin*.

P. guzmanii [now considered Hypholoma guzmanii] has been shown to contain *psilocybin* and *psilocin* (Guzmán et al. 2000).

P. herrerae from Chiapas and Veracruz, Mexico, is strongly bluing, and presumed to be active (Guzmán 1983).

P. hoogshagenii is found in Oaxaca, Chiapas and Puebla, Mexico, as well as in Brazil and Colombia; it has yielded 0.15-0.3% *psilocybin*, 0.2-0.3% *psilocin* and 0-0.014% *baeocystin*. P. hoogshagenii var. convexa [which grows near Huautla de Jiménez, Mexico], as P. semperviva, yielded 0.6% *psilocybin* and 0.1% *psilocin* (Guzmán 1983; Heim & Hofmann 1958; Hofmann et al. 1959; Stijve & de Meijer 1993). This latter variant has also been shown, in culture form, to metabolise ergoline alkaloids which are not found in the fungus itself. When treated with *elymoclavine*, the mushroom culture hydroxylated the compound to form *penniclavine* and isopenniclavine; when *agroclavine* was used, *chanoclavine* and isochanoclavine resulted, via the same hydroxylation pathway (Brack et al. 1962).

P. inquilina [P. ecbola] from Europe yielded over 0.1% of an unknown indole, but no *psilocybin*, *psilocin* or *baeocystin* (Margot & Watling 1981); specimens from Pacific n.w. US also contained no *psilocybin* or *psilocin* (Beug & Bigwood 1982).

P. kumaenorum from Papua New Guinea and New Zealand is known to be active (Guzmán 1983).

P. liniformans from Europe yielded 0.16% *psilocybin* and 0.005% *baeocystin* (Stijve & Kuyper 1985); others found 0.59-0.89% *psilocybin* and no *psilocin* in var. americana [which grows in w. US and Chile] (Stamets 1996). 10-20 specimens of var. americana are said to constitute an active dose (Allen 1997a).

P. mairei from n. Africa is strongly bluing, and estimated to be moderately active (Stamets 1996). Specimens from Sardinia [Italy] were found to contain no detectable *psilocybin* or *psilocin* (Ballero & Contu 1998), though it is believed that European specimens identified as P. mairei are in fact P. serbica, and in some cases P. atrobrunnea (Guzmán 1983).

P. makarorae from New Zealand is strongly bluing and contains *psilocybin* and *psilocin* (Johnston & Buchanan 1995), though an earlier study [when this species was still unnamed] found no indole alkaloids in the collection examined. However, the collection was c.12 years old at the time of analysis, and the same study found no indoles in P. australiana and P. subaeruginosa (Margot & Watling 1981). See also the entries for those two species, and the comments for P. aucklandii.

P. mammillata from Florida [US], Jamaica, Mexico and Bolivia bruis-

es blue and is believed to be active (Guzmán 1983).

P. mexicana is found in subtropical Mexico and Guatemala; 0.2-0.4% *psilocybin* and 0.05% *psilocin* have been found in dried fruiting bodies; mycelium yielded 0.2-0.3% *psilocybin*, and traces or no *psilocin* (Guzmán 1983; Hofmann et al. 1958, 1959; Stein et al. 1959). Consumption of 0.5g of sclerotial mass was sufficient to produce the expected effects in one human bioassay (Heim et al. 1958).

P. montana [P. atrorufa] from Europe yielded no *psilocybin*, *psilocin* or *baeocystin*, but it gave over 0.1% of an unknown indole compound (Margot & Watling 1981); others found no indoles in specimens from the Venezuelan Andes (Marcano et al. 1994) or Pacific n.w. US (Beug & Bigwood 1982); some British strains are said to be weakly active (Cooper 1977). It is also found in Russia, Japan (Guzmán 1983) and Australia (May & Wood 1997).

P. moravica has recently been described from Moravia [Czech Republic], and fruits from late September to mid December [although some specimens have been found in late July]. This species is similar to P. arcana and P. bohemica. It has yielded 0.22-0.58% *psilocybin* and 0.61-1.39% *psilocin*, though specimens from lower altitudes yielded an extraordinary 2-2.95% *psilocybin* and 1.18-1.45% *psilocin* (Borovicka 2003).

P. naematoliformis [now considered Hypholoma naematoliformis] has been shown to contain *psilocybin* and *psilocin* (Guzmán et al. 2000).

P. natalensis from Natal, S. Africa bruises blue and is estimated to be moderately active; crude analysis revealed the presence of *psilocybin*, *psilocin* and *baeocystin* (Gartz et al. 1995).

P. neocaledonica [now considered Hypholoma neocaledonica] has been shown to contain *psilocybin* and *psilocin* (Guzmán et al. 2000).

P. novae-zealandiae from New Zealand has been said to be *psilocybin*-active (Ott 1993), though it does not bruise blue (Guzmán 1983; Johnston & Buchanan 1995), and others state it to be 'non-hallucinogenic' (Guzmán et al. 1993).

P. pelliculosa from Pacific n.w. US yielded 0.12-0.71% *psilocybin* (Beug & Bigwood 1982; Tyler 1961) and 0.006-0.05% *baeocystin* (Repke et al. 1977). 20-40 specimens are said to constitute an active dose (Allen 1997a).

P. pseudobullacea from the Venezuelan Andes contains mostly *psilocin*, with some *psilocybin* (Marcano et al. 1994). It is thought that the specimens used in this analysis might represent another species (Guzmán et al. 2000), as P. pseudobullacea is not known to bruise blue (Guzmán 1983).

P. quebecensis from Quebec has yielded *psilocybin* and *psilocin* (Ola'h & Heim 1967).

P. samuiensis from Koh Samui, Thailand yielded 0.23-0.9% *psilocybin*, 0.05-0.81% *psilocin* and 0.01-0.5% *baeocystin*; caps contained more *psilocybin* than stems. Cultivated on a mixture of rye, horse dung, and water, and cased with 2:1 peat/chalk, specimens yielded 0.36-0.73% *psilocybin*, 0.21-0.52% *psilocin* and 0.02-0.05% *baeocystin* (Gartz et al. 1994).

P. semiglobata, a common species in temperate regions long thought to be inactive, has recently been demonstrated to contain *psilocybin* in specimens from n. Italy (Calligaris 1996). Earlier analysis of material from Michigan did not detect any *psilocybin* or *psilocin* (Leung et al. 1965).

P. semilanceata from Norway yielded [w/w] 0.17-1.96% *psilocybin*, 0-0.002% *psilocin*, 0.05-0.34% *baeocystin*, and at least 3 unidentified compounds – smaller specimens had greater *psilocybin* concentration than larger specimens, and *baeocystin* was more concentrated in caps than stems (Christiansen & Rasmussen 1982, 1983; Christiansen et al. 1981a, 1981b, 1984). Finnish samples yielded 0.93-2.37% *psilocybin* [smaller mushrooms again yielding highest levels] and up to 0.02% *psilocin* (Gartz 1996; Jokiranta et al. 1984). Swiss specimens yielded 0.39-0.47% *psilocybin*, 0.088-0.14% *baeocystin* and no *psilocin* (Stijve & de Meijer 1993). German samples yielded 0.44-2.02% alkaloids, consisting of *psilocybin* [0.19-1.45%], *baeocystin* [0.02-0.42%] and no *psilocin*. As with other studies, smaller specimens contained greater concentrations of *psilocybin*, whilst larger specimens gave greater yields in mg per mushroom only because of their greater mass. Bluing was not observed to correlate with *psilocybin* concentrations (Gartz 1986a, 1991). Czechoslovakian samples have yielded 0.76-1.05% *psilocybin*, 0.09-0.12% *psilocin* [caps and stems of separate samples yielded 0.74-0.83%/0.08-0.68% and 0.33-0.45%/0.04-0.1% *psilocybin*/*psilocin*, respectively] (Wurst et al. 1984, 1992); a later study of Czech Republic samples found only 0.12-0.51% *psilocybin* and 0.06-0.27% *psilocin* (Stríbrný et al. 2003). British specimens contained c.0.15% *psilocybin*, but no detectable *psilocin* (Mantle & Waight 1969). Scottish samples also contained *psilocybin* (Benedict et al. 1967). New Zealand samples contained *psilocybin* and *psilocin* (Johnston & Buchanan 1995); and samples from Pacific n.w. US have yielded 0.62-1.28% *psilocybin*, and no *psilocin* – caps contained higher levels than stems (Beug & Bigwood 1982). Samples of unspecified geographic origins have also yielded *psilocybin* [0.003-1.7%], *psilocin* [0.003-0.025%], *baeocystin* [0.02-0.36%] and traces of *norbaeocystin* (Ohenoja et al. 1987; Repke et al. 1977; Semerdzieva et al. 1986; Stijve & Kuyper 1985; White 1979). Swedish samples of this species have also yielded variable levels [up to 0.0146% wet weight] of *phenethylamine* which has been proposed to contribute to tachycardia, anxiety, nausea and vomiting from consumption, through some vague hypothetical mechanism [pure *psilocybin* produced the same effects in some people, though tachycardia was not frequently observed] (Beck et al. 1998); perhaps the weak MAOI activity of *psilocybin* and *psilocin* enables this, as *phenethylamine* is usually orally-inactive. Others have noted that N. American specimens do not appear to exhibit these side effects (Trout pers. comm.). Unidentified indoles and steroidal compounds have also been detected in the species (Toro 2004). Although some collections may be very potent, with weaker strains, 20-40 [or c.4g dry] specimens may be needed for a strong effect, bearing in mind the small stature of this species (Allen 1997a; Hyde et al. 1978; Mantle & Waight 1969). However, doses of 100 and up to 250 [potent, fresh] specimens have been reported (Peden et al. 1981; pers. comm.). In one case, a young man ingested 50-60 specimens; on admission to hospital, tachycardia, mydriasis, hyperreflexia, hypotonia and facial flushing were observed. This person took "between 96 and 120 hours" to return to his previous state of consciousness, with hallucinations and confusion persisting up until this time. Follow-ups on the patient found "no symptoms of a schizophrenic illness" (Hyde et al. 1978). I know several people who have also experienced such extended 'trips' after ingestion of very high doses of P. subaeruginosa, and in these cases also, recovery was complete after approximately 1 week. See also McKenna (1993). There is one report of a young man dying after consuming a large number of P. semilanceata specimens (Gerault & Picart 1996), although the conclusion that this species was responsible for 'death by overdose' has been strongly and convincingly criticised on many points; it seems most likely that in his pickings he inadvertently ate some deadly species as well, with symptoms suggesting muscarine poisoning [see **Amanita**, **Inocybe**] (Gartz et al. 1996). As well as in Europe, P. semilanceata is also found in N. America [n. Cal. to British Columbia], S. Africa, Chile, n. India, Australia [uncommon], New Zealand (Guzmán 1983; Guzmán & Watling 1978) and the UK (Cooper 1977; Gartz 1996).

P. serbica from Serbia, Slovakia and the Czech Republic has yielded *psilocybin* and *psilocin* (Guzmán 1983).

P. silvatica from n. Europe, n. US, and s. Canada [Ontario] contains *psilocybin* and/or *psilocin* (Stamets 1996), and 0-0.02% *baeocystin* (Repke et al. 1977). 20-40 specimens may constitute an active dose (Allen 1997a).

P. stuntzii from Pacific n.w. US yielded 0-0.36% *psilocybin*, 0-0.59% *psilocin* (Beug & Bigwood 1982; Guzmán & Ott 1976) and 0.002-0.02% *baeocystin* (Repke et al. 1977). 20-30 specimens may constitute an active dose (Allen 1997a).

P. subaeruginascens is found in Japan and Java (Guzmán 1983); Japanese cultivated mycelium has yielded 0.017-0.018% *psilocybin* (Koike et al. 1981). Material found growing in n.e. New South Wales [Australia] in 'lantana' mulch, and in association with **Acacia** melanoxylon, is believed by its collectors to be P. subaeruginascens, and has proven very potent when fresh, less so when dry (Recher pers. comm.; pers. obs.). Fragments of dry material [in poor condition] bearing gills were sent to Gaston Guzmán, who identified them as P. subaeruginosa [based partly on the fact that P. subaeruginascens has not been recorded in Australia] (pers. obs.). However, the collector noted their appearance when fresh to be different to that of P. subaeruginosa [and very similar to the photo of P. subaeruginascens in Stamets (1996)], and is not convinced by this diagnosis (Recher pers. comm.).

P. subaeruginosa from Australia and New Zealand is moderately to strongly active (pers. obs.); it has yielded 0.01-0.45% *psilocybin*, with traces of *psilocin* and other compounds that were not identified (Johnston & Buchanan 1995; Perkal et al. 1980; Picker & Richards 1970; Wurst et al. 1984). Specimens from around Melbourne [Victoria], believed to be P. subaeruginosa, yielded 0.03-1.81% *psilocybin* and 0.02-0.18% *psilocin*. One specimen contained 69.4mg *psilocybin* and 16.7mg *psilocin*, which would be sufficient to produce strong effects in at least 2-3 people. Analysed separately, caps yielded 0.05-1.93% *psilocybin* and 0.06-0.32% *psilocin*; stems yielded 0.04-1.52% *psilocybin* and 0.01-0.15% *psilocin* (Perkal 1981). A recent analysis found 0.107-0.112% *psilocybin* and only 0.0011-0.0019% *psilocin* (Anastos et al. 2006). One study found no indoles in a collection of this species from Mt. Lofty, near Adelaide [SA] (Margot & Watling 1981). Specimens contain, on average, 90% water (Perkal 1981).

P. subcaerulipes from Japan has yielded 0.34-0.81% *psilocybin* (Kusano et al. 1986).

P. subcubensis has an appearance and distribution similar to that of P. cubensis, and has yielded 0.37% *psilocybin*, 0.26% *psilocin*, 0.006% *baeocystin* and 0.01% *tryptophan* in samples from Koh Samui, Thailand (Allen & Merlin 1992); Venezuelan Andean specimens contained mainly *psilocybin*, with smaller amounts of *psilocin* (Marcano et al. 1994). There is a report of a young man dying after consuming cultivated P. subcubensis, although the title of the article is misleading; he was found in an irrigation canal and is believed to have died from hypothermia [the abstract does not state whether there was any evidence of drowning], not from any toxic effect of the mushroom (Gonmori & Yoshioka 2002).

P. subfimetaria from n.w. US and Chile contains *psilocybin* (Guzmán 1983).

P. cf. subyungensis from Brazil yielded 0.5% *psilocybin*, 0.4% *psilocin* and 0.033% *baeocystin* (Stijve & de Meijer 1993).

P. tampanensis cultivated on 6% malt agar and **Lolium** seed yielded 0.34-0.68% *psilocybin*; sclerotia on **Lolium** yielded 0.11-0.32% *psilocin*; and sclerotia on malt agar yielded 0.41-0.61% *psilocybin*, 0.21-0.52% *psilocin* (Gartz et al. 1994). It is native but rare in Florida, known only from the type location [near Tampa] (Guzmán 1983), and is now widely cultivated (Stamets & Chilton 1983).

P. tasmaniana from Australia and New Zealand has been suggested to contain *psilocybin* based on its psychoactivity (Stamets 1996).

P. thailandensis has yielded 0.055-0.075% *psilocybin* and 0.1-0.6% *psilocin* (Stijve & de Meijer 1993).

P. uruguayensis from Brazil yielded 0.085-0.14% *psilocybin*, 0-0.01% *psilocin* and 0.015-0.02% *baeocystin* (Stijve & de Meijer 1993).

P. venenata from Japan bruises blue and has caused human inebriations (Guzmán 1983; pers. comms.).

P. wassonii from Mexico is strongly bluing and estimated to be strongly active; only 0.02% *psilocybin* and 0.01% *psilocin* were found in aged specimens (Heim 1958; Stamets 1996; Tamm 1962).

P. wassoniorum from Veracruz, Mexico, bruises blue and is thought to be active (Guzmán 1983).

P. weilii from n. Georgia [US] has yielded 0.61% *psilocybin*, 0.27% *psilocin*, 0.05% *baeocystin* and 0.32% *tryptophan* (Stamets 1996). It is very similar in appearance to P. caerulescens, except for the presence of pleurocystidia in P. weilii (Guzmán et al. 1997).

P. yungensis from Colombia, Ecuador and Mexico is known to be active; despite its known psychoactivity, repeated analyses by Albert Hofmann found no *psilocybin* or *psilocin* (Guzmán 1983; Heim & Cailleux 1959).

P. zapotecorum from s. Mexico and subtropical S. America has yielded 0.3-0.5% *psilocybin* and 0-1.0% *psilocin* (Guzmán 1983; Heim & Hofmann 1958; Hofmann et al. 1959; Ott & Guzmán 1976); Brazilian specimens yielded 0.06-0.3% *psilocybin*, 0.05-1.0% *psilocin* and 0-0.02% *baeocystin* (Stijve & de Meijer 1993).

Other species listed at the head of this entry are bluing species that are believed to be psychoactive, yet are not known to have been chemically analysed (Guzmán 1983, 1995; Guzmán et al. 2000, 2002; Ott 1993).

Also, the closely related Hypholoma popperianum and H. rhombispora have been shown to contain *psilocybin* and *psilocin* (Guzmán et al. 2000). H. aurantiaca from Australia was found to contain 0.097-0.099% *psilocybin* but no *psilocin*, as well as an unidentified compound (Anastos et al. 2006). The few psychoanuts who have eaten this species reported diarrhoea but no psychedelic activity. Based on this some people suspect the analysis to have given a false result (pers. comms.). It is widespread [also found in Europe and N. America] and might have regional differences in chemistry.

H. fasciculare [Naematoloma fasciculare; 'sulphur tuft'] was claimed by one author to have caused 'hallucinations' ["especially auditive ones"] as well as more serious toxicity (Toro 2004, quoting Giacomoni); it is generally reported to be bitter and poisonous. There have been fatal cases, in which post-mortem examination revealed damage to the liver, cardiac muscle and brain cells. An ethanolic extract given to rats [i.p.] had diuretic and parasympathetic activity. The species has yielded triterpenes called fasciculols [some of which caused paralysis and death when injected i.p. into mice], compounds called hypholomins and fasciculins (Bresinsky & Besl 1989; Connor 1977; Diak 1977), small amounts of muscarine and epi-muscarine [see **Amanita**] (Stadelmann et al. 1976), the amines *choline*, amylamine, methylamine, propylamine, cadaverine, putrescine, *phenethylamine* and betaine, the amino acids arginine, alanine, *GABA*, *glycine*, *tryptophan*, leucine, lysine, ornithine and valine, the purines alantoine and *guanine*, the sterols cerewisterol, ergosterol, ergosterol peroxide and stigmasterol, and the sugars glucose, mannitol, mannose, trehalose and xylose (Diak 1977).

Psilocybe cyanescens has a cap (1-)2-5(-7.5)cm diam., subconic or convex to campanulate, becoming irregularly expanded plano-convex or applanate to depressed, sometimes subumbonate, glabrous, margin slightly striate when moist, viscid, hygrophanous, orangish-brown or chestnut colour, fading to yellowish, straw-colour, or ochraceous; easily bruising blue. Stem (4-)6-9(-11)cm x (3-)4-6(-7)mm, equal, cylindrical, or bulbous at base, straight or flexuous, hard and cartaliginous, solid to hollow, surface white to whitish, silky-fibrillose or scabrous towards base, base with conspicuous white rhizomorphs; readily bruising blue. Gills adnate to sinuate, yellowish- or orangish-brown to violaceous-brown, sometimes mottled, edges concolorous or nearly whitish. Spore print dark brown-violet or fuscous; spores (8.8-)11-13.2(-15.4) x (6-)6.6-7.7(-8.5) x 5.5-7µm, elongate-ellipsoid, thick-walled, dark yellowish-brown, with distinct broad apical germ pore; basidia (2-)4-spored, hyaline, vesiculose-subpyriform, sometimes with slight median constriction; pleurocystidia more frequent near edge of gill; cheilocystidia abundant, with a long neck, bifurcate or simple. Fr. Oct.-Dec. or later [though Sep. fruiting has been reported in Scotland (pers. comm.)].

Usually gregarious, sometimes forming rings, on very rotten wood mixed with soil, on sawdust or soil mulch containing wood chips or bark, in deciduous forests, also very common in gardens under bushes, very rarely in grasses; Great Britain, Netherlands, Germany, n.w. North America [Vancouver to Cal.] (Guzmán 1983).

The Australian species P. australiana, P. eucalypta, P. subaeruginosa and P. tasmaniana can appear very similar to one another macroscopically, and can vary greatly in appearance; they can also overlap to varying degrees in their choice of substrate, with the possible exception of P. tasmaniana. Some researchers have attempted to show that these species [or at least some of them] are all synonymous (Chang & Mills 1992), an opinion shared by some amateur mushroom enthusiasts with extensive picking experience and access to a good microscope (Bluemeanie pers. comm.). Stamets (1996) disputed the validity of this argument based on inconsistencies in the identification of the purported P. subaeruginosa studied by Chang & Mills (1992). Recent independent studies have found that P. subaeruginosa and P. australiana [collected from a wide variety of locations in southern Australia] are indistinguishable microscopically and should probably be regarded as the same species (Bluemeanie pers. comm.). Furthermore, Guzmán's description of P. subaeruginosa, describing chocolate-brown pleurocystidia and cheilocystidia for that species (Guzmán 1983), was based on analysis of only a small collection of samples, and later studies have found no coloured cystidia in collections of P. subaeruginosa. This brings doubt to the actual identity of the material studied by Guzmán (Johnston & Buchanan 1995).

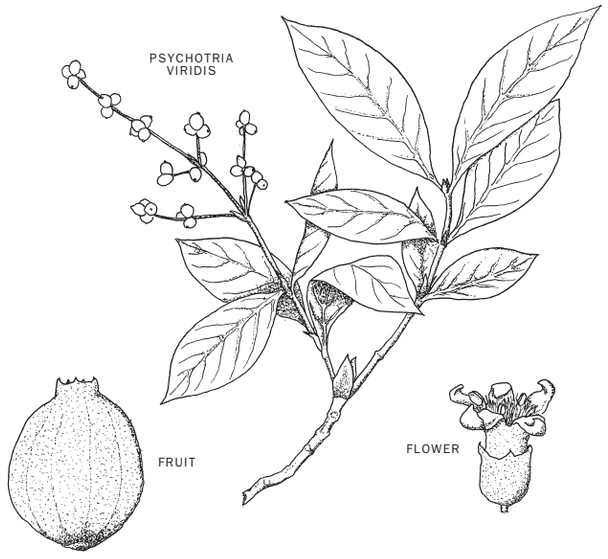
To aid in attempted separation of collections from s.e. Australia [assuming these species are in fact all separate], the following comparison is given (from Guzmán & Watling 1978):

	P. australiana	P. eucalypta	P. subaeruginosa	P. tasmaniana
Habitat	woody or leafy debris	soil with wood debris, or in moss	decaying leaves or debris mixed w. dung	dung [usually kangaroo]
Spore				
- length µm	(10-)12-14(-15.9)	(9.3-)9.9-12(-13)	(11-)13.2-14.3(-16.5)	(10-)12-13(-15.4)
- breadth µm	(5.5-)6.6-7(-7.7)	(6-)6.6-7.1	6.6-7.7	7.1-7.7(-8.8)
- width µm	6-7	5.5-6.6	6.7	7.1-7.7(-8.8)
Pleurocystidia	hyaline	hyaline	hyaline, brownish-grey	hyaline
- length µm	22-33	17-30	24-47.3	19-24
- breadth µm	7.7-11	5.5-7.7	8.8-16.5	6.6-8.8
Cheilocystidia	neck short, 4µm or less, simple	neck short, 5µm or less, simple	neck short, 4µm or less, simple	neck long, >5µm, often bifurcate
- length µm	17-23	15-25	26-29	22-33
- breadth µm	5.5-7.7	4.4-6.6	8-11	4.4-9.9

Special care should be taken when harvesting wood-decaying Psilocybe spp., as some may be confused with potentially deadly Galerina spp. [such as G. autumnalis] which share the same habitat. Fortunately, the rusty brown spores of the latter fungi help distinguish them from the dark purplish spores of the former.

PSYCHOTRIA

(Rubiaceae)



Psychotria alba *Ruiz et Pav.* **(Mapouria alba** *(Ruiz et Pav.) Müll.-Arg.***; M. rigida** *Rusby***; Uragoga alba** *(Ruiz et Pav.) Kuntze***)** – yagé, tupamaqui, ucumi-micuna

Psychotria brachybotrya *Müll.-Arg.* **(P. iquitosensis** *Standl.***)** – tan'-su

Psychotria carthaginensis *Jacq.* **(P. ficigemma** *DC.***; P. fockeana** *Miq.***; P. foveolata** *Ruiz et Pav.***; P. sagraeana** *Urb.***; Uragoga carthagenensis** *(Jacq.) Kuntze***)** – wy-soo-dö, yagé, yagé-chacruna, rami appane, rani appani, sameruca

Psychotria colorata *(Willd. ex Roem. et Schult.) Müll.-Arg.* **(Cephaelis amoena** *Bremek.***; C. colorata** *Willd. ex Roem. et Schult.***)** – perpetua do mato

Psychotria horizontalis *Sw.* **(Myrstiphyllum horizontalis** *(Sw.) Millsp.***; Uragoga horizontalis** *(Sw.) Kuntze***)** – tupamaqui

Psychotria marginata *Sw.* **(P. nicaraguensis** *Benth.***; Myrstiphyllum marginatum** *(Sw.) Hitchc.***; Uragoga marginata** *(Sw.) Kuntze***)** – yagé, sanaguillo

Psychotria poepiggiana *Müll.-Arg.* **(Callicocca tomentosa** *(Aubl.) J.F. Gmel.***; Cephaelis hirsuta** *M. Martens et Galeotti***; C. tomentosa** *(Aubl.) Vahl***; C. vultusmimi** *Dwyer***; Evea tomentosa** *(Aubl.) Standl.***; Tapogomea tomentosa** *Aubl.***; Uragoga tomentosa** *(Aubl.) K. Schum.***)** – oreja del diablo ['devil's ear'], chacruna, picho e mula, boca pintada, bimichëxë

Psychotria stenostachya *Standl.* – yagé, rumo sacha

Psychotria viridis *Ruíz et Pav.* **(P. glomerata** *Kunth***; Palicourea viridis** *(Ruiz et Pav.) Roem. et Schult.***)** – chacruna, sami ruca, amiruca panga, o-pri-to, kawa, rami appane, suija, tupamaqui, yagé

P. viridis is the most common *DMT*-containing plant admixture in ayahuasca brews of Amazonia [see **Banisteriopsis**], used in Colombia, Ecuador, Peru, and some isolated areas of Brazil. It is the favoured additive amongst the modern ayahuasca churches, Santo Daime and União do Vegetal [UDV]. The UDV are also said to use P. alba, though it is apparently only c.60% as potent. The leaves of the chosen Psychotria sp. are added to the brew to create the majority of entheogenic effects. Sometimes, P. carthaginensis, P. horizontalis, P. marginata or P. stenostachya are used instead. Reports of P. psychotriaefolia being used in ayahuasca, and containing *DMT*, were in error, and should have referred to P. viridis. Several unidentified species have also been added to ayahuasca – including 'batsiwaka' and 'pishikwa' of the Sharanahua, 'matsikawa' and 'naikawa' of the Cashinahua [thought to be the same species as 'batsikawa'], and 'urubambashi' of the Machiguenga. The latter tribe also separately use a species known as 'sampakatishi' – its leaf juice is applied as eyedrops before hunting. After initial burning sensations subside, the senses are said to be sharpened. The drops are also used to treat migraine. The Andoke use P. brachybotrya in a similar way, though prepared differently. The crushed leaves are infused in water, which is then used as eyedrops a few drops at a time. It is said to give "clear vision...to see with understanding" (Duke & Vasquez 1994; Ott 1993, 1994; Pinkley 1969; Prance 1970; Russo undated; Schultes 1969a, 1969c, 1972; Schultes & Raffauf 1990; Trout pers. comm.).

The Makuna say of P. carthaginensis that the fruits, if eaten, cause a poisoning resulting in several days of weakness, fevers, nausea and disturbed vision. Fruits of P. involucrata and P. nudiceps are also said to be toxic when eaten (Schultes 1969a). Still in the Amazon, flowers of P. colorata are used to treat earache, and the roots and fruits treat abdominal pain (Elisabetsky et al. 1995; Verotta et al. 1998). The Peruvian P. poepiggiana is used medicinally by the Yahua, and its leaves have proven highly active as a non-traditional ayahuasca-additive. Though the Yahua do not use this species as an entheogen, they do use two other unidentified species as ayahuasca-additives – P. 'huarmi chacruna' [of which roots are regarded most active, though leaves are also highly active] and P. 'lucero sanango' [considered dangerously potent] (pers. comm.).

In Queensland, Australia, P. fitzalani is used as an aphrodisiac in the same way as **Pithecellobium** grandiflorum (Cribb & Cribb 1981). In Malaya, P. sarmentosa and other unidentified Psychotria spp. are used for their roots or juice in the manufacture of dart-poisons (Bisset & Woods 1966). P. insularum leaves and stems are used in Samoa to treat fever, abdominal disturbances and incontinence, amongst other complaints. Extracts showed CNS-depressant effects in mice (Cox et al. 1989). In the West Indies, seeds of P. brachiata, P. laxa, P. marginata, P. nervosa and P. uliginosa have been used as coffee substitutes [see **Coffea**] (Von Bibra 1855). Finally, the root of the Brazilian P. ipecacuanha is the herbal drug 'ipecac', or 'ipecacuanha', used in many parts of the world as an emetic, expectorant and diaphoretic (Chopra et al. 1965).

Psychotria spp. seem to be quite variable in alkaloid content, and some psychonauts in the US have had difficulty in obtaining a full-strength ayahuasca experience using locally grown material.

P. carthaginensis has yielded from 0-0.66% alkaloids, when present being made up of 99% *DMT*, and traces of *N-methyltryptamine* [*NMT*] and 2-methyl-THβC. Some samples containing no alkaloids were from sterile collections, and thus identification may have been in error. Leaf-extract from an alkaloid-free sample was sedative in mice at very high doses [1g/kg, i.p.] (Leal & Elisabetsky 1996; McKenna et al. 1984a; Rivier & Lindgren 1972).

P. colorata flowers yielded 0.51-0.8% alkaloids, mostly (8-8a),(8'-8'a)-tetradehydroisocalycanthine 3a(R),3'a(R), as well as (-)-calycanthine, isocalycanthine [see **Calycanthus**], hodgkinsine, quadrigenine C and (+)-chimonanthine. Leaves yielded 0.2% alkaloids, consisting of calycanthine, isocalycanthine and quadrigenine C. The flower alkaloids showed marked opioid-like analgesic activity, acting on both mu- and kappa-opioid receptors (Elisabetsky et al. 1995; Verotta 1998).

P. viridis leaves have yielded 0.11-0.34% alkaloids, of which c.99% may be *DMT*; some contain traces of *NMT* and 2-methyl-THβC. One sample tested contained no *DMT* in its 0.11% alkaloids, only 85% *NMT* and 12% 2-methyl-THβC (McKenna et al. 1984a; Rivier & Lindgren 1972). Apparently, the root bark is considerably higher in alkaloid content (pers. comm.). On occasion in the past, P. viridis has been misidentified as P. psychotriaefolia, both in the chemical and ethnobotanical literature (Ott 1994).

P. sp. 'matsikawa' is said to contain no alkaloids. P. sp. 'naikawa' yielded 0.16-0.22% *DMT*. A brew made using P. sp. 'batsikawa' and P. sp. 'pishikawa' also contained *DMT* (Ott 1993, 1994).

Some potentially toxic and probably non-psychoptic species from continents and countries other than South America are discussed below.

P. beccaroides from New Guinea, P. forsteriana from Vanuatu, and P. lyciiflora and P. oleoides from New Caledonia contain complex indole alkaloids called psychotridines – *NMT*-derived alkaloids made by linking 2-8 pyrrolidinoindoline groups. They are potently cytotoxic against rat hepatoma and human leukaemia cell lines, inhibit platelet aggregation, and are antibacterial, strongly sedative and analgesic in mice (CSIRO 1990; Jannic et al. 1999; Saad et al. 1995). P. beccaroides stem bark yielded 0.44% alkaloids, mostly psychotridine. The alkaloids had little effect in animals when given orally, except in very high doses; 15mg/kg [i.p.] in cats caused "emesis and tachypnea; 35mg/kg caused a broad spectrum of activity including CNS depression of long duration, dyspnea, ataxia and deep respiration." (CSIRO 1990). P. forsteriana has yielded vatine and vatine A. P. lyciiflora leaves yielded hodgkinsine, meso-chimonanthine and N-desmethyl-meso-chimonanthine. P. oleoides leaves yielded psychotridine, isopsychotridine B, isopsychotridine E, hodgkinsine, quadrigemine, quadrigemine C [antagonises growth hormone secretion in rat pituitary], caledonine and oleoidine (Jannic et al. 1999; Saad et al. 1995).

P. coelospermum leaves and stems yielded a complex mixture of alkaloids [which were specifically noted as not similar to those of P. beccaroides], which were +- inactive orally in animals. In cats and dogs, 1mg/kg [i.v.] caused "salivation, defaecation and lacrimation; 5mg/kg produced decreased activity, convulsions, and death." In cats, 0.5mg/kg [i.v.] had prolonged hypotensive effects (CSIRO 1990). Leaves and root-bark of P. daphnoides, and leaves, roots and bark of P. loniceroides [both from Queensland, Australia] tested negative for alkaloids (Webb 1949). Caution should be exercised with untested species, as some of these non-entheogenic alkaloids, as listed above, are highly toxic.

Psychotria viridis is a shrub or small tree to 4.3m tall, glabrous throughout; stems erect, terete, much-branched; branches terete, obsoletely 4-angled above, compressed. Leaves short-petiolate, opposite, entire, obovate or obovate-oblong, acute or short-acuminate, base long-cuneate, 8-15 x 2.5-5cm, underside minutely pitted, veins near base minutely pitted, bent inward; stipules opposite, large, thin, lanceolate, acuminate, connate, caducous, brownish; petiole longitudinally grooved. Inflorescence a terminal spike-like subpaniculate raceme, pedunculate, shorter than leaves, up to 10-12cm long, lower branches +- verticillate; peduncles 4-angled, compressed, brachiate; flowers sessile in distant glomerules, very small, crowded, usually 4mm long; calyx very small, 5-lobed, lobes acute, persistent; corolla small, greenish-white, funnel-shaped, not basally gibbous, upper part of throat hirsute, expanded, 5-limbed, limbs ovate, acute, spreading, apex reflexed; stamens 5, filiform, filaments short, inserted below throat of corolla; anthers included, linear, incumbent, basally bifid, bilocular. Ovary subrotundate, unilocular, umbilicus prominent; style filiform; stigma bilobed, lobes oblong, moderately thick, obtuse. Fruit small, drupaceous, crowned, globose, ovoid, 2-seeded; seeds bony, ovate, convex, 5-grooved, smooth on other surface.

In forests throughout Amazon Basin, north to C. America and Cuba (Ruiz & Pavon 1799; Schultes & Hofmann 1980).

'Ayahuasqueros' may sometimes identify Psychotria spp. suitable for use by the presence of a double line of tiny spine-like swollen glandular structures on the midrib of the underside of the leaf. According to preliminary testing, these structures seem to be an indicator of strains containing *DMT*, at least for P. viridis (Leal & Elisabetsky 1996; McKenna et al. 1984a).

To cultivate from seed, all traces of fruit pulp must first be removed – this is sometimes aided by soaking in hydrogen peroxide. Germinate seeds in sterilised seed-raising mix or sand in a humidity chamber; bottom-heat may be needed. Seeds may take many months to germinate. Plants prefer warm, moderately humid conditions; frost sensitive. Water regularly. Some species may respond well to leaf-propagation [sometimes, fallen leaves from a plant will root and re-shoot without any help]. For this purpose, the leaves may be folded 'concertina-style' to slightly break the midrib in several places, and then placed on soil or slightly buried. Each leaf may grow roots and sprout new plants using this method. A humidity chamber may aid this process (pers. comms.).

PTEROCEREUS

(Cactaceae)

Pterocereus gaumeri *(Br. et R.) MacDougall et Miranda* **(Anisocereus gaumeri** *(Br. et R.) Backeb.***; Pachycereus gaumeri** *Br. et R. sp. nov.***)**

P. gaumeri has been shown to contain less than 0.01% *mescaline*, c.0.1% *DMPEA* and c.0.01% 3,5-dimethoxy-4-OH-*phenethylamine* (Ma et al. 1986), as well as 0.062% pterocereine [6,7-dimethoxy-5-glucosyloxy-1-hydroxymethyl-2-methyl-THIQ], 0.164% deglucopterocereine [probably an artefact of extraction; formed from acid hydrolysis of pterocereine; similar structure to *gigantine*] (Mohamed et al. 1979) and 0.038% deglucopterocereine N-oxide (Pummangura et al. 1982b).

Pterocereus gaumeri is a long, slender cactus, somewhat tree-like, to 7m tall, greyish blue-green in colour, stems with 3-4 almost wing-like thin ribs, 3-4cm high; areoles large, yellowish-brown, 1-2.5cm apart, each bearing 3-6 brown slender spines 1-3cm long. Flowers borne laterally, diurnal in early summer, short and fat, petals curving backwards, c.5cm long, yellowish-white to yellowish-green; scales of flower tube and ovary more or less foliaceous, drying black and thin, with brown-felted areoles; ovary scales linear, puberulent. Fruit 3-4cm diam., becoming dry and globose, with small scales at base with felted axils, scales +- foliaceous, drying black and thin; seeds numerous, brown, 4mm long.

Yucatan; Mexico.

Needs bright light and enriched mineral compost, min. temp. 15°C (Britton & Rose 1963; Innes & Glass 1991; Trout & Friends 1999).

PTYCHOPETALUM

(Olacaceae)

Ptychopetalum olacoides *Benth.* **(Liriosma ovata** *Miers***; Dulacia inopiflora** *(Miers) Kuntze***; D. ovata** *(Miers) Kuntze***)** – muira puama, mara puama, potence wood, potency wood

Ptychopetalum uncinatum *Anselmino* – muira puama

'Muira puama' is a popular aphrodisiac in parts of Brazil, particularly in the Orinoco basin and parts of the Amazon. Natives either chew the bark of the tree, or boil 2-4 tablespoons of root and bark shavings for 15 min. in a pint of water, each partner drinking a cup of the liquid 1-2 hours before sexual intercourse. P. olacoides is considered interchangeable with P. uncinatum (Miller 1985; Mors & Rizzini 1966), and in the herbal trade they are sometimes adulterated with the roots of the guava tree, Psidium guajava [see *Endnotes*]. In the Rio Negro and other parts of the Brazilian Amazon, P. olacoides stem and root [of young plants] are used to treat neuromuscular problems. A bath of the root decoction treats paralysis and beri-beri, and is said to prevent baldness. Taken internally, the tea is an aphrodisiac that treats impotence, rheumatism, dysentery, grippe, neuraesthenia and cardiac and gastrointestinal aesthenia (Da Silva 1927; Schultes & Raffauf 1990). 'Caboclos' [Portuguese/indigenous inhabitants] in the Amazon use the roots in alcoholic tincture as a nervous stimulant and aphrodisiac (Siqueira et al. 1998).

The effects of muira puama may be so subtle as to be unnoticeable, yet most people do notice the effects, which are similar to those of yohimbe [see **Corynanthe**]. Some people have described very mild 'LSD-like' symptoms accompanying the spinal tinglings, and some people experience mild nausea or gastric discomfort. Some people may have an allergic reaction to this herb. This may be tested for by shallowly scratching the skin with a sterilised pin, and applying a small sample of muira puama to the scratch – irritation within the hour indicates a likely allergic reaction (Miller 1985; pers. comm.). From 0.6-1.2g of the bark may be effective as a nerve tonic. Apparently, the wood-chips have even sometimes been added to psychotropic smoking mixtures (Rätsch 1998), though it is questionable whether any of the [undetermined] active principles would survive combustion.

P. olacoides contains resinous principles with CNS-stimulating effects, which are best extracted in alcohol (Miller 1985). Constituents include liriosmin (Schermerhorn et al. ed. 1957-1974), muirapuamine [0.055% of root; found mostly in bark, traces in wood], two abietic acids [0.6 and 0.7% of root], 0.38% fats, an "amorphous bitter substance" and an essential oil (Da Silva 1927). The essential oil [1.5% yield from root bark] contained 25.9% α-*pinene*, 7.8% β-*pinene*, 6.2% *camphor*, 6.6% camphene, 7.7% β-caryophyllene, 5.1% elixine, 9.2% α-humulene, 3.2% α-copaene and traces of many other constituents. The root bark has also yielded lupeol, methyl esters of arachidic, behenic and lignoceric acids, lipids, tertiary alkaloids and 0.4-0.5% of a mixture of compounds which is mostly the behenic acid ester of an α-sterol (Auterhoff & Pankow 1968; Bucek et al. 1987). A water/alcohol extract of the roots appeared to act on *dopamine* and/or *norepinephrine* receptors, based on animal studies (Siqueira et al. 1998). More information regarding this interesting plant may be found at http://www.rain-tree.com/muirapuama.htm.

Ptychopetalum olacoides is a loosely branched tree, sometimes slightly flexuose when young; branches terete, glabrous, dark; branchlets slightly longitudinally sulcate. Leaves obscurely green, pallid beneath, adult foliage subcoriaceous, glabrous and opaque on both sides, oblong-elliptic, long and narrowly acuminate, base acute, 9-11 x 2-2.5cm, with obtuse acumen 1-1.5cm long, midrib on upper side lightly sulcate, strongly prominent beneath, lateral nerves horizontal, becoming connected near margin, barely prominent; petiole 2-3cm long, subterete, canaliculate, subtended. Racemes alternate, flexuose, glabrous, sulcate, 1-3 from axils, 2-2.5cm long, 5-8-flowered; flower bud oblong-cylindric, 1-1.3cm long, 2mm thick; prophyll subtending the pedicel linear, reflexed; pedicel 2.5-3mm long; calyx small, 1mm high, subcoriaceous; petals externally glabrous, with white hairs inside near 2/3 of the way up, upper margin membranaceous, crenulate, inflexed, brownish; stamens numerous, but in some 10, with 5 short stamens alternating with petals, and with 5 short stamens opposite petals; anthers yellowish, filaments dorsally affixed. Fruit a drupe.

Habitat in n. Brazil, near Amazon River in insular forest; also in French Guiana (Fridericus & De Martius ed. 1965-1975).

PUERARIA

(Leguminosae/Fabaceae)

Pueraria lobata *(Willd.) Ohwi* **(P. argyi** *Lév. et Vaniot***; P. bodinieri** *Lév. et Vaniot***; P. caerulea** *Lév. et Vaniot***; P. chinensis** *(Benth.) Ohwi***; P. hirsuta** *(Thunb.) Matsum.***; P. koten** *Lév. et Vaniot***; P. pseudohirsuta** *Tang et Wang***; P. thunbergiana** *(Sieb. et Zucc.) Benth.***; P. triloba** *Makino***; Dolichos hirsutus** *Thunb.***; D. lobatus** *Willd.***; D. trilobus** *L.***; Neustanthus chinensis** *Benth.***; Pachyrhizus thunbergianus** *Sieb. et Zucc.***)** – kudzu vine, kudzu, kuzu, geh gen, ge gen

Pueraria mirifica *Airy-Shaw et Suvatabandhu* – kwao, kwao keur, paukse

Pueraria phaseoloides *(Roxb.) Benth.* **(Dolichos phaseoloides** *Roxb.***; D. viridis** *Buch.-Ham. ex Wall.***; Neustanthus phaseoloides** *(Roxb.) Benth.***; Phaseolus decurrens** *Graham***)** – tropical kudzu

Pueraria thomsonii *Benth.* **(P. lobata ssp. thomsonii** *(Benth.) Ohashi et Tateishi***; P. lobata var. thomsonii** *(Benth.) Maesen***; Pachyrhizus trilobus** *DC.***)** – kudzu, kuzu, geh gen, ge gen

In New Britain, Papua New Guinea, P. phaseoloides leaves are chewed as an intoxicant (Paijmans ed. 1976).

The edible roots of P. lobata and P. thomsonii are used in cooking as a starchy thickener. They are also used in TCM to treat poisoning from alcohol and other drugs (Reid 1995). As I write, an 'anti-hangover' drink containing 'kudzu' as the main ingredient has been on supermarket shelves in Australia for some years (pers. obs.). Medicinally, the roots of P. lobata and P. thomsonii have muscle relaxant, antipyretic, antihypertensive and antidysenteric actions (Tang & Eisenbrand 1992). In TCM [as 'geh gen'], they are considered neutral, sweet and bitter in energy, with an affinity for the stomach and spleen meridians. A decoction of 4-10g relieves fevers, headache, pains and tension in neck and shoulders, tones the skin, and treats urine retention, as well as acting as a nervine tonic, promoting a feeling of well-being (Reid 1995). American studies have shown that vine extracts may help suppress the craving for alcohol in alcoholics (Bremness 1994; Keung & Vallee 1997). P. mirifica roots are used in Thailand and Burma as a rejuvenative for the elderly; it is said that young people should not take it (Cain 1960; Chansakaow et al. 2000).

P. lobata root collected at the proper time [autumn & winter] has yielded 0.02-2% isoflavone derivatives [puerarin, daidzin, daidzein, daidzein-7,4'-diglucoside]; isoflavones [formononetin, 3'-OH-puerarin, 6"-O-D-xylosylpuerarin, 3'-MeO-puerarin, puerarin 4'-O-D-glucoside, and the 8-C-apiosyl-(1→6)-glucosides of diadzein and genistein]; aromatic glycosides [puerosides A & B]; the coumestan derivative puerarol; sapogenins [kudzusapogenols A-C, sophoradiol, cantoniensistriol, soyasapogenols A & B]; and 6,7-dimethoxycoumarin, 5-methylhydantoin, β-sitosterol, *choline* and *acetylcholine* (Tang & Eisenbrand 1992).

P. mirifica root has yielded the phenols deoxymiroestrol [a potent phytoestrogen, promotes growth of MCF-7 human breast cancer cells] and isomiroestrol; miroestrol itself was detected earlier, but appears to be an artefact of extraction. The roots has also yielded isoflavones and coumestans (Cain 1960; Chansakaow et al. 2000).

P. phaseoloides leaflets contain flavonoids such as genistein [MAOI (Hatano et al. 1991)], luteone, calopocarpin, phaseollidin and wighteone; stem contains vanillin, syringic acid, caffeic acid, ferulic acid, 4-OH-benzaldehyde, 4-OH-benzoic acid, 4-OH-3-MeO-benzoic acid and (*E*)-3-(4-OH-phenyl)-2-propenoic acid (International… 1994).

P. colletii and P. wallichii have been found to contain canavanine [see **Canavalia**] (Bell et al. 1978).

Pueraria phaseoloides is a robust, slender-stemmed twiner, climbing high, suffruticose, covered with spreading or ascending (sometimes reflexed) hairs, reddish, or lower surface of leaves subcanescent, +- vestite. Leaves alternate, entire or usually 3-foliolate, broadly rhomboid-ovate, apex acute, with long appressed and very short erect hairs adaxially, densely whitish sericeous-villous beneath, 2.5-12 x 1.5-9cm; stipule ovate-lanceolate, acuminate, striate, c.5mm long; stipel fairly long setaceous. Inflorescence elongate axillary racemes 10-20cm long, many-flowered, with swollen nodes; peduncles stout; bracteoles inconspicuous; flowers zygomorphic, to 8(-15)mm long; perianth biseriate; sepals usually 5, connate; calyx 4mm long, 4-5-lobed or -dentate, at summit triangular 2-

dentate, laterally small, at base quite long, acuminate tube long, otherwise short; standard petal deep mauve-pink, drying to bluish, obovate-orbiculate; keel fairly straight, or apex curved or rostrate, shortly beaked on top; wings falcate; auricles inflexed, usually appendiculate; stamens usually 10; anthers 2-locular, uniform, all fertile, usually dehiscing lengthwise. Ovary superior, subsessile, 1-locular; ovules many, anatropous; style simple, incurved above, filiform, beardless; stigma small, capitate. Legumes 5-9cm long, 3-4mm wide, narrow, compressed or subterete, linear, curved towards tip (not hook-like or oblique), pilose, glabrescent when ripe, 2-valved, dehiscent; seeds 10-15 per pod, small, transversely oblong, hilum lateral. Fl. May, Aug.-Dec.; fr. Aug.-Dec.

In damp areas, roadsides, riverside thickets, c.6-60m; native to tropical Asia, common in n. & e. India, Malacca, s. China; a weed in s. US, Caribbean, and parts of Africa, after being introduced as a cover crop (Adams 1972; Bentham 1867; Keung & Vallee 1997); also found in Papua New Guinea (Paijmans ed. 1976).

RANUNCULUS

(Ranunculaceae)

Ranunculus acris *L.* **(R. acer** *auct.***; R. acris var. latisectus** *Beck***)** – crowfoot, mao-ken, shui lang ['water lang']

Ranunculus quelpaertensis *(Léville) Nakai* **var. quelpaertensis (R. hakkodensi var. quelpaertensis** *(Lév.) Ohwi et Okuyama***; R. repens var. quelpaertensis** *H. Lév.***; R. ternatus var. quelpaertensis** *(Lév.) Ohwi***; R. vernyi var. quelpaertensis** *(Lév.) Nakai***)** – yama kitsune no botan, kitsune no botan

Ranunculus scleratus *L.* – marsh crowfoot

These 'buttercups' may have potential for use as inebriants, for those who like taking risks. R. acris is thought to be the plant referred to by Kohung and Li Shih-chen in 320AD – "...the Shui Lang [a kind of mao-ken], a plant with rounded leaves which grows along water and is eaten by crabs. It is poisonous to man and when eaten by mistake, it produces a maniacal delirium, appearing like a stroke and sometimes with blood-spitting. The remedy is to use liquorice" [see **Glycyrrhiza**]. Medicinally, it is applied only externally for inflammation and irritation. The Chinese term 'mao-ken' refers generically to Ranunculus spp. (Li 1978). The Cherokee use R. acris, R. abortivus and/or R. recurvatus to make a sedative tea; this is also used as a gargle for sore throats, and as a poultice for abscesses. The green parts are cooked and eaten as a vegetable (Hamel & Chiltoskey 1975). In Ladakh, India, R. sarmentosus ['chubansa'] is used as fodder for sheep, in order to promote their health (Bhattacharyya 1991).

R. scleratus causes contact-dermatitis and blistering. It was once used by some beggars in n. India for this property, to create or maintain skin sores in order to attract sympathy (Bhargava et al. 1965).

The irritating properties of Ranunculus spp. are lost on drying, and are due to an oily lactone, protoanemonin [5-methylene-2-oxodihydrofuran], which is formed from degradation of ranunculin [the β-D-glucoside of protoanemonin; the 'bound form' of protoanemonin in the plant], probably by the action of the enzyme β-glucosidase (Bai et al. 1996). Protoanemonin is converted to anemonin on drying. See **Clematis** for discussion of these compounds.

R. acris roots contain catechol phenols (Scott & Peterson 1979); aerial parts [harv. May, Canada] have yielded 2.75-2.87% ranunculin (Bai et al. 1996); flowers yielded volatile constituents, mostly trans-β-ocimene; pollen yielded protoanemonin (Bergstroem et al. 1995).

R. cymbalaria aerial parts [harv. Apr., May in Canada] have yielded 19.87-19.94% ranunculin (Bai et al. 1996).

R. quelpaertensis stems and leaves yielded the kava-lactone *yangonin* [see **Piper 2**], as well as protoanemonin, fumaric acid, palmitic acid, stearic acid, hexacontanol, stigmasterol and β-sitosterol (Shibata et al. 1972).

R. sceleratus has been shown to contain 7 *tryptamine*-derivatives, including 0.000016% *serotonin*; the other 6 were not identified. Also present were two compounds with anti-*serotonin* activity (Bhargava et al. 1965).

Ranunculus quelpaertensis is a nearly glabrate or sparsely hairy perennial herb; stems suberect to ascending, 15-80cm long, rather stout, branched; without stolons. Radical and lower cauline leaves petiolate, ternate, the leaflets petiolulate, broadly ovate to ovate-orbicular, 2-6cm long, 1.5-4cm wide, acute to subobtuse, 2-3-cleft, incised and acutely toothed, sessile. Flowers 8-12mm across, solitary or in terminal panicles, yellow, white to orange-red; sepals 3-5 or more, reflexed, ovate, concave, greenish; petals 5, free, ovate-oblong, slightly longer than sepals, flat, petaloid, with a nectariferous spot often covered by a small scale near base inside; stamens usually many, free; anthers introrse, longitudinally split; heads of carpels globose, 8-10mm across, receptacle short, short-pilose, carpels 1-locular; styles distinct; stigma terminal or oblique; ovules solitary, ascending. Achenes many, obovate, flat, glabrous, c.3.5mm long, with an indistinct ridge along the upper margin, the style prominent, distinctly recurved. Fl. Apr.-Jul.

Wet places in mountains; Kuriles, Korea, Japan, China, Ryukyus (Ohwi 1965).

RAUWOLFIA [Rauvolfia]

(Apocynaceae)

Rauwolfia caffra *Sond.* **(R. natalensis** *Sond.***)** – msesewe

Rauwolfia cubana *DC.*

Rauwolfia densiflora *Benth. ex Hook. f.*

Rauwolfia inebrians *K. Schum.*

Rauwolfia obliquinervis *Stapf*

Rauwolfia pentaphylla *Huber ex Ducke* **(R. duckei** *Markgr.***)**

Rauwolfia rosea *K. Schum.*

Rauwolfia sellowii *Muell. et Argov.*

Rauwolfia serpentina *(L.) Benth. ex Kurz* **(Ophioxylon majus** *Hassk.***; O. serpentinum** *L.***)** – Indian snakeroot, sarpaganda, sarpagandha, chandrika, chota-chand

Rauwolfia tetraphylla *L.* **(R. canescens** *L.***; R. heterophylla** *Roem. et Schult.***; R. hirsuta** *Jacq.***; R. tomentosa** *Jacq.***)** – American serpent wood, devil pepper, borrachera, boboro, cocotombo, matacoyote, veneno, guataco colorado, comida de culebra, viborilla, amatillo, chalchupa, yerba de San Jose

Rauwolfia verticillata *(Lour.) Baill.* **(R. brevistyla** *Tsiang***; R. cambodiana** *Pierre ex Pit.***; R. chinensis** *(Hance) Hemsl.***; R. latifrons** *Tsiang***; R. perakensis** *King et Gamble***; R. superaxillaris** *Li et Huang***; R. taiwanensis** *Tsiang***; R. yunnanensis** *Tsiang***; Cerbera chinensis** *Spreng.***; Dissolena verticillata** *Lour.***; Ophioxylon chinensis** *Hance***)** – luo fu mu

Rauwolfia viridis *Roem. et Schult.*

Rauwolfia vomitoria *Afzel.* **(R. senegambiae** *DC.***)** – African serpentwood, swizzle-stick tree, penpen

R. serpentina root has long been a valued herb in India and the Malay Peninsula, often used to treat venomous bites or stings [for which it is probably not very effective], and insanity; it has also been put to use as a hypnotic and uterine-contractant. Other traditional applications include uses as a vermifuge, and remedy for diarrhoea, dysentery, cholera and fever. R. serpentina and *reserpine* [one of the major active constituents] have more recently been used in the west for insomnia, high blood pressure, mental disorders, mania and epilepsy. *Reserpine* is now little-used in modern medicine due to the fact that some people may develop depression [sometimes suicidal] after prolonged use, as well as the strong likelihood of adverse reactions with other drugs, including psychiatric medications. The root may be made into a tea, or chewed. It is reputedly used by some saddhus to enter a tranquil state conducive to meditation, and was endorsed and used by Mahatma Gandhi. A number of Rauwolfia spp. are used medicinally in China for their roots, including R. verticillata, as antihypertensives, tranquillisers, and treatments for dermatitis and malnutrition (Blackwell 1990; Chopra et al. 1965; Emboden 1979a; Huang 1993; Morton 1977; Nadkarni 1976).

Rauwolfia spp. are widespread and much used in parts of Africa. In the Kilimanjaro region of Tanganyika, the Chaga add bark of R. caffra, roots or other parts of R. obliquinervis, and/or unspecified parts of R. inebrians to their **Musa**-based beer ['mbege'] to increase its potency [see *Methods of Ingestion*]. There is some incidence of death amongst people who regularly drink such fortified mbege. In Kenya, R. caffra stems are similarly added to beer. The fruits of R. caffra have caused a kind of mania followed by convulsions in dogs who have eaten them. Some species are used to kill dogs on purpose, such as R. mombasiana and R. obliquinervis. R. mombasiana roots have also been used by humans as a suicidal poison. Roots of R. rosea are aphrodisiac, and are used by the Shambala to treat venereal diseases. In Madagascar, aerial parts of R. capuroni and R. obtusiflora have been used as ordeal poisons (De Smet 1998; Watt & Breyer-Brandwijk 1962). Many species are emetic and purgative, and are used medicinally in cases where this is a virtue. Root of R. vomitoria is tonic and purgative, and the bark treats fever, indigestion and scabies (Watt & Breyer-Brandwijk 1962). It has been given in decoction to control tetanus spasms and suppress maniacal behaviour; it may also induce a deep sleep for several hours. It is sometimes given as an enema in the Ivory Coast for aphrodisiac effects, after evacuation (Morton 1977; Watt 1967). As 'sarna de perro', Rauwolfia spp. are used in Mexico to treat mental illness (Heffern 1974).

Rauwolfia spp. are known for their indole alkaloids, especially *reserpine*, which is a hypotensive sedative, hypnotic and tranquilliser [see *Chemical Index*]. Root barks yield greater alkaloid levels than the whole root, containing up to 90% of the total alkaloids.

R. caffra root bark has yielded *reserpine*, ajmaline [AChEI], *ajmalicine*, serpentine [AChEI, also inhibits histaminase, inhibits cancer cell replication], *rescinnamine*, raucaffrine, and traces of *yohimbine*, aricine, renoxidine and sarpagine (Beljanski & Beljanski 1982; Habib & Court 1973; Orgell 1963a; Sachdev et al. 1965); stem bark has yielded 0.025% alkaloids, consisting mostly of ajmaline, norajmaline, *ajmalicine* and ajmalicinine (De Smet 1998).

R. cubana stem bark has yielded tetrahydroalstonine, ajmaline, 16-epi-affinine, aricine, amerovolfine and amerovolficine (Martinez et al.

1989a).

R. densiflora roots and leaves showed sedative effects in rats (Weerakoon et al. 1998).

R. pentaphylla from Brazil has yielded up to 0.45% *reserpine* (Mors & Rizzini 1966).

R. sellowii, also from Brazil, yielded [from root bark] 1.2% ajmaline, 1.5% aricine, 0.0056% tetrahydroalstonine, 0.0009% *ajmalicine*, and small amounts of *reserpine* and tetraphyllicine. The alkaloid fraction containing *reserpine* was weakly sedative and hypotensive in animals; this activity was not exhibited by the other alkaloid fractions (Pakrashi et al. 1955).

R. serpentina root may contain 0.5-7.0% alkaloids – 0.05-0.2% *reserpine*, 0.02% rauwolfinine [hypertensive], 0.1% isoajmaline [hypotensive, causes drowsiness], 1.0% neoajmaline, *ajmalicine*, ajmalinine [hypotensive], ajmaline [stimulates respiration and intestinal movement, cardiac depressant], ajmalicidine, ajmalimine, ajmalinimine, serpentine [hypotensive, inhibits intestinal movement], serpentinine [hypotensive, purgative], rauwolfine, isorauwolfine, *rescinnamine*, *deserpidine*, chandrine [antiarrhythmic], rauwolscine [hypotensive, cardiovascular depressant, hypnotic], raujemidine [half as tranquillising as *reserpine*], rescinnamidine, sandwicoline, sandwicolidine, alstonine [antipsychotic-like effects in animals, inhibits replication of cancer cells], indobine, indobinine, isorauhimbine, N-methylraumadine, *papaverine*, raucaffricine, raumacline, renoxydine, reserpenediol, seredine and yohimbinine. Also present are oleoresins with hypnotic and sedative activity; steam distillation of the oleoresins yielded 0.22% essential oil, with serpoterpine the major constituent. The powdered root is taken orally as a tranquilliser in 100-150mg doses, twice daily; the effect is delayed in onset, and may be long-lasting [up to several weeks]. Do not take for extended periods. It can also have purgative actions, and supresses sexual desire and performance (Beljanski & Beljanski 1982; Bruneton 1995; Buckingham et al. ed. 1994; Chopra et al. 1965; Costa-Campos et al. 1998; Morton 1977; Siddiqui et al. 1987a, 1987b).

R. tetraphylla root has yielded 0.1-6.34% alkaloids – 0.04-0.17% *reserpine*, 0.1% rauwolscine, *deserpidine*, heterophylline, *ajmalicine*, ajmaline, alstonine, corynantheine, isoraunescine, raunescine, raujemidine, reserpiline, reserpinine, reserpoxydine, serpine, serpentine, *yohimbine* and β-*yohimbine*; and serposterol. Fruit is poisonous, and latex can cause blistering. The crude alkaloid extract of the root bark has sedative properties at 50mg/kg in rats – toxic effects only appeared at twice this dose (Madawala et al. 1994; Morton 1977). Leaf and fruits [both mature and immature] from Rockhampton, Queensland [Australia], harvested in December, tested strongly positive for alkaloids (Webb 1949).

R. verticillata root has yielded 1.31-2.7% alkaloids [0.04-0.107% *reserpine*] (Huang 1993).

R. viridis root bark and root wood have yielded (+)-ajmaline, (+)-quebrachidine, (-)-rauviridine, (+)-serpentine, (+)-sorpagine, (-)-*vobasine* and (+)-*yohimbine* (Martinez et al. 1989b).

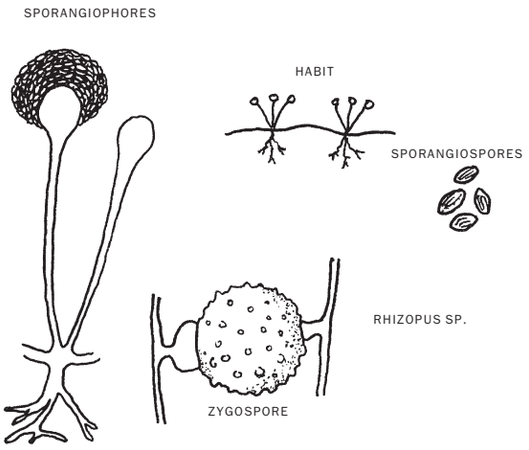
R. vomitoria leaves [harv. in Ghana] have yielded [w/w] 0.012% carapanaubine, 0.0005% isocarapanaubine, 0.006% aricine, 0.0015% reserpiline, 0.003% isoreserpiline, 0.0025% rauvoxine, 0.0008% rauvoxinine, 0.00175% tetrahydroalstonine, 0.0002% α-*yohimbine*, 0.00025% raucaffrinoline, 0.0002% perakine, 0.0002% peraksine, 0.00013% picrinine, 0.0001% normacusine B, 0.00028% akuammiline, 0.0003% deacetylakuammiline, 0.00013% desacetyldesformoakuammiline and 0.00008% geissoschizol (Amer & Court 1980). Root has yielded 0.79-10% alkaloids; 0.01-0.02% *reserpine*, ajmaline, alstonine, isoreserpiline, mitoridine, purpeline, rauvanine, rauvomitine, rescidine, reserpiline, *rescinnamine*, sarpagine, seredamine, serpentenine and *yohimbine*. Large doses may cause paralysis and death (Bruneton 1995; Morton 1977).

Rauwolfia serpentina is an erect, glabrous shrub, 30-60cm(-1m) high; roots tortuous, often yellowish, cross-section showing a substantial proportion of finely radiated wood, cortex thin. Leaves whorled, in cymes of 3-4, 8-18cm long, thin, lanceolate or oblanceolate, acute or acuminate, tapering gradually into the petiole; peduncles alternating with terminal leaves, becoming lateral. Flowers white or pinkish; peduncles 5-13cm long; pedicels red; calyx red, 5-lobed, lobes 2.5mm long, lanceolate, eglandular within; corolla salver-shaped, about 1.2cm long, tube cylindric, slender, inflated a little above the middle around the stamens, throat usually hairy within, lobes much shorter than tube, obtuse, overlapping to the left; stamens included. Disc cupular or annular; carpels 2, distinct or connate; ovules 2 in each carpel, collateral. Ripe carpels drupaceous, single or didymous and more or less connate, c.6mm diameter, purplish-black when ripe, usually 1-seeded. Seeds ovoid; albumen fleshy.

Native to India, found up to 1219m; Sub-Himalayan tracts, plains near foothills from Sirhind east to Assam; also in Konkan, n. Kanara, s. Mahratta Country, w. & e. Ghats, Bihar, n. & c. Bengal (Bruneton 1995; Chopra et al 1965). Also in Malaysia and Indonesia; cultivated in India and the Philippines (Chevallier 1996).

RHIZOPUS

(Mucoraceae)



Rhizopus nigricans *Ehrenb.* **(R. stolonifer** *(Ehrenb. ex Fr.) Vuill.***)** – soft rot, ear rot

This is a mould found on some vegetables [sweet potato (see **Ipomoea**), carrots (**Daucus**), beans, onions, lettuce (**Lactuca**), strawberries, **Citrus** fruits, pears, peaches (see **Prunus**) and avocado], infestation being noticed by the foul-smelling, watery liquid that exudes from the fruit or vegetable, which turns soft (Hocking & Pitt 1996). 'Tempeh' products are prepared using Rhizopus spp., especially R. oryzae [see also **Aspergillus**] (Kinosita & Shikata 1965), which is very similar to R. nigricans. These moulds may also be found in soil (Gilman 1957).

R. nigricans tested strongly positive for alkaloids; these have been shown to include the ergot alkaloids [see **Claviceps**] *agroclavine*, ergosine and ergosinine (El-Refai et al. 1970; Sallam et al. 1969; Spilsbury & Wilkinson 1961). Rhizopterin, fumaric acid, androstane-3,6,17-diol, 11,17,21-trihydroxypregnane-3,20-diol and 3,11-dihydroxyandrostan-17-one have also been found (Buckingham et al. ed. 1994). Some of the compounds known to be produced by R. nigricans are powerful toxins (Kinosita & Shikata 1965), and the fungus should not be directly consumed. R. arrhizus has also tested positive for alkaloids, mostly fumigaclavine B (Spilsbury & Wilkinson 1961).

Rhizopus nigricans has mycelium of 2 kinds – one submerged in the substratum, and the other aerial, arching filaments or stolons; stolons creeping, recurving to the substrate in the form of arachnoid hyphae, strongly raised and distant from the substrate, implanted at each node by means of rhizoids; internodes often to 1-3cm, hyphae +- branched; sporangiophores rarely single, united in groups of 3-5 or more, 0.4-4mm tall, 24-42µ diam., summit of sporangiophore enlarged into an apophysis with columella inserted above the point where the spherical bend attaches to the filament, apophysis broad and cuneiform; sporangia white at first, bluish-black at maturity, hemispheric, 100-350µ; columellae broad, hemispheric, depressed, 70(-250)µ diam. x 90(-320)µ tall, forming after dehiscence by collapse; spores unequal, irregular round or oval, angular, striate, 9-12µ long x 7.5-8µ diam., grey-blue; zygospores formed in substratum and on stolons, round or oval, 16-220µ diam.; exine brown-black, verrucose; suspensors straight, swollen, usually unequal, azygospores present.

Found in soil; recorded from northern hemisphere (Gilman 1957).

RHUS

(Anacardiaceae)

Rhus aromatica *Aiton* – oak-leaf sumac [also spelt 'sumach'], fragrant sumac, skunkbrush sumac, skunkbush

Rhus copallina *L.* **(Schmaltzia copallina** *(L.) Small***; Toxicodendron copallinum** *(L.) Kuntze***)** – copal sumach, dwarf sumac, winged sumac, flameleaf sumac, shining sumach, Texas sumac

Rhus glabra *L.* **(Schmaltzia glabra** *(L.) Small***; Toxicodendron glabrum** *(L.) Kuntze***)** – red sumac, smooth sumac, dwarf sumac, upland sumac, mountain sumac, vinegar tree, maw-ko-la ['tobacco mixture'], no'-anio-ni-mai'-ki ['mixing ingredient'], haz-ni-hu ['water fruit bush'], chanzi ['yellow wood'], nuppikt ['sour top'], pekwana' nomishi, dimeyov

Rhus radicans *L.* **(Toxicodendron radicans** *(L.) Kuntze***)** – zumaque, poison ivy

Rhus trilobata *Nutt. ex Torr. et A. Gray* **(R. aromatica ssp. trilobata** *(Nutt. ex Torr. et Gray) W.A. Weber***; R. aromatica var. trilobata** *(Nutt. ex Torr. et Gray) Gray***; Schmaltzia trilobata** *(Nutt. ex Torr. et Gray) Small***)** – aromatic sumac, ta-n-pai-a

Rhus typhina *L.* **(R. hirta** *(L.) Sudw.***; Toxicodendron typhinum** *(L.) Kuntze***)** – stag's horn sumach, velvet sumac, Virginian sumach, vinegar sumac, vinegar tree

The leaves, and sometimes the bark of R. glabra are used by some N. American tribes [such as the Omaha, Zuni and Kiowas] as a smoking herb, to be used alone or mixed with tobacco [see **Nicotiana**] or other herbs. The Cheyenne smoke R. aromatica with tobacco, 'dogwood' [see **Cornus**] and 'bearberry' [see **Arctostaphylos**]. The Kiowa mix the leaves of R. glabra with tobacco to add to the purifying effects of the tobacco; the mixture is smoked at the beginning of a peyote [see **Lophophora**] ceremony. It was noted by R.E. Schultes that "this blending of sumac and tobacco is so well liked by men and women generally that it is common in everyday social smoking". The Cheyenne believe R. glabra was given to them by the great spirit. R. glabra also has many medicinal uses. The Cherokee chewed the berries to stop bedwetting and vomiting; the berries also make a red-black dye. The astringent root yields a yellow dye, and is used to treat urine retention and painful urination. Leaves and berries may be applied externally to wounds and irritations. The Ozarks use the twigs as chew-sticks, to prevent tooth-decay. The Comanche and Kiowa also smoke R. trilobata with or without tobacco. In the vicinity of Missouri and the Mississippi, R. copallina leaves have been smoked as a tobacco substitute, and in Virginia, R. typhina leaves are similarly used. R. aromatica fruits were chewed by the Cheyenne as an analgesic for toothache; the Kiowa ate them to treat flu and stomach ache. The Comanche chewed the bark and swallowed the juice to treat colds (Cooke 1860; Hamel & Chiltoskey 1975; Kindscher 1992; Schultes 1937a; Winter 1998). Resin from Rhus spp. may also be used as 'copal' incense [eg. see Bursera and Protium in *Endnotes*] (Case et al. 2003).

In Tanganyika, the Shambala use the root of R. natalensis to relieve fits in children (Watt 1967), and in Basutoland, R. erosa is used as an ash added to snuffs, often based on tobacco (Watt & Breyer-Brandwijk 1962).

Care should be taken not to confuse any sumac with poisonous species, now generally transferred to the genus Toxicodendron. Representatives include 'eastern poison oak' [T. toxicarium], 'western poison oak' [T. diversilobum], 'poison ivy' [R. radicans] and 'poison sumac' [T. vernix]. They have whitish fruits in axillary pendulous clusters; the 'good' sumacs have red fruits. The toxic species release an oily sap [most abundant in spring and summer] when bruised or even brushed past lightly; this sap is highly irritating and results in severe dermatitis, as does the fruit when eaten. The sap may contain toxins such as urushiol and toxicodendrol. Inhaling smoke from the burning plant may apparently result in the same symptoms of toxicity (Foster & Caras 1994), though in Mexico, R. radicans is used with caution when dry as a 'stimulant narcotic'. Its toxic properties are believed by locals to exist mainly in the fresh plant (Heffern 1974).

Although generally safe in low doses, high doses of R. glabra tincture [30-120 drops] have produced toxic reactions such as gastric pain, headache, ulceration of the mouth, diarrhoea, water retention and night sweats. R. glabra caused an unintentional intoxication of sorts in one 19th century plant enthusiast. After manual contact with fresh branches of the plant [being used to swat mosquitoes] and eating some of the berries, vivid dreams of flying through the air were experienced over the next three nights (Millspaugh 1892). When smoked, R. glabra induces a mild and pleasant alteration of consciousness that is difficult to adequately describe. The lady who sold me the sample that I tried has since claimed to a friend of mine that it "opens the third eye" (Baill pers. comm.), yet such extravagant claims abound in many naïve New Age circles.

R. glabra contains the flavonoid fustin [antibacterial, antiviral; inhibits NADH-oxidase and succinoxidase], methylgallate, gallic acid, gallotannic acid, 4-MeO-3,5-dihydroxybenzoic acid, calcium bimalate, resins, sugars, starch and a gum; leaves also yield 15-27% tannic acid. The plant has antibacterial properties (Buckingham et al. ed. 1994; Harborne & Baxter ed. 1993; Kindscher 1992; Saxena et al. 1994) and inhibits human plasma AChE (Orgell 1963b).

Rhus glabra is a sparsely-branched shrub to 6m tall; younger branches and petioles glabrous and somewhat glaucous. Leaves alternate, pinnately compound; leaflets 11-31, lanceolate to narrowly oblong, 5-10cm long, apex acuminate, margin commonly serrate, upperside dark green and shiny, leaflet paler beneath; rachis of leaf not winged. Flowers small, in large terminal panicles to c.20cm long, sometimes male and female flowers separate; calyx 5-lobed; petals 5, greenish; stamens 5, inserted beneath a disc surrounding the ovary; pistil 1, with 3 carpels. Ovary 1-celled, sessile on disc, with single ovule; styles 3, terminal; ovule basal, inverted from apex of its funiculus. Fruit a bright red drupe, densely covered with minute obovoid hairs c.0.2mm long, rounded, 3.5-4.5mm diam. Fl. May-Jun.; fr. Aug.-Sep.

Abundant in upland soil, old fields, roadsides, wood margins; New England to British Colombia, south to Florida, Texas and Mexico (Gleason 1952).

RHYNCHOSIA

(Leguminosae/Fabaceae)

Rhynchosia longiracemosa *Martens et Galeotti* **(Dolicholus longiracemosus** *(Martens et Galeotti) Rose***)** – peyote

Rhynchosia phaseoloides *(Sw.) DC.* **(R. bicolor** *Micheli***; R. erythrinoides** *Cham. et Schltdl.***; R. phaseoloides var. precatoria** *(DC.) Griseb.***; R. precatoria** *DC.***; R. pyramidalis** *(Lamarck) Urban***; Dolicholus phaseoloides** *(Sw.) Kuntze***; D. pyramidalis** *(Lam.) Britton et P. Wilson***; D. vailiae** *Rose***; Glycine phaseoloides** *Sw.***)** – piule, bejuco culebra, coralito, favinha, huayruru-huasca, kokriki, mulungu, olho de onca, pega-palo ['virility vine'], guatabe, pimande, oja de cangrejo, atecuxtli, crab-eye

What are believed to be seeds of a Rhynchosia sp. are depicted in the Mexican Tepantitla fresco [dating from approximately 300-400AD], falling from the hand of Tlaloc, the Aztec rain god. The context of their representation has caused some to suggest that they may have visionary properties. Today in Oaxaca, the seeds are known as 'piule', a word used also to refer to visionary **Psilocybe** mushrooms, and some species of morning glory [see **Ipomoea** and **Turbina**] (Emboden 1979a; Ott 1993; Schultes 1969c; Schultes & Hofmann 1980, 1992). R. longiracemosa is known to be 'narcotic', and is referred to in some areas of Mexico as 'peyote' [see **Lophophora**], further alluding to psychotropic properties (Schultes 1937a, 1937b). Its seeds are recorded as having been used magically. R. phaseoloides seeds are known to be 'narcotic' and toxic, as well as causing 'insanity'. Accordingly, they have been powdered and given to the unsuspecting to cause harm. In northern Mexico, the plant is used as a topical analgesic. In the Dominican Republic, a stem decoction or alcohol extract is used as an aphrodisiac for males. It is reputed to increase sexual desire and strengthen performance, though animal studies have so far not confirmed these properties (Diaz 1979; Farnsworth et al. 1967; Jiu 1966). As R. precatoria, it has been claimed that the seeds are used in some areas of Mexico to prepare a 'sinicuichi' beverage [see **Heimia**] (Blomster 1964a).

Rhynchosia sp. seeds have shown a curare-like action in animals similar to, but weaker than that of **Erythrina** spp. (Diaz 1979).

R. phaseoloides seed has yielded an un-named alkaloid [Rhynchosia alkaloid A] and ethyl gallate; the foliage contains the flavonoids cajanin, genistein [MAOI (Hatano et al. 1991)] and 2'-OH-genistein (International… 1994; Ristic & Thomas 1962). Stems were estimated to contain 0.19% crude alkaloids, which were not identified, as well as saponins, tannins, phenols and inorganic acids; flavonoids appeared to be absent. The stem extract acted as a CNS-depressant in mice. An extract of the seeds showed some curare-like activity in animals (Farnsworth et al. 1967).

R. suaveolens leaves have yielded *mangiferin*, isomangiferin, luteolin, orientin, isoorientin, vitexin, isovitexin, vicenin-2 and (+)-pinitol (Adinarayana & Ramachandraiah 1985).

R. australis [leaf], R. cunninghamii [leaf, stem, seed] and R. minima [leaf, stem], all growing in Queensland, Australia, gave negative results in alkaloid screening (CSIRO 1990).

Rhynchosia phaseoloides is a perennial climbing herbaceous vine; stems to 6m or more from a woody base, velvety-pubescent throughout, subterete or ribbon-like. Leaves pinnately trifoliate; leaflets broadly ovate to rhomboid, obtuse to shortly acuminate, somewhat attenuate, 5-10(-13) x (1.5-)3-7(-8)cm, velvety-puberulent but green on both sides, subglabrous adaxially, tomentellous beneath, bearing small resinous glands at least beneath; petioles stoutish, 1-5cm long; stipules small, very early deciduous; stipels absent. Flowers in axillary racemes 10-30cm long or less; bracts caducous, linear-lanceolate to ovate-lanceolate, 2-3.5mm long, early deciduous; pedicels 2-3mm long; calyx 5mm long, campanulate, 4-5-toothed, puberulent, tube 1.5-2mm long, lower teeth linear-subulate, 4-5mm long, upper ones about ½ as long; corolla 7-10mm long; standard yellow streaked with dark crimson, obovate or orbicular, erect or reflexed, puberulent and resinous-dotted on back; wings narrow, ovate; keel green, falcately curved upwards, obtuse; stamens diadelphous; anthers alike, 2-locular. Ovary superior, subsessile, 1-locular; ovules 2; style simple, filiform, glabrous. Pods oblong, compressed, constricted between seeds, 2-2.5cm x 8-15mm, puberulent, 2-valved, dehiscent; seeds 1-2, compressed-subglobose, 5-6mm diam., bright red around hilum, shining black on upper part, proportions of black and red areas variable. Can flower all year round, depending on location.

Climbing over shrubs, in thickets and woodland margins, 300-1200m; central Sonora [Sonoran Desert] to San Luis Potosi and tropical Central and South America, including Caribbean (Adams 1972; Shreve & Wiggins 1964).

Propagate by nicking the seed, and sowing in damp peat moss with bottom heat. Transplant into rich, well-drained soil. Grow outdoors in warm-hot climates; cut back and bring indoors for winter in colder climates (Grubber 1973).

ROEMERIA

(Papaveraceae)

Roemeria refracta *(Stev.) DC.* **(R. rhoeadiflora** *Boiss.***; Glaucium refracta** *Stev.***; Papaver refractum** *(DC.) K.F. Ginther***)**

This Eurasian poppy does not seem to have any traditional uses – however, its chemistry warrants our interest, being the only poppy so far known to contain *ephedrine* and pseudo-*ephedrine*.

R. refracta has yielded 0.016% l-*ephedrine* and 0.024% d-pseudo-*ephedrine* (Konovalova et al. 1940), as well as a great variety of isoquinoline alkaloids – including roemerine [0.01%], roemeramine, roemerenine, remrefidine, remrefine, roemeroline, roefractine [0.0002%], roemecarine [0.0003%], armepavine, pseudolaudanine [0.0002%], eschscholtzinone, reframidine, reframine, reframoline, norefamidine, refractamine, amurine [0.003%; tranquilliser, analgesic, expectorant], noramurine and aporheine. Flavinantine has also been found in the plant (Buckingham et al. ed. 1994; Gözler 1988, 1990; Gözler et al. 1990; Guinaudeau et al. 1975; Harborne & Baxter ed. 1993; Konovalova et al. 1939).

R. hybrida has yielded two new proaporphine-*tryptamine* alkaloids, (-)-roehybramine-β-N-oxide and (-)-roehybridine-α-N-oxide (Günes & Gözler 2001).

Roemeria refracta is a slender, annual herb with foetid yellow sap; stems up to 50cm or more tall. Leaves usually alternate, 2-3-pinnatisect with narrow, +- linear segments, the lower petiolate, the upper sessile, segments terminated by bristles. Flowers actinomorphic, showy, solitary on short peduncles; buds narrowly pyriform, apex obtuse, c.1cm long; sepals 2, separate, soon deciduous; petals 4, free, undivided; filaments of the stamens dilated. Ovary linear-cylindrical, superior; stigmas stalked, 3-4, not borne on a disc, capitate. Fruit a siliquiform capsule, linear, cylindrical, more than 10 times as long as wide, opening by 3-4 valves, unilocular, glabrous except for 4 setae which extend above and between the stigma lobes, attenuate at apex; seeds numerous, unappendaged. Fl. Jun.

Turkey, Iran, Afghanistan, w. Pakistan; reported as a weed in Utah and California (Bailey & Bailey 1976; Davis ed. 1965).

SALVIA

(Labiatae/Lamiaceae)

Salvia amarissima *Orteg.*
Salvia apiana *Jeps* – white sage, sage brush
Salvia argentea *L.*
Salvia carnosa *Dougl. ex Benth.*
Salvia chinensis *Benth.* **(S. japonica var. chinensis** *(Benth.) E. Peter***; S. japonica var. integrifolia** *Franch. et Sav.***; S. prenia; S. tashiroi** *Hayata***)** – Chinese sage, shih-chien-chuan, shi-jian-chuan, hsiao-tan-shen
Salvia coccinea *Jussieu ex Murray* **(S. coccinea** *Buc'hoz ex Etl.***; S. galeottii** *Martins***; S. glaucescens** *Pohl.***; S. pseudococcinea** *Jacq.***)** – tropical sage
Salvia divinorum *Epling et Jativa* – diviner's sage, seer's sage, hierba Maria, ska Pastora, hojas de la Pastora, ska Maria Pastora
Salvia elegans *Müll.-Arg.* – pineapple sage
Salvia farinacea *Benth.* – mealy sage
Salvia greggii *A. Gray*
Salvia guaranitica *St.Hilaire ex Benth.* **(S. caerulea** *Moc. et Sessé ex Benth.***)** – anise-scented sage
Salvia haematodes *Wall.* **(S. pratensis** *L.***)** – meadow clary, meadow sage, red sage, behen, lal-bahamana, hexgimaie
Salvia 'indigo spires'
Salvia leucantha *Cavanilles* – Mexican bush sage
Salvia lyrata *L.* – lyre-leaf sage, cancer weed
Salvia mellisodora *Lagasca* – grape-scented sage
Salvia miltiorrhiza *Bunge* **(S. yunnanensis** *C.H. Wright***)** – dan shen, tan shen, tan sêng, scarlet sêng, red rooted sage
Salvia officinalis *L.* – common sage, garden sage, Dalmatian sage, herba sacra
Salvia persepolitana *L.*
Salvia plebeia *R. Br.* – kokaburadi, bhui-tulsi, shati, nirvisham, chin-khing-kai, Australian sage
Salvia purpurea *Cavanilles*
Salvia sclarea *L.* – clary sage, clear eye
Salvia sonomensis *Greene* – creeping sage, Sonoma sage
Salvia splendens *Sell. ex Roem. et Schultes* – scarlet sage, splendid salvia
Salvia x superba *Stapf.*
Salvia triloba *L. f.* **(S. fruticosa** *Mill.***)** – three-lobed sage, Turkish sage, Dalmatian sage, Greek sage, faksomilo
Salvia tubiflora *Smith* **(S. biflora** *Ruiz et Pav.***)** – nucchchu
Salvia uliginosa *Bentham* – bog-marsh sage, bog sage
Salvia spp. – sage

Common sage [S. officinalis] is well known for its culinary uses, though it has long been said to give longevity; its genus name comes from the Latin 'salvere', meaning 'to save'. It is also renowned as a nerve tonic, said to restore failing memory, quicken the senses and promote wisdom. The Romans treated it with great reverence and gathered it with respect and ritual in mind, wearing a white tunic and bare feet, after washing and offering food sacrifices to the plant. In TCM, it is used as a yin tonic to calm and simultaneously stimulate the nervous system; it also acts as a muscle relaxant. The Cherokee used it alternately with S. lyrata to treat nervous debility, as well as other common disorders. In s. Italy, S. officinalis is sometimes smoked with **Datura** stramonium to treat asthma. It is useful in treating menstrual irregularities due to its content of oestrogen precursors. The herb is astringent, antiseptic, tonic, digestive and intoxicating – it also treats asthma, sore throats and intestinal gas (Bremness 1988, 1994; Chevallier 1996; Chiej 1984; Cunningham 1994; Hamel & Chiltoskey 1975; Lawless 1994; Ody 1993; Ott 1993; Simonetti 1990; Tierra 1988). The herb has been described as having a 'narcotic' action (Pammel 1911). In commerce, S. triloba is frequently substituted for S. officinalis. In Crete and other parts of Greece it is popular as a tea, made using a shoot 15-20cm long per cup. It is reputed to give "a feeling of well-being" and to act as a blood purifier (Tucker 2004; Tucker et al. 1980).

S. sclarea ['clary sage'] seeds were once used to treat eye problems, and powdered and mixed with wine they were said to help incite lust. The Germans used it in wine, and the English used it around the 16th century to make their beer more intoxicating. Clary sage is also an excellent nerve tonic, and is much used in aromatherapy, where it is said to be aphrodisiac, euphoric, sedative, relaxing, rejuvenating and inspiring; its use seems to inspire vivid dreams. If taken with alcohol, it can cause nausea or nightmares. In herbal medicine, it is used to treat period pain, menstrual disorders, menopausal complaints, gas, indigestion and asthma (Bremness 1994; Chevallier 1996; Cooke 1860; Lawless 1994). The psychotropic properties of S. sclarea are also felt when the dried foliage or flower buds are smoked; S. sclarea var. 'Turkestanica' is also active when smoked (pers. obs.). One person who took a bath with clary sage essential oil, having also just consumed a small vodka, experienced open-eye hallucinations, though otherwise, the mental effects were no stronger than the essential oil alone (theobromus pers. comm.).

S. miltiorrhiza is valued in TCM for its roots, which act primarily as a heart and circulation tonic. It clears blood congestion and treats angina, palpitations, menstrual problems, impact injuries, liver disease and inflammations. It is an antioxidant, mild vasodilator, hypotensive, analgesic,

antibacterial and sedative, and treats insomnia and nervous exhaustion or irritability (Bone 1996; Bremness 1994; Bruneton 1995; Chevallier 1996; Hsu et al. 1986; Huang 1993). It should not be taken with warfarin, as it interferes with the elimination of that toxic coumarin (Fugh-Berman 2000).

S. apiana, 'white sage', is used as a smudging plant by native N. Americans in s. California, due to the purifying properties of its smoke. However, it often seems to be confused in the literature with **Artemisia** ludoviciana, which is also called white sage, and used in the same way. It is unfortunate that the 'true' sage of the two plants is the one that is usually overlooked! S. apiana leaves are psychotropic when smoked (pers. comms.).

S. carnosa is smoked or drunk as a stimulant, and to treat epilepsy and faintness by the Hopi. S. haematodes root is used in Indian folk medicine as a tonic aphrodisiac, and to prevent premature ejaculation, as well as to promote erection, properties which have been confirmed in rats. It also acts as a *diazepam*-like anxiolytic, cerebral tonic and cardiotonic. As S. pratensis, it has been claimed to be 'narcotic', as has the Mexican S. amarissima. S. persepolitana may not be psychoactive, but was once proposed to be the identity of 'haoma' [see **Peganum**]. S. sonomensis is a mild stimulant when smoked (Heffern 1974; Islam et al. 1991; Nadkarni 1976; Ott 1993; Pammel 1911; Pendell 1995), and in S. Africa, S. chamelaeagnea leaf is infused to relieve convulsions (Watt 1967). The Soto of Africa smoke S. repens, S. runcinata and S. stenophylla with their tobacco [see **Nicotiana**], and burn them to cleanse a hut after a sickness (Watt & Breyer-Brandwijk 1932). In Basutoland, Salvia spp. are used as ash with snuffing tobacco (Watt & Breyer-Brandwijk 1962).

Interestingly, Moroccan legends tell of Sidi Hidi, who lived at an uncertain time in history, and was said to have introduced 'kif' [**Cannabis**] to Morocco. It has been claimed, however, by an informant from the small town named after him [as it is believed to have been his final resting place], Sidi Hidi did not smoke kif, but a mixture of two local sages – a similar leaf is engraved on the stem of many sebsi pipes [long, thin Moroccan pipes for smoking kif] of the region (Clarke 1998). Obscurely, the Nahuatl of the Sierra de Puebla of Mexico use an unidentified Salvia sp., 'xiwit', which is smoked, and an infusion drunk, before going to sleep in order to experience vivid and prophetic dreams (Diaz 1979; Mayagoitia et al. 1986). S. mellisodora has been claimed to be sacred to the Tarahumara (Gruber 1997), however this was an error resulting from a miscommunication (Glass pers. comm.). S. tubiflora flowers are often depicted on wooden cups and pottery from Incan times, in Peru. The Incans used the flowers and a flower infusion in rituals to placate the forces responsible for causing earthquakes, a practice still observed recently in Cuzco (Towle 1961).

S. splendens has been found by some humans to be a mild antidepressant and anxiolytic with some persistent effects lasting for up to several days [at least for some of my correspondents]. More immediate effects when smoked or taken sublingually may include relaxation, slight heightening of visual perception, and a mild dissociative state. Many horticultural varieties of this herb exist, and the most effective of several types investigated was the 'Blaze of Fire' cultivar (Christian & Simon pers. comm.). The 'Sizzler' varieties have been observed to be completely inactive by some; these varieties are very common in horticulture, at least in Australia (Torsten pers. comm.). Still, some believe this species is not active at all. Following this interest, and the confusion between people who said the species was active and others who said they didn't notice any effects, Daniel Siebert conducted a small-scale double-blind experiment with 31 volunteers to determine whether S. splendens leaf was psychoactive at all. Viola odorata leaf was the chosen placebo, and the S. splendens samples used had been claimed to be active by others who had previously noted some effects from consuming the leaf. The results indicated that S. splendens performed similarly to the placebo, and therefore was considered non-psychoactive, or at least possessing some kind of very mild activity that was not detected by this study (Siebert1999). On the other hand, I have given active strains to friends to smoke, without telling them what it would do or indeed if it would do anything at all, just asking for them to describe any reaction that occurred - and these people described similar effects to those I had experienced from my own experiments. Also, the genus Viola may not be entirely devoid of psychoactivity, either [see *Endnotes*]. There still seems to be more to learn about the pharmacology of S. splendens and its many horticultural variants, and it may be that effects of active strains are only noticed by some people at some times, depending on their state of physiological balance. Adding to the confusion of such matters of subjective pharmacology, I know someone who smoked **Cannabis** for many years socially, before ever noticing any effects from it, and from then on, he got stoned every time he smoked it (pers. obs.).

S. uliginosa was found to be weakly psychoactive, similar to weak **Cannabis** leaf, in the form of a dried alcohol extract of the leaf [see *Producing Plant Drugs*], which was smoked through a water pipe. Also active by this method or by simply smoking the leaves and/or flowers were S. 'indigo spires' [a spontaneous cross between S. farinacea and S. longispicata], which roughly 1 minute after smoking produced a relaxing effect with mild dissociation, as did S. 'Huntington's red', S. involucrata, S. leucantha, S. purpurea, S. coccinea, S. elegans, S. guaranitica and S. haematodes (pers. obs.). Others have found S. argentea, S. chinensis [as S. prenia], S. farinacea, S. greggii, S. lyrata and S. superba to also be similarly psychoactive (friendly 1997; friendly pers. comm.). Of these, the whole plant of S. chinensis is used in TCM to treat asthma due to phlegm congestion, hepatitis, scrofula, carbuncles, dysphagia and leucorrhoea (Hsu et al. 1986). S. coccinea has been implicated in causing abortion in pregnant cows in Queensland, Australia (Webb 1948).

S. plebeia, of Australia and Malaysia, has been claimed to possess similar properties to S. divinorum [see below] (pers. comm.), though it is unclear how much broad generalisation or assumption was involved in this observation. I believe the person who passed on this information had probably not actually tried S. divinorum. In Australia, it is suspected of being poisonous to stock animals (Hurst 1942). In India, the seeds of S. plebeia are taken to treat seminal weakness and to "promote sexual powers". S. pumila apparently shares the same uses (Nadkarni 1976).

S. divinorum of Oaxaca, Mexico, is far removed from any of these sages in its effects. Medicinally, several leaves may be infused or applied as a poultice. They act as a tonic, treating diarrhoea, excessive urination, anaemia, headache and rheumatism. It has been proposed to represent the unidentified Aztec entheogen 'pipiltzintzintli' ['most noble prince' or 'venerable little children'], but it is now considered to be very unlikely that they could have been the same plant. However, besides the known traditional medicinal uses of S. divinorum in low doses, the herb is also traditionally employed by the Mazatec as a sacred shamanic ally. This is usually when **Psilocybe** mushrooms are out of season, or in early stages of shamanic tuition. Its use is not usually discussed casually or with strangers, and some of its names show an association with the Virgin Mary, most likely a remnant of earlier times when the plant was hidden and linked with Catholicism to avoid the wrath of the Spanish conquistadores. The plant is gathered with great respect, and its location kept secret. The leaves are usually taken in pairs when fresh – this may be from 20-80 pairs, with lower doses [4-6 pairs] reserved for non-psychotropic medicinal use. They may be wrapped in other leaves to keep them fresh – they are said to lose their strength on drying, but this is not true. After cleansing in incense smoke they are crushed on a metate and the juice drunk neat, or infused into water before drinking. A potent drink is said to have a good head of froth, which may signify an effective emulsion of the active compounds with the water [as they are not generally water-soluble] and ensure better absorption [as the non-emulsified compounds do not appear to be absorbed well through the stomach]. Alternately, and for a stronger effect using less plant matter, they are chewed as a whole quid kept in the mouth, without swallowing the saliva. The plant and its juices are very bitter, though today some 'palatable' strains [which are less bitter] have been cloned and made available commercially. The plant is taken shamanically in darkness and quiet, as light and sound distractions can greatly dissipate the intensity of the experience [this is not so with enriched smoking preparations, or vapourised *salvinorin A* – see below] (Diaz 1979; Ott 1993, 1996a; Siebert 1994; Valdés 1994; Valdés et al. 1983, 1987a; Wasson 1962, 1963).

More recently, Mexican youths have been observed smoking the dried leaves for a mild **Cannabis**-like effect. With continued use, however, this would be expected to give way to far stronger effects than anything comparable with **Cannabis**! For many years westerners investigating the effects of this plant believed it to be inactive or so weak, inconsistent and bad-tasting as to be barely worth pursuing, and attempts at isolating an active compound from the leaves had proven fruitless. The former was largely due to inappropriate methods of ingestion; the latter to the fact that researchers were searching for an alkaloid, as all previously known plant 'hallucinogens' contained alkaloids as their major active components [and S. divinorum does not]. It has recently been found that a simple denatured alcohol extract, evaporated onto ¼ the amount of the original leaf mass [see *Producing Plant Drugs*] and smoked in one deep inhalation, held in the lungs for as long as possible, is strongly active, so much so that many have described it as being 'too strong'. The dried leaf itself can also be quite strongly effective, provided the smoke is properly inhaled and the material is potent.

Effects at low dosage were compared by R.G. Wasson to the early stages of a **Psilocybe** mushroom experience. There may be vivid colour hallucinations, mild perceptual distortion and activation of thought processes [even lower doses may be milder and vaguely **Cannabis**-like – see above]. Some may dispute any similarity to **Psilocybe** – in truth, the activity of this plant is quite unique, especially at higher doses. Such doses can be intensely hallucinogenic, with the user losing motor co-ordination and awareness of physical surroundings, and entering extremely bizarre states of subjective reality. Effects last 1-2 hours when taken orally, or 20-30 minutes when smoked, though residual effects [usually pleasant] may linger. The most intense part of the experience is usually much shorter [ie. around 5 minutes when smoked]. When taken orally, particularly by drinking rather than chewing, the peak may be indistinct and can come and go over the course of the experience (Pendell 1995; Siebert 1994; Turner 1997; Valdés 1994; Valdés et al. 1987a; Wasson 1962; pers. comms.; pers. obs.). The plant has also had an obscure use as an antide-

pressant. One Australian suffering chronic depression, which had resisted prescribed treatments, chose to self-medicate with a chewed quid of 2-3 leaves taken three times a week. She experienced a complete remission of symptoms (Hanes 2001). The plant should be approached with care and respect, as it is truly a diviner's plant and does not appreciate being used casually or for idle recreation. Since the rediscovery of its remarkable activity, the plant has entered widespread cultivation [mostly from cuttings, as they rarely set seed], and both dried leaf and enriched extracts have become widely available. Following this, in 2002 the plant and products derived from it became illegal in Australia, and it appears the US may shortly follow suit (pers. obs.). Currently, the plant and *salvinorin A* are restricted for sale to minors in St Peter's, Missouri; illegal in Louisiana [along with a whole list of psychoactive plants, many of which contain no prohibited substances]; pending probable banning in several other US states; illegal/controlled as a category B drug in Denmark; illegal in Italy; controlled substance [*salvinorin A*] in Belgium; the herb prohibited for sale only, in Spain; illegal to import without doctor's prescription in Finland; and controlled in S. Korea (http://www.sagewisdom.org/new.html).

It would seem at this stage that most members of the genus will prove to possess varying degrees of psychoactivity, though so far none have been found with any great subjective similarity to S. divinorum. Many other Salvia spp. have been sampled and found to be psychoactive, and the distribution of diterpenoids [which seem to be the main active chemicals in Salvia spp.] including clerodanes, neo-clerodanes, labdanes, abietanes, etc. is widespread in the family Labiatae [eg. see also **Leonotis**, **Lagochilus**, **Scutellaria**] (friendly 1997; Lamius pers. comm.; pers. comms.; pers. obs.).

S. apiana roots have yielded cryptotanshinone, miltiodiol, salvicanol, ferruginol, 6,7-didehydroferruginol, 16-OH-6,7-didehydroferruginol, 6,7-didehydrosempervirol, lanugon Q, 6-deoxo-5,6-didehydrolanugon Q, 16-hydroxyroyleanone and other diterpenes; 16-OH-carnosic acid, oleanolic acid, ursolic acid, α-amyrin and an essential oil have also been found in the plant (González et al. 1992).

S. argentea has yielded salvigenin, *apigenin*, genkwanin, chrysoeriol, luteolin, hispidulin, eupatorin, 5-OH-7,4'-(MeO)2-flavone, rosmarinic acid and caffeic acid (Adzet et al. 1988).

S. coccinea aerial parts [harv. June, Italy] have yielded 0.055% salviacoccin, a neo-clerodane diterpenoid (Savona et al. 1982).

S. divinorum contains *salvinorin A* [divinorin A] as its main active constituent, a neoclerodane diterpenoid found at concentrations of 0.056-0.37% in dry leaf; 0.0015-0.007% salvinorin B [divinorin B] has also been found in the pharmacologically-inactive TLC fraction of the extract. Stems have yielded <0.063% *salvinorin A* (Bigham et al. 2003; Gruber 1997; Gruber et al. 1999; Lee et al. 2005; Munro & Rizzacasa 2003; Ortega et al. 1982; Valdés et al. 1984). More recently, a minor constituent of the active TLC fraction [banding together with *salvinorin A*] was identified as salvinorin C [divinorin C], present at c.10% of the active fraction; it is difficult to isolate without decomposing, though 0.0065-0.025% has been isolated. This compound may prove to be potently psychoactive, or synergistic with *salvinorin A*, based on the greater subjective effects experienced with the whole active fraction, as opposed to purified *salvinorin A*. This increased activity might instead be due to contamination of the salvinorin C extract with *salvinorin A* (Lee et al. 2005; Munro & Rizzacasa 2003; Valdés et al. 2000, 2001). The leaf also yielded the antrepellant loliolide [0.0004%] (Valdés 1986); terpenoids (-)-hardwickiic acid [0.0005-0.0006%], oleanolic acid [0.0003%], presqualene alcohol [0.006-0.01%], peplusol [0.0027%] and (E)-phytol [0.0026-0.005%]; and additional neoclerodane diterpenoids - divinatorins A [0.0042%], B [0.0048%], C [0.0004-0.0027%], D [0.0003%] & E [0.0002%], salvinorins D [0.0004-0.013%], E [0.0003%], F [0.0001%] and G [0.0002%], and salvinicins A & B; neophytadiene and stigmasterol were tentatively identified but not isolated (Bigham et al. 2003; Harding et al. 2005; Lee et al. 2005; Munro & Rizzacasa 2003). The diterpenoids produced by this species have been found to be concentrated in a resin accumulated in peltate glandular trichomes [1 of 4 types of trichomes observed on the plant] on undersides of leaves, stems and floral organs (Siebert 2004). As well as the potent κ-receptor agonist properties of *salvinorin A* which are now well-known, salvinorin B, salvinorin G and divinatorin D have been found to be weak agonists at the same receptor (Lee et al. 2005).

S. elegans showed strong binding affinity for muscarinic *acetylcholine* receptors (MacKenzie 2000; Wakea et al. 2000).

S. haematodes has yielded 7β-OH-20(29)-lupen-3-one (Buckingham et al. ed. 1994), flavonoids, glycosides, sterols, tannins (Islam et al. 1991) and c.0.14% *choline* (Balansard & Rizzo 1934).

S. mellisodora leaf contains an unidentified terpenoid which reacted similarly to *salvinorin A* in analysis; however, it did not seem to be identical and remains unidentified (Gruber 1997). Numerous neoclerodane-diterpenoids and mellisodoric acid have been found (Buckingham et al. ed. 1994).

S. miltiorrhiza contains a wide array of constituents, the most important being the diterpene ketones called tanshinones, which interact with BZ-receptors to varying degrees. The main constituent is tanshinone IIA [up to 0.5%] – also found are tanshinone I, 1,2-dihydrotanshinone I, cryptotanshinone, methylene cryptotanshinone, methylene tanshinquinone, tanshinol I & II, miltirone [a partial BZ-receptor agonist], 1,2-didehydromiltirone, 4-methylenemiltirone, Ro 09-0680, salvianolic acid, salviol and vitamin E, as well as essential oil. It is decocted in a dose of 2-15g or more a day. The tanshinones are extracted most efficiently with diethyl ether. Indole-3-butyric acid can increase tanshinone concentration in the roots. Aerial parts have yielded a new germacrane sesquiterpene, as well as abietane diterpenes (Bone 1996; Buckingham et al. ed. 1994; Chevallier 1996; Hsu et al. 1986; Huang 1993; Lee et al. 1991; Liu et al. 1995; Shimomura & Kitazawa 1991).

S. officinalis has yielded 0.7% [spring] to 1.5% [autumn] to 2% [summer] essential oil. For best results, leaf should be harvested when it has turned silvery, from its younger green stage. Essential oil yield is highest when plants receive regular harvesting [at least twice a year, once in summer], containing the psychoactive *thujone*s in some strains [highest in winter and summer, lowest in spring]; 17-43% α-*thujone*, 1.7-8.5% β-*thujone* [or up to 66.83% total *thujones*], 0-33.3% *camphor* [highest in spring], 3.7-4.5% *borneol*, 0-14% 1,8-cineole, 10.8-30.3% caryophyllene, 8.45-33.7% humulene, 0.9-10.2% eucalyptol, 0.5-1% linalool, 0.5-3% limonene, 1.7-6.5% α-*pinene* and others have been found. It also contains oestrogens, as well as tannins, mucilage and vitamins, and bitter diterpene diphenol lactones called picrosalvins. As picrosalvin, dry leaves have yielded 1.8%, and fresh leaves yielded 1.3%. Contains more α-*thujone* after flowering (Battaglia 1995; Bianchi et al. 1989; Brieskorn & Fuchs 1962; Brieskorn et al. 1961; Bruneton 1995; Chiej 1984; Ivanić & Savin 1976; Putievsky et al. 1986a; Tucker et al. 1980). Also, c.0.14% *choline* has been found (Balansard & Rizzo 1934). The herb causes slight inhibition of plasma AChE (Orgell 1963b).

S. plebeia has been shown to contain nepetin, neopitrin, hispidulin, homoplantaginin, 4-OH-phenyllactic acid and caffeic acid (Jiang et al. 1987).

S. sclarea has yielded 0.1% essential oil, consisting of mainly linalool, with linalyl acetate, *pinene*, citronellol, limonene and others; and the labdane diterpenoids sclareol and 13-episclareol (Chevallier 1996; Lawless 1994; Popa & Lazur'evskii 1963), which are mostly found in the residue after distillation of the essential oil; as well as salvigenin, *apigenin*, genkwanin, luteolin, chrysoeriol, 5-OH-7,4'-(MeO)2-flavone, rosmarinic acid and caffeic acid (Adzet et al. 1988); c.0.14% *choline* has also been found (Balansard & Rizzo 1934). *Thujone* is found in seeds, and in 5-day old seedlings (Balansard & Rizzo 1934; Popa & Lazur'evskii 1963; Verzár-Petri & Then 1974).

S. sonomensis contains a *camphor*-like substance (Pendell 1995).

S. splendens contains the diterpenoids salviarin [0.007%] (Savona et al. 1978), splendidin [0.04%] (Savona et al. 1979), splenolides A, B and C (Hu et al. 1997), as well as salvianin, bisdemalonyl-salvianin, monodemalonyl-salvianin, salviadelphin, bisdemalonyl-salviadelphin, monodemalonyl-salviadelphin, dimalonylawobanin, monardein and monodemalonyl-monardein (Buckingham et al. ed. 1994).

S. triloba leaf bore the most essential oil during summer [1.4-3.8%], though yield of total herbage is highest in spring, and autumn harvests gave +- intermediate results. Inflorescences have yielded 0.22% essential oil. Oil from all parts is rich in 1,8-cineole [42.4-64%], also containing α-*pinene*, *camphor* [3.3-9.1%] and 1-7% *thujones*. Roots have yielded the abietane diterpenes sugiol, royleanone and 7α-acetoxyroyleanone (Liu et al. 1995; Putievsky et al. 1986b; Tucker et al. 1980). The plant has also yielded trilobinol, trilobinone and carnosol (Buckingham et al. ed. 1994; Bruneton 1995).

Many other Salvia spp. contain diverse diterpenoids, such as S. cyanescens, S. recognita, S. reflexa and S. thymoides (Gökdil et al. 1997; Maldonado & Ortega 1997; Nieto et al. 1996; Tan et al. 1998), which only comprise a very small selection. *Thujone* is also found in trace amounts in the essential oils of S. aethiopis [1.1%], S. glutinosa [0.3%], S. nemorosa [0.7%] and S. verticillata [0.6%], growing wild in Yugoslavia (Ivanić & Savin 1976).

Salvia divinorum is a perennial herb, 0.5-1.5m tall, with flowering stems 1-3m long. Stems hollow, quadrangular, with flanged angles, hirtellous, green, translucent, crisp. Leaves opposite, elliptic to ovate, apex acuminate to caudate, base attenuate, up to 10-30cm long, 5-10cm wide, glabrous above, glandular-punctate below, irregularly crenate-serrate margins. Racemes erect, simple, 30-40cm long, internodes 2-4cm; cymules with 3-12 flowers; rachis hirsute, glabrate; bracts ovate, concave, sessile, basally rounded, apex acuminate-cordate, 1-3cm long, 0.6-1cm wide, tardily deciduous, mainly violet; pedicels hirsute, slender, straight, violet, 4-9mm long. Calyx 10-12mm long, lips subequal, glabrate to glandular-puberulent, violet; upper lip 1.5mm long with 3 major veins. Corolla 28-32mm long, sigmoid, densely villous with translucent hairs 0.5-2mm long, white, glabrous within, lips becoming tinged with blue in age; tube 19-22mm long, 2mm high, 1.2mm wide at narrowest near throat; galea 8-10mm long; lower lip cupped, 5mm long and 7mm wide when flattened, middle lobe emarginate. Stamens glabrous, white, slightly arcuate, 15-16mm long, rudders 10-11mm long, entire; anthers 2mm long; pollen white. Style 27-32mm long, densely bearded below stigma, white. Gynobase horn 3mm long, 1.2mm wide, white, glabrous. Nutlets 1.8-

2mm long, 1-1.2mm wide at maturity, dark brown. Fl. Sep.-May [though I have seen it flowering in August in NSW, Australia (pers. obs.)].

Endemic to the Mazatec zone of the Sierra Madre Oriental, Oaxaca, Mexico; on black soil in ravines close to primary or secondary cloud and tropical evergreen forest, 300-1800m (Epling & Játiva-M. 1962; Ott 1996a).

The plants only flower when stems have grown to 2m or more, and very rarely set viable seed. Spreads by rooting at the nodes where the stems bend to touch the ground. Plants are grown in discrete locations in the forest, and are not overtly maintained, being more or less free to grow wild, which they do readily. It is uncertain whether it exists in a truly wild state. It is a cultivar, the parents of which are unknown, and some inhabitants of Oaxaca say it is not native to that area.

S. divinorum does not tolerate strong direct sunlight for extended periods [if not yet hardened, it may not withstand even short periods of direct sunlight]; requires a warm, humid, moist environment, though not so moist as to cause rotting of the stems. Outside of semi-tropical areas, it should be grown in a greenhouse or humidity tent [with good air circulation] and regularly misted. Although frost protection is required, some growers have managed to adapt their plants to grow in well-chosen outdoor locations in temperate zones [such as Oakland, California and Sydney, Australia]. In such areas, it is sometimes best to keep them in pots so they can be brought inside during winter; however, some misting should be maintained at this time as the dry atmosphere inside a house may adversely affect the health of the plants. Soil should be kept moist on top, though take care not to over-water. Roots easily from cuttings. Grow in soil with pH 6.1-6.6. A successful soil mixture for this plant consisted of 1 part aged grass cuttings; 1 part compost; 1 part coarse sand; ½ part aged steer manure; 3 parts rich soil. When watering and misting, avoid using water more than 150ppm hardness, or with sodium levels above 50ppm. Plants may be victim to attack by whiteflies [attracted to yellow traps], aphids [prey to ladybugs], spider mites, scale insects [hand remove] and snails. Whiteflies, aphids and scale insects may also be killed and removed by application of a spray made from 4 parts water, 1 part rubbing alcohol and 1 part liquid castile soap, which is harmless to the plant and to the human consumer, though the plants should be rinsed afterwards. Leaves that drop from the plant naturally can still be used sacramentally, though they may only have c.2/3 the potency of leaves harvested whilst still attached to the plant (Ott 1996a; Sociedad 1998; Turner 1997; Valdés et al. 1987a; pers. comms.; pers. obs.).

SANTALUM

(Santalaceae)

Santalum album *L.* **(S. myrtifolium** *Roxb.***; S. verum** *L.***)** – Indian sandalwood, white sandalwood, yellow sandalwood, white saunders, santal, anindita, chandan, chandanam, srighanda, t'an hsiang, t'an xiang, t'an muh

Santalum lanceolatum *R. Br.* **(S. oblongatum** *R. Br.***)** – sandalwood, northern sandalwood, Queensland sandalwood, bush plum, plum bush, plumwood, black currant tree, bolan, tharragibberah, gumamu, yarnguli, birmingal

Santalum murrayanum *(Mitchell) Gardner* – bitter quandong, ming

S. album, used in India for thousands of years, is valued for the scent of its essential oil, as well as for its medicinal properties. The ancient Egyptians imported the tree from India for use in embalming, perfume and cosmetics; in Ceylon it was also used in embalming. Temples and carvings were often made of sandalwood, partly because it is immune to termite attack. The wood is burned as incense in funeral pyres and during some religious ceremonies in India, as it is believed to repel evil and invite forces of protection and healing. The Parsi use sandalwood, pomegranate wood, and frankincense [see **Boswellia**] to feed the sacred fire in Zoroastrian observance. The Japanese sometimes burn it for Shinto ceremonies, and at Buddhist shrines. Yogis say that the fragrance of sandalwood is that of the "subtle body, centre of the highest insight and enlightenment", and male practitioners of tantric yoga use it to help awaken the kundalini energy. Therapeutically, S. album is 'uplifting', 'exhilarating', aphrodisiac, sedative, nerve tonic, diuretic, antipyretic, diaphoretic, astringent, antiseptic, antiphlogistic, antispasmodic, carminative, emmolient and expectorant. In Unani medicine, it is said to be good for the memory. The wood is also used in TCM in a dose of 2-3g, as an analgesic, stomachic and carminative, and to treat nervous gastralgia (Battaglia 1995; Bremness 1994; Cunningham 1994; Haug 1884; Keys 1976; Kirtikar & Basu 1980; Lawless 1994; Nadkarni 1976).

The berries of the Australian S. lanceolatum are edible, though not as pleasant-tasting as 'quandong' fruits from S. acuminatum (Glowinski 1997). S. lanceolatum berries are said to be slightly narcotic or soporific when eaten in large quantities. The leaves are burnt by some indigenous peoples to 'smoke themselves' before going on a long trip, in order to gain strength for the journey. Newborn babies are also smoked in such a fashion, to make them "strong and placid" [see also **Acacia**, **Eremophila**]. The leaves are used to treat sores, boils and gonorrhoea; leaf and bark decoction is purgative; outer wood decoction treats chest problems; and root infusion is applied externally for rheumatism and itching (Aboriginal Communities 1988; Lassak & McCarthy 1990; Low 1990). The leaves have also been burned to repel mosquitoes (Cribb & Cribb 1981; Low 1990). Indigenous people at Lake Boga reportedly used the bark and roots of S. murrayanum to prepare a 'stupefying' drink (Low 1990). The seeds and roasted rootbark may be used as food (Low 1991a). A decoction of S. obtusifolium bark has been consumed to treat pains and constipation (Lassak & McCarthy 1990). The Australian S. spicatum is sometimes used to make an inferior quality sandalwood oil, as well as to make 'joss sticks' and cheap perfumes in China (Lawless 1994). In TCM, the heartwood is sometimes substituted for that of S. album (Huang 1993).

S. album oil is distilled from the roots and heartwood of trees at least 30-50 years old, yielding c.5.5% essential oil. Good quality oil contains large amounts of santalols [89-90%], 3.5% santyl acetate, 2-3% santalenes; as well as norecasantalal, norecasantalic acid, norecasantalol, α- and β-santalal, β-santenol, santalone, teresantalal, teresantalol, α-teresantalic acid, tricycloekasantal, tricycloekasantalol and many other compounds (Battaglia 1995; Lawless 1995; Nadkarni 1976; Simonetti 1990). One of the constituents is very similar to androsterone [a male pheromone hormone] (Lawless 1994).

S. lanceolatum leaves yield traces of essential oil, rich in lanceol [a sesquiterpenoid alcohol] and many unidentified components; the leaves also contain saponins, and high levels of calcium and potassium (Aboriginal Communities 1988; Lassak & McCarthy 1990). Leaf from Miles, Queensland [harv. Jun.] tested strongly positive for alkaloids (Webb 1949).

S. murrayanum leaves yielded 0.076% pyrrolizidine alkaloids – laburnine benzoate ester, laburnine thioacrylate ester and laburnine tiglate ester [see **Laburnum**]. In cats, 10mg/kg [i.p.] alkaloids caused pupil dilation and relaxation of the blinking membrane; 35mg/kg caused prostration. I.v. doses in dogs caused laboured breathing and scratching. 50mg/kg [oral] produced analgesia in 80% of test animals (CSIRO 1990).

S. obtusifolium leaves have yielded *glutamic acid*, proline and OH-proline (Lassak & McCarthy 1990).

Santalum album is a small, evergreen glabrous tree with slender, drooping branches; sapwood white and odorless; heartwood yellowish-brown, strongly scented. Leaves opposite, subcoriaceous, 3.8-6.3 x 1.6-3.2cm, elliptic-lanceolate, subacute, glabrous, entire, thin, base acute; petioles 1-1.3cm long, slender. Flowers hermaphrodite, brownish-purple, inodorous, in terminal and axillary 3-chotomous paniculate cymes shorter than the leaves; bracts minute; perianth tube campanulate, adnate to base of ovary, limb of 4 valvate triangular segments with a tuft of hair on the face; stamens 4, exserted, adnate to base of perianth lobes, alternating with 4 rounded obtuse scales; filaments slender, short; anthers ovate, cells distinct, parallel. Disc of fleshy spathulate scales, projecting between stamens; ovary at first free, ultimately ½-inferior; ovules 2-3, inserted below summit of long acuminate free central column; style elongate; stigma 2-3 lobed. Fruit a globose drupe, 1.3cm diam., purple-black; endocarp hard, ribbed. Seeds subglobose.

Well drained soil in forests; w. peninsula of India; cultivated elsewhere (Kirtikar & Basu 1980). Suckers on natural host trees to obtain its nutrients (Simonetti 1990).

S. acuminatum is cultivated from seed. The stone of the fruit is cracked in a vice, and the seed coat removed, before soaking the seed in chlorinated bleach for c.30min. Wash seed in boiled water; some choose to dust with fungicide before planting in sterile, moist vermiculite in brand-new [ie. clean] plastic bags, tied at the top. Leave bags in a dark and warm place [16-20°C]; germination should occur within 3 weeks. Plants require roots of a host plant; plant out seedlings in a pot with another plant growing in it, such as lucerne; poke a thin hole with a pencil to feed the roots into carefully, so as not to disrupt the required root contact (Glowinski 1997).

'Red sandalwood' [Pterocarpus santalinus] is a tree from the Leguminosae, unrelated to true sandalwoods, though its heartwood is also burned as an incense (Bremness 1994). The 'bitter quandong' S. murrayanum should not be confused with Elaeocarpus spp., some of which are also known as types of 'quandong' in Australia.

SASSAFRAS

(Lauraceae)

Sassafras albidum *(Nutt.) Nees* **(S. officinale var. albidum** *(Nutt.) S.F. Blake***; S. officinalis** *Nees et Eberm.***; S. sassafras** *(L.) H. Karst.***; S. variifolium** *(Salisb.) Kuntze***; Laurus albida** *Nutt.***; Laurus sassafras** *L.***)** – sassafras tree, fennel wood

Sassafras is a popular herb with native N. Americans, who had many medicinal uses for it as well as using it for its aphrodisiac properties. The Cherokee use a tea of sassafras to purify the blood, wash sore eyes, apply to wounds, and to treat skin diseases, rheumatism, venereal disease,

diarrhoea, colds and obesity – and, combined with other herbs, as an anthelmintic. They mix the flowers with beans for planting, and use the wood for furniture (Hamel & Chiltoskey 1975). All parts of the tree have been utilised for medicine, though the root bark is the strongest. Dried root bark was smoked ritually in smoking mixtures by many tribes [see **Nicotiana**, **Arctostaphylos**], and the Ojibway boiled the root pulp specifically for its 'narcotic' properties (Rätsch 1992). The ground leaves ['file powder'] are used to thicken Cajun soups, and the essential oil ['sassafras oil'] has been used to flavour tobacco [see **Nicotiana**] and toothpaste, and to scent soap and perfumes (Bremness 1994; Simonetti 1990). Sassafras oil is also effective for killing head lice (Battaglia 1995; pers. obs.).

Until recently sassafras was used to flavour root beer, though it is now banned as a food additive by the FDA on the premise that *safrole* [the main constituent of the essential oil] is carcinogenic and hepatotoxic (Hall 1973; Segelman et al. 1976). Because *safrole* is only 1/14th as carcinogenic as the ethanol in an alcoholic beverage [which is, of course, also hepatotoxic with continued exposure] (Ames et al. 1987), and as it is well known that no pure essential oils should be taken internally in quantity due to risk of hepatotoxicity, it may be more likely that this is a thinly veiled attack on the psychoactive potentials of the herb. Perhaps more seriously, from a legal perspective, the essential oil has been a favoured starting-point for illicit synthesis of MDA and MDMA. Sassafras oil is now very difficult to obtain in Australia, most likely for similar reasons (pers. obs.). Commercial sassafras oil has also been obtained from Ocotea pretiosa ['Brazilian sassafras oil' – see *Endnotes*] and **Cinnamomum** camphora ['Chinese sassafras oil'] (FAO 1995). See also **Atherosperma**, **Doryphora**.

The root bark may be brewed as a tea [28g/pint water is one suggested dose] (Gottlieb 1992), which would rely on the hydrophobic oils being suspended in the hot water, and water-solubility of some of the alkaloids. An alcohol extract may be a more viable approach. If you can obtain sassafras oil, it can be dropped under the tongue in small amounts only [10-15 drops] (pers. obs.). It has been suggested that the dried essential oil [presumably dried at low temperature] may be ingested [100-200mg] (Gottlieb 1992). I have not attempted this latter method, nor do I know of anyone who has. The effects of the essential oil taken sublingually may be perceived as mildly euphoric and stimulating, taking up to several hours to become particularly noticeable. I have also had very good effects from adding sassafras oil [again, c.10-15 drops] to sassafras-free root beer, combined with smoked **Cannabis** (pers. obs.). The essential oil may also be applied by muscular massage [see **Myristica**] (Torsten pers. comm.). There is at least one death on record – one man who ingested 1tsp of sassafras oil suffered "CNS depression, vomiting and nausea" before death. According to some, even "a few drops" has been lethal. In any case, extended or high-dose internal use would be expected to induce degeneration of the liver and possibly carcinogenesis (Battaglia 1995).

S. albidum essential oil [for commerce steam-distilled from the inner rootbark, which is harvested in summer and autumn] is found in all plant parts, but concentrated in the rootbark. One fresh sample yielded 3% essential oil by solvent extraction. The essential oil may contain [12.7-]70-90% *safrole*, 0-16.38% *asarone*, 0.57% *eugenol*, 1.1% *methyleugenol*, 0.61-27.4% 5-MeO-*eugenol*, 0.78% *elemicin*, 0.39% *myristicin*, 0.53% *apiole*, 0.6% *estragole*, 3.25-4.52% *camphor*, 0.1% *thujone*, α-*pinene*, traces of *anethole*, 10.17% piperonylacrolein, 6.5% coniferaldehyde and many other trace components. Also found in the root bark are heliotropin [piperonal], the aporphine alkaloids magnolol [antidepressant, muscle relaxant, sedative; see **Magnolia**], isomagnolol and boldine [hypnotic sedative], and the benzyl-tetrahydroisoquinoline alkaloid reticuline, as well as sassafrasine, sassafrasinine and (+)-3-(3,4-methylenedioxyphenyl)-propane-1,2-diol (Harborne & Baxter ed. 1993; Kamdem & Gage 1995; Lawless 1995; Segelman et al. 1975, 1976a; Sethi et al. 1976; Simonetti 1990).

Sassafras albidum is a shrub or tree up to 30m tall, aromatic. Leaves long-petioled, variable even on the same plant from ovate to deeply 2-3(-5)-lobed, 3-nerved, c.12cm long, at first silky beneath, pubescence either persistent or deciduous. Flowers greenish-yellow, produced from the apex of the branches of the previous year, appearing with the young leaves of the season in 5cm long racemes; peduncles and pedicels at first short, at maturity red and up to 10cm long; calyx 6-parted, persistent; stamens 9, the inner 3 each bearing a pair of stalked glands at base; anthers when mature splitting open towards the centre of the flower, 4-celled, opening by 4 valves; pistillate flowers with 6 short staminodia; pedicels expanded at apex at maturity, forming with the persistent calyx a cup-like base below the fruit. Drupe dark blue, ellipsoid, c.1cm long. Fl. Apr.-May.

In dry or rich woods, roadsides and old fields; Massachusetts and s. Ontario to Michigan, south to Florida and Texas (Gleason 1952).

May be easily cultivated in almost any soil. Sow seeds as soon as they are ripe; they become dormant once dry (Torsten pers. comm.). May also be propagated from suckers, or from root cuttings. In colder areas prefers a warm, sunny position (Grubber 1973).

SCELETIUM and some other similar Aizoaceous herbs

(Aizoaceae/Mesembryanthemaceae)

Aptenia cordifolia *(L. f.) Schwantes* **(Mesembryanthemum cordifolium** *L.***)** – brakvygie, ibohlololo
Bergeranthus scapiger *(Haw.) N.E. Br.*
Carpobrotus acinaciformis *(L.) L. Bol.* **(Mesembryanthemum acinaciforme** *L.***)** – Hottentot fig, sour fig, elandsvye, gouna, strandvy, suurvy, gaukum, hotnotsvy
Carpobrotus edulis *(L.) L. Bol. ex N.E. Br.* **(Mesembryanthemum edule** *L.***)** – Hottentot fig, kaffir fig, marine fig, Sally-my-handsome, choroes, balsamo, widdana, vyerank, gaukum, hotnotsvy, perdevy, suurvy
Drosanthemum bicolor *L. Bol.*
Drosanthemum floribundum *(Haw.) Schwant.* **(D. candens** *(Haw.) Schwant.***; Mesembryanthemum candens** *Haw.***; M. floribundum** *Haw.***)**
Drosanthemum hispidum *(L.) Schwant*
Khadia acutipetala *N.E. Br.* – khadi
Lampranthus aureus *(L.) N.E. Br.*
Lampranthus blandus *(Haw.) Schwantes*
Lampranthus coccineus *(Haw.) N.E. Br.*
Lampranthus roseus *(Willd.) Schwant.*
Lampranthus spectabilis *(Haw.) N.E. Br.* **ssp. spectabilis 'Mesembryanthemum arachnoideum'**
Mesembryanthemum cristallinum *L.* **(Crytophytum cristallinum** *(L.) N.E. Br.***)** – ice plant, diamond fig, brakslaai, slaai, soutslaai, slaaibos
Mestoklema tuberosum *(L.) N.E. Br. ex Glen* **(Mesembryanthemum tuberosum** *Harv.***)**
Sceletium anatomicum *(Haw.) L. Bol.* **(S. dejagerae** *L. Bol.***; S. emarcidum** *(Thunb.) L. Bol. ex H.J. Jacobsen***; Mesembryanthemum anatomicum** *Haw.***; M. emarcidum** *Thunb.***; Tetracoilanthus anatomicus** *(Haw.) Rappa et Camarrone***)** – kanna, channa, guena, skeleton-leaved fig-marigold
Sceletium expansum *(L.) L. Bol.* **(S. regium** *L. Bol.***; Mesembryanthemum expansum** *L.***; Pentacoilanthus expansus** *(L.) Rappa et Camarrone***)** – kanna, channa, kou, kougoed
Sceletium joubertii *L. Bol.*
Sceletium strictum *L. Bol.*
Sceletium tortuosum *N.E. Br.* **(S. boreale** *L. Bol.***; S. compactum** *L. Bol.***; S. concavum** *(Haw.) Schwantes***; S. framesii** *L. Bol.***; S. gracile** *L. Bol.***; S. namaquense** *L. Bol.***; S. ovatum** *L. Bol.***; S. tugwelliae** *L. Bol.***; Mesembryanthemum concavum** *Haw.***; M. namaquense** *Sond.***; M. tortuosum** *L.***; Tetracoilanthus concavus** *(Haw.) Rappa et Camarrone***)** – kanna, channa, kou, kougoed

Sceletium varians *(Haw.) Gerbaulet comb. nov.* **(S. subvelutinum** *L. Bol.***; Mesembryanthemum varians** *Haw.***)**
Trichodiadema bulbosum *(Haw.) Schwant.* **(T. stellatum** *Mill.***; Mesembryanthemum stellatum** *Mill.***)** – kieriemoer, koeriemoer, karremoer

For convenience, many different Aizoaceous plants will be discussed here, due to their similar ethnobotanical usages, or due to possessing similar chemistry. Many plants once classified as Mesembryanthemum spp. have since been reclassified, and are now known by some of the synonyms listed above. See also **Delosperma** and **Nananthus**. Sceletium spp. have been regarded as a subgenus of Phyllobolus, though Sceletium has since been revised, and retained as a genus. The name derives from the 'skeletonised' appearance of the persistent leaves of prior season's growth (Gerbaulet 1996).

It was first reported in the 1600's that the Hottentot and other S. African groups [eg. the Namaquaa] made use of small herbs called 'kanna' [or slight variations on that term], recorded to consist particularly of Sceletium expansum and S. tortuosum, as well as other members of the group, such as S. anatomicum and Carpobrotus edulis. They are still used today under that name, but confusion exists as to the identity of some of the earlier reported kannas, due partly to early descriptions of the effects of the drug [probably exaggerated] which are yet to be adequately demonstrated from Aizoaceous plants. Kanna is often associated with the eland, a shamanic animal also associated with fertility, healing, divination and trance. The herbs are usually prepared to make a product called 'kougoed', which is ready for chewing. Older texts indicate that around October, when Sceletium spp. are fruiting, might be the preferred time of year for harvest. The whole plant, or aerial parts only, are beaten together and then twisted into a 'pig-tail' and left in the sun to ferment for 8 days in a skin, canvas or [today] plastic bag [with turning after 2-3 days]; it is then dried, and usually chewed straight afterwards. For a quicker process, the fresh herb is buried in a sand oven for 1 hour before being removed and dried. Sometimes it is chewed without fermentation, though many native users attest it is not psychoactive until fermented; sometimes the residue is smoked after chewing, and may be consumed with **Cannabis**; occasionally, it may be snuffed, a route by which it is more potent. The primary reasons for employing kougoed are to quench thirst, increase strength, and to inebriate, either recreationally or in religious rites (Festi & Samorini 1995; Schultes 1966, 1967a; Smith, M.T. et al. 1996, 1998; Tyler 1966; Watt & Breyer-Brandwijk 1932, 1962). Some undetermined species, presently in commercial circulation as Sceletium sp. 'nova' or S. aff. tortuosum and Sceletium sp. SB661, have been found to have similar properties to the above species (friendly pers. comm.; Sacred Succulents 2002).

Leaf of S. tortuosum is also chewed by the Hottentot as an analgesic for toothache and abdominal pain; it was also once used by Cape farmers as a sedative, in the form of a decoction or tincture. The juice of S. anatomicum is consumed as a sedative in the Willowmore district, and indigenous mothers may give drops of the fresh juice to their children to help them sleep peacefully. Mesembryanthemum cristallinum has also been reported as causing intoxications, and M. arachnoideum [for which I can find no other mention of its existence as a species name] is said to possess 'very powerful properties'. C. edulis fruit was once infused and given by the Hottentot to ease birth; they also smeared the leaf juice over the newborn to make it strong and nimble. The astringent, diuretic leaf juice has also been gargled for sore throats and digestive problems. Roots [occasionally fruits] of M. acutilobum, Khadia acutipetala, Mestoklema tuberosum and Trichodiadema bulbosum have been used in brewing beer or 'khadi' mead [see also **Delosperma**, *Methods of Ingestion*], and sometimes as a yeast substitute in bread-making. The roots are said to cause intoxication and delirium. The Zulu use a leaf infusion of a Mesembryanthemum sp. to "relieve fearful dreams accompanying heart weakness", and other unidentified members of this genus have been applied for a variety of purposes – to treat skin sores, stomach troubles, cystitis, syphilis [with juice of a Tragia sp.], and as an emetic (Festi & Samorini 1995; Hargreaves 1999; Smith, M.T. et al. 1996; Steyn 1934; Watt & Breyer-Brandwijk 1932, 1962).

Several members of the genus Carpobrotus grow in Australia, where they are known as 'pigface' [C. glaucescens, C. modestus, C. rossii and C. virescens]. The fruits, and rarely also the leaves are eaten as food (Low 1989, 1991a). The leaf juice of C. glaucescens is reputedly effective in relieving the pain and irritation of bites from both biting midges and the Portuguese man-of-war ['bluebottle'] (Cribb & Cribb 1981). C. edulis is also naturalised in some coastal areas of southern and eastern Australia (Prescott & Venning 1984), and contemporary bioassays of this species growing in the US have [in some instances] revealed it to sometimes be more potent than Sceletium tortuosum, though of similar quality (pers. comms.). C. rossii, which is much more common than C. edulis in Australia [and looks very similar], has been prepared and ingested in the same manner as S. tortuosum, and appears to be inactive (pers. obs.).

Aptenia cordifolia is used by Zulu healers in S. Africa as one of their important medicinal plants. The leaves may be infused to relieve sore throat and perspiration; the herb is also anxiolytic, and acts as an antiinflammatory when applied externally. Interestingly, a black powder prepared from the plant is reputedly endowed with magical properties, and is used to protect against sorcery (Van Wyk & Gericke 2000; Van Wyk et al. 1997). Prepared in the same manner as Sceletium spp., this common and attractive ornamental herb has been found to have similar effects to S. tortuosum, but is of lower potency (pers. comms.).

These herbs contain *mesembrine*-type alkaloids [structurally similar to the crinane-type alkaloids found in plants of the Amaryllidaceae – see **Narcissus**]. They are divided into 4 subgroups – *mesembrine*, joubertiamine, pyridine-pyridone and tortuosamine, collectively known as Mesembryanthemum or Sceletium alkaloids (Jeffs 1981; Popelak & Lettenbauer 1967; Smith, M.T. et al. 1996). In earlier literature they have been compared to *hyoscyamine* or *cocaine* in action, though this is misleading, as the CNS effects are not equivalent, only some common properties being shared. Recently, *mesembrine*, mesembranol, mesembranone, and related alkaloids have been found to act as *serotonin*-reuptake inhibitors [SRIs]. These compounds, and synthetic derivatives of them [as well as prepared S. tortuosum and extracts of it], are being investigated for their potential in treating "depressive states, psychological or psychiatric disorders with an anxiety component, alcohol and drug dependence, bulimia nervosa and obsessive-compulsive disorders" (Gericke & Van Wyk 1997). Some people have experienced toxic symptoms resembling *serotonin* syndrome [see *Influencing Endogenous Chemistry*] from combining S. tortuosum with **Griffonia** simplicifolia extracts rich in *5-hydroxytryptophan*. Caution is advised when consuming *mesembrine*-type alkaloids with anything that may boost *serotonin* levels (friendly pers. comm.).

Traditionally kanna has been said to cause an excited intoxication, though until recently, earlier contemporary experiments [with 5g chewed plant; 15g decocted plant; or 150mg *mesembrine*] had produced inconclusive results – mydriasis, analgesia, loss of appetite, tingling in mouth, gagging reflex, congested feeling in the head and noises in the ears. Recently, distribution of kanna plants and kougoed preparations has become more widespread, and modern psychonauts have rediscovered that, besides chewing or smoking, snuffing the powdered material can produce strong effects, consisting of some or all of the above, as well as calm euphoria or mood-enhancement with clear thoughts, accompanied by a state of relaxed alertness and anxiolysis. For snuffing purposes it is best to powder the prepared herb in an electric coffee grinder, and snuff the fine powder that collects on the inside of the lid. For some, the prepared, powdered herb may be active sublingually in doses as small as 30mg. A more common dosage may be 50-200mg via this route; as little as 20-30mg may be required for snuffing. Kanna also synergises well with **Cannabis** and alcohol. The plants also are usually rich in oxalates [3.6-5.1% or more], which are highly acidic and astringent, and can have toxic effects in large amounts; this is the reason for the fermentation or heat-treatment of kanna, as this process degrades the oxalates (friendly pers. comms.; Smith, M.T. et al. 1996; Steyn 1934; Watt & Breyer-Brandwijk 1962; pers. obs.). However, oxalate-bearing species used in brewing fermented beverages or in bread making have been known to result in toxicity (Hargreaves 1999).

All species tested by M.T. Smith et al. (1998) were cultivated in Natal, S. Africa, and harvested at 3-4 years of age in winter, before flowering.

Aptenia cordifolia may contain significant levels of *mesembrine*-type alkaloids, as compared to many other Aizoaceae, though still only 13.6% of the levels found in Sceletium tortuosum. *Mesembrine* [c.9.7% of extract], 4'-O-demethylmesembranol [c.14.4% of extract] and 3 unidentified compounds were observed; 2 of these, comprising c.4.8% of the extract, appear to be indoles (Smith, M.T. et al. 1998); A. cordifolia also earlier tested positive for alkaloids (Steyn 1934).

Bergeranthus scapiger was shown to contain small amounts of mesembrenone [mesembrenine, or mesembrinine] and 4'-O-demethylmesembranol (Smith, M.T. et al. 1998).

Carpobrotus acinaciformis is said to contain *mesembrine* in leaves and fruits, as well as malic acid and citric acid [and their calcium salts] in the leaves (Watt & Breyer-Brandwijk 1932).

C. edulis has not been examined for alkaloids, but has yielded up to 17.1% catechol tannins, as well as malic acid and citric acid [and their calcium salts] (Watt & Breyer-Brandwijk 1962). Independent psychonauts have sometimes found it to be more strongly active than Sceletium tortuosum (pers. comms.).

C. rossii has given negative tests for alkaloids (CSIRO 1990).

Drosanthemum bicolor has been shown to contain small amounts of mesembrenone, 4'-O-demethylmesembranol, and an unidentified indole compound.

D. hispidum var. hispidum has been shown to contain small amounts of mesembrenone and 4'-O-demethylmesembranol.

Lampranthus aureus has been shown to contain small amounts of mesembrenone and 4'-O-demethylmesembranol, as well as 2 unidentified compounds, one of which [present in large relative quantities] appears to be an indole.

L. blandus contained small amounts of mesembrenone, as well as 2 unidentified compounds, one of which appears to be an indole.

L. coccineus contained small amounts of mesembrenone and an unidentified compound.

L. roseus contained small amounts of mesembrenone and an unidentified indole.

L. spectabilis contained small amounts of mesembrenone, 4'-O-demethylmesembranol and 2 unidentified compounds, one of which appears to be an indole (Smith, M.T. et al. 1998).

Mesembryanthemum cristallinum has yielded large quantities of oxalic acid, 43%[!] sodium and potassium salts [including potassium oxalate], as well as an uncharacterised alkaloid (Steyn 1934; Watt & Breyer-Brandwijk 1932).

Sceletium anatomicum aerial parts have yielded *mesembrine* (Rimmington & Roets 1938).

S. expansum has yielded *mesembrine* from the whole plant [up to 0.3% in leaves; up to 0.86% in roots and stems], and *mesembrine* and mesembrol from the leaf wax (Hartwich & Zwicky 1915).

S. joubertii has yielded 0.033-0.1% crude alkaloids, including (S)-joubertiamine, dehydrojoubertiamine [trace], dihydrojoubertiamine and joubertinamine [0.009% w/w], as well as *hordenine* (Arndt & Kruger 1970; Psotta et al. 1979). Gerbaulet (1996) regarded S. joubertii as a synonym of S. tortuosum, though this would seem unlikely on the basis of their quite different chemistry.

S. strictum [3yr-old cultivated plant] has yielded 2.65% crude alkaloids; over half was 4'-O-N-demethylmesembranol and 4'-O-N-demethylmesembrenol, as well as containing mesembranol [mesembrinol], mesembrenol, O-acetylmesembrenol, *mesembrine* and mesembrenone (Jeffs et al. 1970). Sceletenone, channaine [thought to be an artefact of extraction] and N-demethylformyl-mesembrenone have also been found (Abou-Donia et al. 1978; Trout & Friends 1999).

S. tortuosum stem and root have yielded 1.43% alkaloids, including 0.86% *mesembrine*; leaves yielded 0.3% *mesembrine* (Hartwich & Zwicky 1915; Rimington & Roets 1938), probably measured as a crude mixed alkaloid. As S. namaquense, up to 1% *mesembrine* has been reported (Jeffs 1981), and up to 4.6% crude alkaloids, including [besides *mesembrine*] mesembrane, mesembrenone, mesembranone [may be mesembrenone?], mesembranol, sceletenone, tortuosamine, formyltortuosamine, N-acetyltortuosamine, channaine [probably an artefact of extraction], 3'-MeO-4'-O-methyljoubertiamine and Sceletium alkaloid A4. Mesembrol and *mesembrine* are found in the leaf wax (Bodendorf & Krieger 1958; Capps et al. 1977; Jeffs et al. 1971; Smith, M.T. et al. 1996; Snyckers et al. 1971; Watt & Breyer-Brandwijk 1962). In another test, the whole plant [fresh] was shown to contain predominantly *mesembrine*, followed by large amounts of mesembrenone, as well as 4'-O-demethylmesembranol and traces of 2 unidentified compounds, one of which appears to be an indole (Smith, M.T. et al. 1998).

S. varians has yielded O-methyljoubertiamine and 2,3-dihydrojoubertiamine methyl ester (Smith, M.T. et al. 1996; Trout ed. 1997a); as S. subvelutinum, it has yielded joubertiamine, dehydrojoubertiamine, dihydrojoubertiamine, O-methyljoubertiamine, O-methyldehydrojoubertiamine, O-methyldihydrojoubertiamine and *hordenine* (Herbert & Kattah 1989).

Sceletium spp. have been shown to contain highest alkaloid levels in woody stems, followed by [in decreasing order] roots, green stems and leaves (Smith, M.T. et al. 1998).

Trichodiadema bulbosum has been reported to contain an 'intoxicating' alkaloid, possibly *mesembrine* (Watt & Breyer-Brandwijk 1932), though in an alkaloid screening the plant tested negative (Steyn 1934).

A sample of 'kougoed', probably consisting of either S. anatomicum, S. expansum or S. tortuosum, yielded 0.7% *mesembrine* and 0.2% mesembrenone; 1-1.5% total alkaloids were found (Popelak & Lettenbauer 1967). In samples prepared either by crushing and immediate drying, or the fermentation method, the levels of mesembrenone were doubled, *mesembrine* levels were halved, and 4'-O-demethylmesembranol levels were much reduced. It would seem, then, mesembrenone would be a major active component of kougoed (Smith, M.T. et al. 1998).

Drosanthemum floribundum, Glottiphyllum linguiforme [M. linguiforme], G. longum var. longum, Lampranthus deltoides, L. glomeratus [M. glomeratum], L. scabrum [M. scabrum], Mestoklema tuberosum, Nycteranthus splendens [M. splendens], N. umbelliflorus [M. umbelliflorum], Oscularia caulescens [M. caulescens][traces], O. deltoides, Prenia relaxata [M. relaxatum], Ruschia congesta [M. congestum], R. lineolata, R. multiflora [M. multiflorum], R. rubicaulis [M. heteropetalum, M. rubricaule][traces], R. tumidula [M. tumidulum] (Jeffs 1981; Steyn 1934), Tetragonia expansa (Webb 1949), Trichodiadema barbatum [M. barbatum] (Festi & Samorini 1995) and T. intonsum [M. intonsum] contain alkaloids which were not identified (Jeffs 1981; Smith, M.T. et al. 1998; Steyn 1934). See also **Delosperma** and **Nananthus**.

Sceletium expansum is a slightly succulent decumbent or scrambling herb or subshrub; stem diffuse; branches lax, slender, reflexed, 15-30cm long, often robust with age and erect, weakly lignified; bladder cell idioblasts small. Leaves weakly succulent, connate, not imbricate, flat, apex recurved, much-spreading, broad-lanceolate, acute, base attenuate, flat, keeled by the prominent middle nerve, rather glittering, subcarinate, papulose, marcescent, nerves and veins persistent, 2.5-3.8(-6.5)cm x 5-10mm, with +- straight secondary veins parallel to midvein, when young thickish, green, minutely papillate, when old marcescent and membranaceous, dried nerves persistent. Flowers large, bigeminate, ternate or bitternate in a terminal, elongated, thick peduncle, pale yellow, c.4cm diam.; pedicels 5-10mm long, bracteated; tepals 5; calyx 5-cleft, three of the lobes very large, two subulate, calyx tube adnate with ovary; petals very numerous, linear, as long as the longer calyx lobes, pale yellowish; stamens innumerable, in many rows united at base; petaloid staminodes to 2mm broad, emarginate, filamentous staminodes concealing stamens and stigmas. Ovary (4-)5(-20)-celled; stigmas 4-5, obtuse, to 2mm long; styles 5, short. Fruit c.1cm diam., 5-locular, many-celled, dehiscing in a star-like manner at summit, valve wings present; seeds many, brown, crested.

Karroid areas in wetter parts of Western Cape Province [S. Africa] from Malmesbury to Clanwilliam (Gerbaulet 1996; Harvey & Sonder 1984).

S. tortuosum and S. strictum are becoming rare in the wild due to over-harvesting.

Cultivate from seed in sterile seed-raising mix and humidity chamber; seeds are germinated in the same manner as cactus seeds. May also be grown from cuttings. Plants require good sunlight, dry air, and well-drained soil. Water frequently, allowing to dry out between waterings; water less in dormancy. Does not like excess nitrogen; tolerates temperatures as low as 5ºC (Festi & Samorini 1995). S. anatomicum enjoys lots of phosphate and potassium, and in periods of active growth, regular watering, without allowing the soil to dry out between waterings (theobromus pers. comm.).

Carpobrotus edulis is a prostrate subshrub with several long, branched, trailing stems to 2m long, 8-13mm thick, at length woody, angles +- marginate, rooting at the nodes; flowering branches 3-8 noded with elongated, ancipitous, +- 2-winged internodes 1-5cm long, the penultimate one to 13mm thick, lower ones c.5mm thick. Leaves very succulent, opposite, sessile, acutely triquetrous, dull green, glabrous, slightly incurved, gradually acute from the middle, in profile the keel +- parallel with edges and shortly upturned to apex, mostly as thick as wide, thicker near tip, all faces slightly concave, keel permanently serrulate (at least in upper part), most 4-8cm long, 8-17mm wide, 8-15mm thick. Flowers 7-8.5cm diam., pedicellate; pedicel slightly compressed, 10-20mm long, ancipitous, with acute serrulate edges; calyx tube turbinate or oblong-turbinate, or with convex edges, passing gradually into pedicel, slightly compressed, edges acute, serrulate-crenulate, (15-)20-25mm long and wide, (13-)17-22mm thick; sepals 5, the 2 longest 20-45mm long with serrulate keels, others short with leafy green points, densely dotted almost to edge of membranous margins; petals c.120-130, 3-5-seriate, yellow at first, later flesh-pink and becoming nearly white at base, obtuse to +- acute in outline, 30-35 x 1.5-2.5mm, densely streaked throughout when dry; stamens c.400-600, c.6-7-seriate, filaments 3.5-7mm long; anthers yellow, 1.8-3.5mm long. Ovary convex at apex with a central depression, becoming depressed in fruit; styles 8-10, 7-15mm long. Fruit dull yellowish, pedicellate, nearly hemispherical to subglobose or obovoid, slightly compressed, depressed on top, c.2.5-3cm long, 2.5-3.5cm wide and thick; seeds obovate-lenticular, nearly symmetrical, 1.15-1.55mm long, 0.7-1.05mm wide.

S. Africa [coastal regions of Cape Province and Natal]; grown as a sand-binder and ornamental in s. Europe, US [California] and Australia [coastal regions in WA, SA, Vic., NSW and Tas.] (Blake 1969).

Very similar to C. rossii (pers. obs.), which is distinguished by the keel of the leaf and larger sepals being mostly smooth, and by its light purple or deep pink petals, which later fade (Blake 1969).

SCHISANDRA [Schizandra]

(Schisandraceae/Magnoliaceae)

Schisandra chinensis *(Turcz.) Baill.* **(Kadsura chinensis** *Turcz.***; Maximowiczia chinensis** *(Turcz.) Rupr.***)** – wu wei zi, wu wei dze, wu wei tzu, pei wu wei tzu, fruit of five flavours, magnolia vine

Schisandra sphenanthera *Rehder et E.H. Wilson* **(Kadsura peltigera** *Rehder et E.H. Wilson***)** – nan wu wei tzu, nan wu wei zi ['southern five flavour fruit']

The dried berries of S. chinensis [and the less often used S. sphenanthera] are a prized tonic stimulant in TCM, with many medicinal virtues. They are considered to have a sour and warm energy, with an affinity for the kidneys and lungs – their wide array of effects is believed to be due to possessing all five flavours or energies of TCM. The berries are tonic, adaptogenic, rejuvenative, aphrodisiac, CNS-stimulant, respiratory stimulant, astringent, antitussive, demulcent and antidiarrhoeic, as well as improving mental function and learning skills, promoting a sense of well-being, increasing stamina, stimulating the immune system, improving oxygen absorption, promoting semen production, slowing aging, stabilising blood pressure and controlling perspiration. They can improve the sensitivity of vision and hearing, enlarge the visual field, and increase the speed of adaptation to dark. Goldi hunters once chewed the berries to

strengthen themselves on sable hunts, sometimes taking only a handful of the berries and no other provisions. Although chewing several of the pungent-tasting dried berries at a time is the best method of consumption, they may also be decocted in a dose of 2-6g (Bone 1996; Bremness 1994; Halstead & Hood 1984; Hsu et al. 1986; Huang 1993; Komarov & Shishkin ed. 1985b; Reid 1995).

The flesh of S. chinensis berries contains high levels of sugars as well as citric acid, ascorbic acid [vitamin C], tartaric acid, malic acid, fumaric acid, sorbic acid and protocatechuic acid; the inner seed coat contains a large amount of essential oil [with *citral*, β-chamigrene and β-chamigrenol]. Essential oil content is higher in spring [0.6%] than in autumn [0.2%]. Berries also yield vitamin E, triterpenic acids, triterpene lactones, and up to 4.19% lignans – such as schizandrin, schizandrin B, deoxyschizandrin, γ-schizandrin, schizandrol, gomisins A-T, wuweizisu C, 6-O-benzoylgomisin O, sesquicarene and 5-OH-methyl-2-formaldehyde. The lignans have CNS-depressant activity, but the total extract acts as a stimulant. The fruit antagonises the respiratory depressant activites of *morphine*, and the central convulsant effects of *caffeine*, as well as potentiating the stimulation caused by *strychnine*. It also has synergy with **Eleutherococcus** (Bone 1996; Brekhman & Dardymov 1969b; Bruneton 1995; Chen et al. 1994; Halstead & Hood 1984; Hsu et al. 1986; Huang 1993; Senov 1940; Slanina et al. 1997). S. sphenanthera berries are less effective as a tonic and nutrient, but are still effective in relieving coughs (Bensky & Gamble 1993).

Schisandra chinensis is a liana with woody stems, climbing to 8m; bark rugose, dark brown; branches ascending, often winding around main stem, young stems flexuous with smooth, yellowish bark. Leaves elliptic, obovate or obovate-elliptic, c.10 x 5cm, cuneate, gradually tapering to the apex, with few, often obscure teeth, somewhat fleshy, slightly hairy beneath along veins, dark green, often with red petioles and prominent midribs beneath; petioles c.3cm. Pedicels 1-4cm, slender, pendulous; flowers dioecious, c.2cm diam.; perianth petaloid, white, wax-like, with a pleasant aroma, sometimes becoming pink before the end of flowering; tepals 6-9, the outer drooping, the inner convergent, oval-oblong, obtuse, often narrower than the outer; staminate flowers with 5 unusually short filamented stamens fused into a short, stout column; antherous column half as long as perianth. Pistillate flowers with very short-pedicelled, subcylindrical receptacle, densely covered with pistils; pistils numerous, rounded, with short style and crest, becoming dark red after ripening; ovary 2-celled; stigma oblique, stout, broad, with 2 narrow crests inside the margin; ovules 2 in each cell, pendulous. Fruit globular or obpyriform; during ripening, the fruiting receptacle elongates up to 50 times, causing the aggregate fruit produced from one flower to appear like an erect, unbranched raceme densely covered with red, globular berries; seeds reniform, surface verruculose. Fl. May-Jun.; fr. Sep. [though some of the chemical studies above suggest that it fruits beyond this range].

In mixed forests, particularly forest margins, streams and brooks, sometimes on unbroken steppes, and coastal forests confined to sandy soil – also in clearings where trees have been felled, and frequently climbing on trees; Japan, China, Siberia (Komarov & Shishkin ed. 1985b).

SCHUMANNIOPHYTON

(Rubiaceae)

Schumanniophyton klaineanum *Pierre ex A. Chev.* **(S. magnificum** *(K. Schum.) Harms***; Tetrastigma magnificum** *K. Schum.***; Randia immanifolia** *Wernham***)** – mgba mmiri, waka, akpuko ozò ['skin of the ape'], titimoto

Schumanniophyton problematicum *(A. Chev.) Aubrév.* **(Assidora problematica** *A. Chev.***)**

The bark of S. klaineanum is used by some natives of Gabon and Congo for its psychotropic properties. It is also considered a 'fetish' plant in Congo. The bark is chewed in small amounts as a stimulant to prevent unwanted sleep, but in higher doses it is said to act as a powerful aphrodisiac, with some harmful side-effects if taken frequently. In Congo, the bark is also macerated in palm wine, and taken with a ripe banana [see **Musa**] (Burkill 1985-1997; Watt 1967). In east Nigeria, it is used to treat insanity (Okogun et al. 1983). S. klaineanum bark, as well as that of S. arboreum, has been used as a stimulant for travellers and hunting dogs. The bark is also used to stupefy fish, as well as being eaten with fish and other meat, for obscure reasons (Usher 1974). In Nigeria, S. problematicum root is used by healers in treatment of insanity and agitated psychosis. Preliminary tests in mice of the ethanolic root extract [i.p.] showed effects such as sedation, nervous depression, hypothermia and decreased rate of respiration (Amadi et al. 1991).

S. klaineanum bark and root have yielded up to 1% alkaloids, with 0.3% found in the leaves; the root also contains a small amount of saponins, which are also found in the leaf, with tannins (Burkill 1985-1997); root bark yielded 0.0075-0.03% schumannificine, 0.0125-0.042% N-methylschumannificine, 0.0054% anhydroschumannificine, 0.0075% N-methylanhydroschumannificine, 0.021% schumanniophytine, 0.03% isoschumanniophytine and 0.036-0.0375% noreugenin [5,7-dihydroxy-2-methylchromone] (Houghton & Hairong 1985; Okogun et al. 1983).

S. problematicum root bark [harv. late Jun., Amitiora] yielded 0.175% of a crystalline mixture, which contained [as % of root bark] 0.03% schumanniophytine [a new pyridine alkaloid] and *scopoletin* combined; the remaining extract gave 0.00175% and 0.00035% each of 2 new piperidines, as well as noreugenin, and further yields of *scopoletin* and schumanniophytine. Stem and leaf gave positive tests for the presence of alkaloids (Schlittler & Spitaler 1978). An extract of the root had an LD50 of 2.37g/kg [i.p.] in mice (Amadi et al. 1991).

Schumanniophyton klaineanum is a shrub or small tree 3.6-4.9m tall, with soft-wooded stems. Leaves usually opposite, very large, sessile with lamina cuneate to the base, elongate-obovate, 60-120 x 30-45cm, with c.30 pairs of lateral nerves, minutely pubescent on nerves beneath. Flowers white or yellow, sessile, in a dense cluster subtended by broad bracts and borne at ends of shoots opposite a single leaf and just above a pair of leaves; calyx adnate to ovary; corolla tube 6-7cm long, densely tomentellous, lobes 7-10, narrowly lanceolate, contorted (rarely imbricate), overlapping to the left, 2cm long; stamens epipetalous, as many as petals, and alternating with them, included; anthers 2-celled. Ovary 3-4 celled; ovules numerous in each cell, placentation axile; style head 4-6-lobed. Fruit indehiscent; seeds not winged.

In forest; s. Nigeria, Cameroon, Gabon and Cabinda (Hutchinson & Dalziel 1954-1972).

SCIRPUS

(Cyperaceae)

Scirpus sp. – bakana, bakánoa, bakánawa, bulrush

An unidentified Scirpus sp., known as 'bakana', is a feared and respected shamanic plant among the Tarahumara of Mexico. The root tubers ['bolitas'] are first sung to, and offered food, before being ingested. They are eaten or rubbed on the body to induce a deep sleep-like state, in which the shaman experiences brilliantly coloured visions, travels over large distances in other realms, and communicates with spirits of the dead. It is said caution must be taken when ingesting this plant, as it can make one 'jump into fires'. If the plant is mistreated in any way, it is said to cause the person responsible to become sick and even die. Paradoxically, the Tarahumara see the plant as a protector of the mentally ill, able to cure insanity, yet it is considered that anyone who cultivates it will become insane, due to the sound the plants are said to make. The Tarahumara who use it will instead either buy it from mestizos who cultivate it, or travel to where it grows to collect it. The plant is also credited with analgesic properties (Bye 1979b; Diaz 1979; Pendell 1995; Schultes & Hofmann 1980).

The Cherokee use the related S. validus ['great bulrush'] as an emetic (Hamel & Chiltoskey 1975). In India, S. articulatus root is used as a mild purgative, though the roots of S. grossus taken in milk are used as a nourishing beverage for those suffering from diarrhoea and/or vomiting. The root may also be chewed to allay sickness and mask bad-tasting medicines. S. tuberosa bears edible tubers known as 'water chestnuts' or 'ground chestnuts' (Nadkarni 1976). In Nepal, seeds of S. kysoor ['kaancho laae'] are used in ritual incense, but not by the Kirati (Müller-Ebeling et al. 2002). S. maritimus rhizomes have been used in China as an astringent and diuretic (Powell et al. 1987).

Alkaloids of the β-carboline type have been detected in an unspecified Scirpus sp. (Diaz 1979), yet the species used by the Tarahumara has not been chemically analysed, and its pharmacology is still unknown.

S. maritimus [whole plant] has been reported to contain an alkaloid (Hultin & Torssell 1965); the seeds have yielded stilbenes [piceatannol, resveratrol, scirpusin A and scirpusin B] and ε-viniferin. The scirpusins have also been found in S. fluviatilis rhizomes (Powell et al. 1987).

Scirpus atrovirens is a caespitose perennial sedge grass; stems erect, jointed, slender or stout, to 1.5m. Leaves broadly linear, grass-like, with membranous ligule; principal blades to 18mm wide, mostly on lower half of stem. Inflorescence a terminal panicle with many rays, once or usually twice branched, subtended by leaf- or bristle-like bracts; spikelets stalked or in clusters on rays, ovoid or short-cylindric, 2-8mm long, densely crowned in subglobose glomerules; flowers hermaphrodite, minute, spirally arranged, subtended by a scale-like bract (glume); scales broadly elliptic or obovate, the body obtuse or acute, pale midvein prolonged into a conspicuous mucro usually 0.5-0.8mm long; sepals and petals represented by 6 rough bristles; stamens 3; style 3-branched. Fruit a nut, smooth, very pale to white, compressed-trigonous, obovate, 0.8-1.2mm; bristles pale and inconspicuous, straight or nearly so, shorter to barely longer than the achene, or rudimentary, or lacking.

Damp, preferably acidic soils in light woodland, bogs and shallow water; N. America (Darke ed. 1994). This species was depicted by Schultes & Hofmann (1992) as a representative of the genus, which has produced some confusion as it was unclear whether they were suggesting it as a possible identity for the Tarahumara 'bakana'.

SCOPOLIA

(Solanaceae)

Scopolia carniolica *Jacq.* **(S. hladnikiana** *Nyman***; S. viridiflora** *Frey. ex Koch***; Scopolina atropoides** *Schult.***; Sc. hladnikiana** *W.D.J. Koch***; Hyoscyamus scopolia** *L.***)** – scopolia, krainer tollkraut
Scopolia carniolicoides *Wu et Chen* **(Anisodus carniolicoides** *(Wu et Chen) D'Arcy et Zhang***)**
Scopolia caucasica *Kolesn. ex Kreyer*
Scopolia japonica *Maxim.* – làng dàng, lang tang
Scopolia lurida *(Link) Dunal* **(S. anomala** *(Link et Otto) Airy-Shaw***; S. mairei** *H. Lév.***; S. stramonifolia** *(Wall.) N.P. Balakr.***; Anisodus fischerianus** *Pascher***; A. luridus** *Link***; A. mairei** *(H. Lév.) Wu et Chen***; A. stramonifolius** *(Sweet) G. Don***; Nicandra anomala** *Link et Otto***; Physalis stramonifolia** *Wall.***; Whitleya stramonifolia** *(Wall.) Sweet***)** – Himalayan scopolia, lurid scopolia, ghanti phul, vangale, langdang
Scopolia sinensis *Hemsl.* **(Atropanthe sinensis** *(Hemsl.) Pascher***)**
Scopolia tangutica *Maxim* **(Anisodus tanguticus** *(Maxim) Pascher***)** – zang qie, san long zhi, yellow anisodus

S. carniolica root is used in extraction of tropane alkaloids for the European pharmaceutical industry, and is sometimes used as an adulterant or substitute for deadly nightshade [see **Atropa**] or mandrake root [see **Mandragora**]. It has been suggested that the herb may have been an ingredient in mediaeval witches potions and salves [see *Methods of Ingestion*]. It was reputedly used in Alpine areas as a poison, and to make magical drinks. Its CNS effects are considered to be +- narcotic [probably more accurately described as hallucinogenic in high enough doses], and have been compared to the effects of henbane [see **Hyoscyamus**]. S. carniolicoides is used medicinally in China, as is the root ['san long zhi' or 'shan lang dong'] of S. tangutica, which is used as an analgesic and anticonvulsant, treating conditions of shock and potentiating the action of barbiturates. S japonica is used medicinally in Japan and Korea (D'Arcy ed. 1986; Festi 1996; Hawkes et al. ed. 1979; Huang 1993; Rätsch 1990, 1992; Usher 1974). During the 'Black Mountain Campaign' in Nepal, S. lurida was mistaken for an edible plant by Gurkhas, who ate it and suffered an intoxication similar to that produced by deadly nightshade (Chopra et al. 1965). In Nepal, roasted seeds have sometimes been eaten in 'dhal' [a lentil dish] by Kirati shamans, for the purpose of shamanic travel (Müller-Ebeling et al. 2002).

S. carniolica [whole plant] has yielded 0.45-0.55% alkaloids, consisting of *hyoscyamine*, *hyoscine*, tropine, solanidine, scopine, cuscohygrine [bellaridine], *scopoletin* and methylesculetin; roots yielded 0.43-0.51% alkaloids, consisting mainly of *hyoscine* and *hyoscyamine*, as well as pseudotropine and 3-α-tigloyloxytropane (An-ming & Zhi-yu 1986; Festi 1996; Gheorghiu et al. 1961; Henry 1939; Schermerhorn et al. ed. 1957-1974; Willaman & Li 1970).

S. caucasica roots and rhizomes contain *hyoscine*, *hyoscyamine* and *atropine* (Willaman & Li 1970).

S. japonica leaves have yielded 0.18% alkaloids, mostly *hyoscyamine*, as well as *hyoscine*, nor-*hyoscyamine*, *atropine*, scopoleine, *scopoletin*, scopolin, methylesculin, rotoin, dimethylamine and *choline*; roots also contain solanine [see **Solanum**] (Henry 1939; Schermerhorn et al. ed. 1957-1974).

S. lurida was found to contain *hyoscine*, *atropine*, tropine and cuscohygrine in the whole plant; root also contained *hyoscyamine*, and scopine was found in all parts except the root (Willaman & Li 1970). As S. anomala, roots have yielded 1.09-2.8% alkaloids, of which c.18% was *hyoscine*, as well as *hyoscyamine* and cuscohygrine. Aerial parts contained tropanes in similar concentrations, though cuscohygrine was not present (Chopra et al. 1965; Skymanska 1988).

S. sinensis has yielded *hyoscine*, nor-*hyoscine* (Ripperger 1995), *hyoscyamine*, anisodamine, anisodine and cuscohygrine (An-ming & Zhi-yu 1986).

S. tangutica root has yielded up to 2.63% alkaloids during flowering, and 2.93% from aerial parts harvested at the same time; at the beginning of flowering, 2-year old plants yielded 1.73% alkaloids from leaves, 0.58% from stems, and 0.587% from roots; others reported yields from 2-year old plants harvested in the beginning of July – 1.22% from roots, 1.5% from leaves, and 0.49% from stems. The major alkaloids are *hyoscine*, *hyoscyamine* and *atropine*; these tropanes comprise [during flowering] 83% of total leaf alkaloids, 87% of total stem alkaloids and 47% of total root alkaloids; anisodine and anisodamine are also present. Levels of the tropane alkaloids are higher in older plants (Alexandrowa 1961; Huang 1993; Semenova 1954; Sokolov & Aleksandrowa 1964).

Scopolia carniolica is a glabrous, perennial herb with a fleshy, horizontal rhizome; stems 20-60cm tall, simple or branched above. Leaves alternate, simple; lower leaves scale-like, oblong-spathulate; upper leaves to 20 x 8cm, elliptical to ovate or obovate, somewhat acuminate, cuneate at base, entire, petiolate. Flowers solitary in leaf axils; pedicels 2-4cm, filiform, nodding; calyx c.1cm, campanulate, shallowly 5-lobed, accrescent; corolla cylindrical to campanulate, 1.5-2.5cm, shallowly 5-lobed, lobes convolute in bud, dark brownish-violet outside, yellowish to brownish-green within; stamens 5, included, inserted at base of corolla. Ovary superior, 2-locular; style simple; stigma capitate, entire to 2-lobed; fruiting calyx tightly including fruit. Fruit a circumsessile capsule, surrounded by calyx, c.1cm diam., globose.

Ravines, moist broadleaf forests, especially beech; central and s.e. Europe, extending to Italy, c. Ukraine and Lithuania; rare.

Sow seed in trays in spring, later transplanting stout seedlings to a fertile position, partially shaded (Festi 1996; Hawkes et al. ed. 1979; Tutin et al. ed. 1964-1980).

SCUTELLARIA

(Labiatae/Lamiaceae)

Scutellaria alpina *L.* – alpine skullcap
Scutellaria baicalensis *Georgi.* **(S. grandiflora** *Adams***; S. lanceolaria** *Miq.***; S. macrantha** *Fisch.***)** – huang-qin, Chinese skullcap, baical skullcap
Scutellaria galericulata *L.* – marsh skullcap, river skullcap
Scutellaria indica *L.* – tatsu-nami-so
Scutellaria lateriflora *L.* – Virginian skullcap, Quaker bonnet, helmet flower, blue pimpernel, mad dog weed
Scutellaria nana *A. Gray* – dwarf skullcap, desert skullcap, mad dog skullcap
Scutellaria racemosa *Pers.* **(S. bonariensis** *Willd. ex Benth.***; S. hastata** *Larrañaga***; S. heterophylla** *Willd. ex Benth.***; S. rojasii** *Briq.***; S. rumicifolia** *Kunth***)** – chayuts, contento, alegria
Scutellaria spp. – skullcap, scullcap

In Ayurvedic medicine, Scutellaria spp. are used to treat insomnia, neurosis, nervous tension, tremors, incontinence and arthritis. Combined with **Centella** asiatica [1tsp of each, infused], they may be taken to improve awareness and promote perception. Combined with **Withania** somnifera [1:4], they are used as a nerve tonic (Frawley & Lad 1986). In magical practices, skullcap is used in spells for relaxation and peace, and for visualisation in psychic dream-work; it has also been used in potions for tantric sex magic (Cunningham 1994; Tierra 1988).

In Cauca, Colombia, indigenous inhabitants consider S. racemosa a magical herb. Paez shamans there chew it during divinatory sessions to control the experience and reduce its intensity if necessary. Likewise, the fresh herb is often chewed to balance the stimulant action of 'coca' leaves [see **Erythroxylum**]. The best samples are often traded amongst Paez shamans for coca leaves from the lower, sub-tropical zones (Antonil 1978).

In North America, S. lateriflora has long had a reputation for treating epilepsy and rabies (Polunin & Robbins 1992). It acts as a calming sedative, antispasmodic and nerve tonic, and is used by herbalists to treat anxiety, depression, stress, fatigue, pre-menstrual tension, rheumatic pain,

neuralgia and severe hiccoughs. Its bitterness is also strengthening and stimulating to the digestive system. It has shown some potential in easing the pain of multiple sclerosis, as well as reducing withdrawal symptoms from barbiturates and alcohol. Commercial skullcap [referring to S. lateriflora] may sometimes be adulterated with 'germander' [Teucrium spp. – see *Endnotes*]. In TCM 'huang qin', the dried root of S. baicalensis [may be substituted with S. amoena, S. ikoninkovii or S. viscidula], is used to treat respiratory tract and bacterial gastrointestinal infections. It has sedative, antihypertensive, antiinflammatory, antibacterial, diuretic, vasodilatory and antiallergic properties (Bremness 1988, 1994; Fraser 1995; Huang 1993; Hutchens 1973, 1992; Mabey et al. ed. 1990; Tierra 1988).

S. lateriflora can be infused into a tea [which is very bitter], and is quite effective when smoked; sublingual usage is also effective. Many species produce an experience somewhat similar to that felt with many **Salvia** spp., probably due to their content of neo-clerodane diterpenoids, which appears to be +- generic (pers. obs.). S. galericulata, which grows across the northern temperate zones, has sedative properties, and has been suspected of poisoning stock animals (Pammel 1911). When smoked, the leaves have been observed to give much stronger psychotropic effects than does S. lateriflora; the effects have been compared to good quality **Cannabis** leaf. S. nana has been found to be even stronger, reputedly comparable to good quality **Cannabis** flower buds, though "it will cloud your head and make you tired" (Brounstein 1995; friendly pers. comm.). S. indica is also claimed to be psychoactive (Simon pers. comm.). An experiment with smoking a small aged sample of S. indica var. parvifolia leaves was inconclusive, further investigation so far hindered by lack of material. S. alpina herbage is also psychotropic when smoked in small amounts. Another species, awaiting proper identification, has proven to be moderately and pleasantly psychoactive when smoked. Like some of the **Salvia** spp., the flowers of this species seem to be more potent than the leaves, and both synergise well with **Psilocybe** mushrooms (pers. obs.). This species is sometimes sold in Australian nurseries labelled as either S. indica or S. formosa. After submitting a flowering sample to the Royal Melbourne Botanic Gardens for identification, I was told that it was neither species. These gardens have several specimens of this Scutellaria sp. in their collection labelled as S. indica, and the incorrect labelling has still not been changed at the time of writing. This plant seems to bear some affinity to published descriptions of S. formosana *N.E. Brown*, though without fully fitting the descriptions.

S. adenostegia shoots have yielded *apigenin* and chrysin [see **Passiflora**]; roots yielded chrysin, 2'-MeO-chrysin, baicalein, 5,2',6'-trihydroxy-6,7,8-trimethoxyflavone and 5,2',6'-trihydroxy-7,8-dimethoxyflavone (Chemesova et al. 1995).

S. baicalensis has yielded the neo-clerodane diterpenoids scutebaicalin [0.018%, presumably w/w], baicalin, baicalein and 7-MeO-baicalein; the flavonoids wogonin [5,7-dihydroxy-8-MeO-flavone; anxiolytic, BZ-receptor agonist in *GABA*-A complexes], 7-MeO-norwogonin, wogonoside, skullcapflavones I & II (Esquivel et al. 1997; Huang 1993; Hui et al. 2003; Hussein et al. 1996), oroxylin A [5,7-dihydroxy-6-MeO-flavone; selective BZ-receptor antagonist] and 5,7,2'-trihydroxy-6,8-dimethoxyflavone [anxiolytic, non-sedative BZ-receptor agonist] (Huen et al. 2003a, 2003b); and *melatonin* [0.0007%] (Murch et al. 1997). The water extract of the root has anticonvulsant activity, and has an affinity for BZ receptors (Wanga et al. 2000).

S. columnae has yielded the neo-clerodane diterpenoids 11-epi-scutecyprin [0.0066%] and scutegalin D [0.0058%] (Malakov & Papanov 1997).

S. drummondii has yielded the neo-clerodane diterpenoid scutedrummonin (Esquivel et al. 1997).

S. indica has yielded scutelarin (Nadkarni 1976).

S. lateriflora has yielded the neo-clerodane diterpenoids scutelarins A, B & C, ajugapitin and scutecyprol A (Bruno et al. 1998), as well as *melatonin* [0.000009%] (Murch et al. 1997), flavonoid glycosides, iridoids, volatile oil and tannin (Polunin & Robbins 1992); epicuticular wax contains n-tritriacontane, n-pentatriacontane, n-hentriacontane and other alkanes (Yaghmai & Khayat 1988).

S. orientalis ssp. pinnatifida has yielded the neo-clerodane diterpenoids scutorientalins A, B [0.0057%], C, D [0.01%] and E [0.018%] (Malakov & Papanov 1996; Malakov et al. 1997).

S. polydon has yielded the neo-clerodane diterpenoids scupolins A-I [0.064% total], jodrellin B [0.0025%] and scutecolumnin A [0.0003%] (De la Torre et al. 1997).

S. pontica has yielded the neo-clerodane diterpenoids scupontins A [0.042%], B [0.0012%], C [0.014%], D [0.084%], E [0.002%], F [0.0048%] and G [0.002%], scutalbin A and scutalpin M (Rodriguez et al. 1997).

S. rivularis aerial parts yielded the neo-clerodane diterpenoid scutellone A (Lin et al. 1987).

S. seleriana has yielded the neo-clerodane diterpenoid scuteselerin [0.001%] and the flavone oroxylin A (Esquivel et al. 1997).

Scutellaria indica is a perennial herb spreading by creeping rhizomes; stems erect, 20-40cm long, prominently white-pilose. Leaves loosely few-paired, deltoid-cordate to broadly ovate, obtuse, cordate at base, obtusely toothed, spreading-hairy, often prominently pubescent on both sides, minutely uneven on surface, upper leaves sometimes orbicular, 1-2.5cm diam.; internodes longer than leaves; petioles 5-20mm long. Inflorescence a terminal spike 3-8cm long, with prominent spreading hairs; flowers paired in verticils; calyx campanulate, bilabiate, c.3mm long in anthesis, 6-7mm long in fruit; corolla 18-22mm long, geniculate at base, becoming erect above, pale purple, limb bilabiate, upper lip erect, galeate, lower lip spreading; stamens 4, under upper lip of corolla; anthers approximate in pairs, lower ones +- reduced and unilocular. Ovary 4-lobed. Nutlets orbicular, slightly compressed, c.1mm long, densely mammillate. Fl. May-Jun.

Common on sunny hills; Korea, China, Indochina, Formosa, Ryukyus, Japan [Honshu, Shikoku, Kyushu].

S. indica var. parvifolia [S. parvifolia, S. indica var. japonica] is differentiated by its shorter stems (5-20cm long), and smaller leaves (c.1cm long and wide) with margins toothed more sparsely.

S. indica var. tsusimensis [S. tsusimensis] is a larger plant (10-30cm tall), with leaves 2-4cm long and wide, shallowly cordate to truncate at base, with impressed nerves above (Ohwi 1965).

SECURIDACA

(Polygalaceae)

Securidaca longipedunculata *Fresen* **(S. longepedunculata** *Fres.***; S. longepedunculata** *Hochst.***; Lophostylis angustifolia** *Hochst.***; L. oblongifolia** *Hochst.***)** – violet tree, Rhode's violet, wild wisteria, Senegal-root tree, fibre tree, tchúnfki, foudara, foudaraye, diouto, fouf, bwazi, mpesu, chwehweha, ipeta, arbre à serpent

The roots of this plant [as 'tchúnfki'], collected in winter or in the dry season, are prepared into an aqueous infusion by the Balanta of Guinea-Bissau in w. Africa. The drink thus made is important in religious rites, due to its supposed entheogenic effects (Costa et al. 1992a).

In Zimbabwe and Malawi, a root infusion is applied as a body wash to 'arouse spirits' (De Smet 1998). The plant is used by the !Kung of South Africa in healing ceremonies. Also in S. Africa, the Chopi take it mixed with Sphedamnocarpus pruriens [Malpighiaceae] to treat people possessed by spirits [see *Endnotes*]. Conversely, the roots are snuffed in the Nsanje district of Malawi [mixed with Annona senegalensis, Asparagus africanus and Chenopodium ambrosioides – see *Endnotes*] to induce spirit possession. Another composite snuff containing S. longipedunculata is discussed under **Piper 1**. In Gambia, a root decoction is used to relieve fatigue, and smoke from the smouldering bark is inhaled to relieve dizziness. In Senegal, the root is powdered and snuffed to keep awake at night; it also treats migraine used in this manner. However, the powdered root extract is known to cause 'violent sneezing'. In s. Nigeria, the seeds are snuffed for the same effect, as well as to treat rheumatism. The seeds are rich in a toxic, purgative oil, which is used as an antidote to Strophanthus spp. arrow-poison, and snake-bite. Leaves have also been decocted to treat poisoning, due to their purgative action. A leaf wash is used to bathe the eyes after attack by a spitting-cobra [see **Naja**, **Ophiophagus**]. In Nigeria and Tanganyika, the plant is used as an anticonvulsant for children, and in S. Africa as an aphrodisiac and bronchitis treatment. A root decoction has sedative actions, and may result in several hours of sleep. The roots are also generally considered toxic, and purgative in small amounts, and have been used for homicidal or suicidal means. Women sometimes take them vaginally to commit suicide, though death is slow by such means, often taking up to 2 weeks to eventuate. It is claimed that the inner root-bark is only purgative, whereas the rest of the root is toxic. The bark can also cause blindness if brought into contact with the eyes (Burkill 1985-1997; Olajide et al. 1998; Samorini 1996b). As unspecified parts of the plant have been used as an ordeal poison applied to the eyes, with ocular damage signifying guilt, the chances of a charge of innocence could be slim indeed. The bark and roots have also been used internally as ordeal poisons (De Smet 1998).

Fresh roots have been described as 'foul-smelling', and are used in huts to repel snakes and rodents; others report the fresh roots to have an odour of 'wintergreen' [see **Gaultheria**], a sweetish taste, and a numbing after-effect. In small amounts [1/6 tsp] the powdered root is taken with 5 other powdered plant roots in equal amounts [Cenchrus biflorus, Olax subscorpioidea, **Piper** guineense (see **Piper 1**), Psorospermum guineense and **Syzygium** aromaticum] as a common Nigerian preparation called 'gakini', which is used to treat asthma and respiratory disorders (Akah et al. 1997; Burkill 1985-1997; Costa et al. 1992a).

S. longipedunculata roots harvested in winter [in the dry season] yielded 1.45% [w/w] crude extract, containing ergoline alkaloids [*elymoclavine*, dehydroelymoclavine, 3 unidentified ergot alkaloids, and a new ergoline have been found]; roots harvested in the wet season have yielded cis- and trans-derivatives of cinnamonic acid, and no alkaloids (Costa et al. 1992a, 1992c, 1994; Samorini 1996b; Wrobel et al. 1997). Roots have also yielded aromatic constituents, such as valerianic ether, methylsalicylate

[c.0.1%], methyl 4-OH-benzoate [antimicrobial preservative], methyl 4-OH-3-MeO-benzoate [methyl vanillate], methyl 2,6-dihydroxybenzoate, phenyl 3-amino-5-nitrobenzoate, phenylmethyl 2-OH-benzoate [benzyl salicylate], methyl-2,6-dihydroxybenzoate [ingestion can cause nausea, vomiting, acidosis, pulmonary oedema and death], 4-bromophenyl 4-cyanobenzoate, N-diphenylene benzenamine, 4-(3-OH-prop-1-enyl)-2-MeO-phenol [coniferyl alcohol], 1,2-dihydrocyclobuta(b)-quinoline-4-carboxylic acid and 7,8,10-trimethylbenzo(g)pteridine-2,4-(3H,10H)-dione (Burkill 1985-1997; Costa et al. 1992b). Roots have also yielded glycosides of oleanic acid, which are thought to be responsible for the anticonvulsant effects of the roots (Burkill 1985-1997). Early tests showed the presence of saponins and starches in the root bark (Nihoul-Ghenne et al. 1967). A root extract was shown to increase sodium currents in rat skeletal muscle [cell culture], and has been hypothesised to interact with skeletal dihydropyridine receptors (Mouzoua et al. 1999). A methanol extract of the root [harv. Aug. 1996 from Aebokuta, Nigeria] showed analgesic, antiinflammatory, sedative and anticonvulsant effects in mice [given i.p.] (Olajide et al. 1998). Bark has been claimed to contain the alkaloid *securinine* (Buckingham et al. ed. 1994; Harborne & Baxter ed. 1993), though myself and colleagues have not been able to locate any primary reference to verify this.

This is the first time ergot alkaloids [see **Claviceps**] have been found outside of the fungi and the morning glories [Convolvulaceae – eg. see **Ipomoea**]. However, the roots in w. Africa are often parasitised by a mould, and it is uncertain at this stage whether this mould is the producer of the alkaloids (Samorini pers. comm.).

Securidaca longipedunculata is a shrub or small tree up to 6m tall; bark light grey, smooth, becoming yellowish to grey, finely scaly; branchlets inconspicuously softly pubescent, becoming glabrous. Leaves alternate, rarely opposite, oblong to linear-lanceolate or ovate-oblong, 2-5.5(-9)cm long, 0.5-2cm wide, coriaceous, glabrous above, glabrous or very minutely pubescent beneath, apex obtuse or rounded, base pointed; petiole 2-10mm long; stipules none. Inflorescence a terminal or axillary simple raceme to 15cm long; pedicel 1-1.8cm long, pubescent; flowers hermaphrodite, zygomorphic, purple, fragrant; bracts and bracteoles minute, lanceolate, deciduous; sepals 5, free, imbricate, posterior and anterior sepals 3-6 x 2.5-5mm, lateral sepals 2.7-9 x 8-9.5mm wide; petals 3, the lateral ones free from the abaxial (keel) one, upper 2 petals obovate, 5-6 x 2.5-4mm; stamens 8, filaments fused into a sheath 6-7mm long, split above, the free part 4mm long; anthers erect, 1-2-celled, opening by an apical pore. Ovary free, usually 2-celled; style simple, 8-10mm long; stigma 1.5-2mm long; ovules usually solitary in each cell, pendulous. Fruit smooth, rugulose, notched at base on side of aborted carpel, indehiscent, samaroid, 5-7cm long, wing 1.5-2cm broad, variable, sometimes with a very small second imperfect wing, ventral margin nearly straight or curved, gradually or abruptly narrowed with numerous curved, parallel, forking nerves; 1-seeded, seed 8 x 6mm. Fl. & fr. all year, though with less flowers in May-Jul. S. longipedunculata var. parvifolia flowers Sep.-Jan.

Widespread in savannah vegetation, sea level to c.1700m. S. longipedunculata var. longipedunculata has been recorded from Angola, Bennin, Burundi, Cameroon, Ethiopia, Gabon, French Guiana, Kenya, Malawi, Mali, Mozambique, Niger, Rwanda, Senegal, Sierra Leone, S. Africa, Sudan, Tanzania, Togo, Uganda, Upper Volta, Zaire and Zimbabwe; S. longipedunculata var. parvifolia has been recorded from Angola, Botswana, Malawi, Mozambique, Namibia, S. Africa, Tanzania, Zaire, Zambia and Zimbabwe. [Oddly, Guinea-Bissau was not listed amongst these reported occurrences.]

S. longipedunculata var. parvifolia [syn. S. longipedunculata var. parviflora, S. oblongifolia, S. spinosa] is differentiated by its young branches, which are transformed into leaf- and raceme-bearing spines; the young shoots are densely pubescent, whereas those of var. longipedunculata are only slightly pubescent (Hutchinson & Dalziel 1954-1972; Johnson 1987).

SENECIO

(Compositae/Asteraceae)

Senecio albo-lutescens *Schulz-Bipontinus* – peyote
Senecio calophyllus *Hemsley* – peyote
Senecio canicidus *Sessé et Moc.* – yerba de la puebla, ytzcuinpahtli ['dog medicine'], itzcuimpatli
Senecio cardiophyllus *Hemsley* – peyote
Senecio cervariaefolia *Schulz-Bipontinus* – peyote
Senecio elatus *Kunth* – hornamo amarillo
Senecio grayanus *Hemsley* – peyote, matrique
Senecio hartwegii *Benth.* – peyote de Tepic, sopépari
Senecio neomexicanus *A. Gray* **(S. blumeri** *Greene***; S. encelia** *Greene***; S. mutabilis** *Greene***; S. papagonius** *A. Nels.***; S. toumeyi** *Greene***; S. willowensis** *Greenm.***; Packera neomexicana** *Weber et Löve***)** – New Mexican groundsel, born for water's tobacco, tobaz iscini binat'oh
Senecio ovatifolius *Schulz-Bipontinus* – peyote
Senecio petasitis *DC.* – peyote
Senecio praecox *DC.* – peyote, palo loco ['crazy stick']
Senecio tephrosioides *Turz.* – hornamo amarillo
Senecio toluccanus *DC.* – peyote, guantlapatziinzintli
Senecio spp. – ragwort, groundsel, fireweed, squaw weed

The Tarahumara of Mexico refer to many of these species as 'peyote' [see **Lophophora**]. They are used medicinally, and in most cases it is unclear whether they have psychotropic effects. The Tarahumara use S. hartwegii in infusion as a purgative, and use the powdered plant as an insecticide. The leaves and roots are used to stupefy fish. S. canicidus is referred to in the Badianus Codex, Ramirez's Materia Medica of Mexico, and other works; it was used to relieve chest pains, and as a narcotic. It is reputed to be a convulsant in high doses, and is known today as a dog-poison. S. praecox, used in Mexico for wounds and rheumatism, is said to produce delirium. S. toluccanus has been used as a poison by sorcerers, to 'madden' their victims (Diaz 1979; Emboden 1979a; Pennington 1958; Salmón 1995; Schultes 1937a, 1937b).

In Peru, S. elatus or S. tephrosioides are sometimes added to brews prepared from the San Pedro cactus, **Trichocereus** pachanoi. S. elatus is said to be 'hallucinogenic' by itself, and aerial parts are also used as a potent ritual purgative (De Feo 2003; Ott 1993; Rätsch 1998). In n. Argentina, S. hieronymii stalks ['amaicha'] and/or S. bomanii stems ['cosillo blanco'] are sometimes used to prepare the alkaline reagent for chewing with coca [see **Erythroxylum**] (Hilgert 2001).

The Navajo smoke S. neomexicanus as an antidote to narcotics (Winter 1998). In Germany, S. vulgaris has been known as a witch's herb ['hexenkraut'] (De Vries 1991). In southern Africa, the Southern Sotho use S. asperulus as a charm to ward away bad dreams amongst their children; they also smoke the leaf of S. coronatus and S. erubescens with their tobacco [see **Nicotiana**], and decoct the root of S. dregeanus var. discoideus to treat madness and chest colds, also acting as an emetic. The juice from S. vulgaris is used to treat epilepsy. In Basutoland, S. coronatus is used as an ash with snuffing tobacco; in Transvaal, S. longiflorus is similarly used (Watt & Breyer-Brandwijk 1962).

Many Senecio spp. have long been associated with stock poisonings; they are toxic to the liver and can produce motor nerve paralysis, contractions of the uterus and digitalis-like cardiac activity, as well as emaciation (Keeler 1975; Watt & Breyer-Brandwijk 1962). Experiments with Senecio extracts from Mexican specimens were shown in humans and animals to produce excitation, and later irritability, followed by delirium. In the animal experiments, some became paralysed and later died (Emboden 1979a). Senecifoline nitrate, an alkaloid from S. latifolius, appears to be a 'hallucinogenic' CNS-excitant in cats [100-200mg/kg injected; route not given], though clonic convulsions, vomiting, extreme respiratory acceleration and pupil dilation were also observed. Symptoms subsided after about 2 hrs, though within the next week, the test animals lost appetite and gradually fell into stupor, dying 4-6 days after the injection. The smallest fatal dose tested was 16mg/kg. Post-mortem revealed lots of internal damage and does not make pretty reading! S. sylvaticus [harv. Aug., Yorkshire] and S. jacobaea [harv. Jun. & Aug., England] were non-toxic under the same conditions, though in Canada and New Zealand, this latter species is regarded as toxic to livestock (Cushny 1910/1911).

Senecio spp. contain alkaloids of a neurotoxic nature which, on alkaline hydrolysis, split into necine alkanolamines [which mostly have a pyrrolizidine ring] and necic acids. Other acids are formed on hydrolysis, which are similar to the necic acids, but are isoprene monoterpenes. A representative example is retrorsine, which on acid hydrolysis yields retronecine and retronecic acid. Senecio alkaloids are also considered to be carcinogenic. Sometimes, symptoms of poisoning from subtoxic doses do not develop for several weeks or more, consisting of appetite loss, exhaustion, abdominal pain and swelling, and progressive liver damage. In rats, extracts have produced mutations, and stock poisonings have resulted in debility and death (Cushny 1910/1911; Foster & Caras 1994; Henry 1939; Keeler 1975; Watt & Breyer-Brandwijk 1962). These plants, in general, should be regarded as too toxic for human experimentation unless proven otherwise, except for the exceptionally brave or foolhardy.

Senecio neomexicanus is an erect, herbaceous perennial, with 1 to several erect or ascending branches 15-60cm tall; rootstock stoutish. Herbage +- white-tomentose throughout, or sometimes stems and upper sides of leaves glabrate; stems finely striate under tomentum, often reddish-tinged. Leaves alternate; basal and lower leaves obovate to oblanceolate, 2-10 x 0.5-3cm, subentire to slightly lyrate, margins usually irregularly dentate, thick and firm in texture, often tinged purple, on slender petioles 1-6.5cm long; upper leaves sessile, oblong to lanceolate, dentate, gradually reduced towards inflorescence, usually persistently tomentose. Flower heads numerous on corymbosely-arranged inflorescences, each head 10-12mm high, radiate; involucres campanulate, sparingly caliculate, main bracts usually 21, linear-lanceolate, 6-8mm long, apex acute, margin scarious, tomentose toward base, usually glabrate above; bracteoles 0.5-2mm long, subulate; ray flowers 10-13 in a single whorl, yellow, ligules 7-10mm long, spreading and conspicuous, terminally 3-toothed; disc flowers numerous, perfect, slender, 5-6mm long, tube gradually expanding into very narrow, slender throat which +- equals tube, 5-toothed;

anthers obtuse to slightly sagittate at base; filaments of stamens inserted at or very near base of corolla tube; style branches not thickened above, rounded-obtuse to truncate, narrowly appendaged; stigmatic lines approaching or reaching summit of style branches. Achenes 2-2.5mm long, brownish, strongly 5-nerved and usually with a smaller rib in each interval between main ones, latter sparsely and minutely hirtellous with rather stiff, short hairs; pappus bristles numerous, silky, 6-10mm long. Fl. Apr.-Aug.

Mountain slopes and canyons; from Santa Catalina Mts [Pima County, Arizona] to New Mexico, Colorado, Canada (Correll & Johnston 1970; Shreve & Wiggins 1964).

SHEPHERDIA

(Elaeagnaceae)

Shepherdia argentea *Nuttall* **(Lepargyraea argentea** *(Nutt.) Greene***)** – bull berry, silver buffalo berry, thorny buffalo berry

Shepherdia canadensis *Nuttall* **(Lepargyraea canadensis** *(Nutt.) Greene***)** – Canadian buffalo berry, Russett buffalo berry

Native North American and Inuit peoples make the fruits of these plants into jams, or dry them in cakes for winter provisions (Usher 1974). Due to their content of β-carboline alkaloids, these plants might prove useful as MAOIs, though some of the other alkaloids present may have unknown toxic properties.

S. argentea root bark has yielded 0.2% crude bases, consisting of *tetrahydroharmol*, N-O-diacetyl-*tetrahydroharmol*, N-acetyl-pyrrolidine and N-acetyl-p-anisidine (Ayer & Browne 1970); leaves have yielded 4% quebrachitol (Plouvier 1951); seeds tested positive for alkaloids (Fong et al. 1972). The plant inhibits human plasma AChE (Orgell 1963b).

S. canadensis root bark has yielded 0.3-0.46% crude bases, consisting of *tetrahydroharmol*, N-O-diacetyl-*tetrahydroharmol*, *serotonin*, 6-OH-*tryptamine*, plectocomine [6-OH-THβC], shepherdine [6-OH-*tetrahydroharman*] and N-O-diacetyl-shepherdine (Ayer & Browne 1970); methyl apo-6'-lycopenate has also been found in the plant (Buckingham et al. ed. 1994).

Shepherdia canadensis is an unarmed shrub 1-3m tall. Leaves opposite, ovate-lanceolate to ovate, varying to narrowly-lanceolate or elliptic, 3-5cm long, obtuse, base obtuse to rounded or subcordate, green and nearly glabrous above, densely lepidote beneath. Flowers dioecious, in small clusters on twigs of the previous season, the pistillate ones usually few; hypanthium in staminate flowers saucer-shaped to cup-shaped, in pistillate flowers prolonged into a tube and persistently enclosing the ovary; staminate flowers 4-6mm wide; disc 8-lobed, at summit of hypanthium; sepals 4, ovate, greenish-yellow within, spreading, much exceeding the stamens; pistillate flowers similar, the mouth of the hypanthium closed by a dense tomentum; stamens 8, alternating with lobes of disc, inserted at or just below summit of hypanthium. Ovary 1-celled with 1 erect basal ovule. Fruit drupe-like, yellowish-red, 5-7mm long. Fl. Apr.-May.

In dry, sandy or stony calcareous soil; Newfoundland to Alaska, south to New York, n. Indiana, S. Dakota, and west to New Mexico and Arizona (Gleason 1952).

SIDA

(Malvaceae)

Sida acuta *Burm.* **(S. carpinifolia** *L.***; S. herbaceae** *Cav.***; S. lanceolata** *Willd. et Retz.***)** – spinyhead sida, broomweed, cheeseweed, huang hua ren, bala, pranijivika, bariaca kareta, dukong anak, kesar-belila, gas-bevila, mai-kward, taaiman, chichibe, malva de platanillo

Sida cordifolia *L.* **(S. althaefolia** *Swartz.***; S. rotundifolia** *Cav.***)** – Indian country mallow, malva branca, bala, batyalaka, kungyi, khareti, simak, chikana, wal-bevila, sudu-bevila, suluboo-bevila, huang hua zi [also a name for S. mysorensis]

Sida humilis *Willd.* – junka, bhumibala, palam-pasi

Sida rhombifolia *L.* **(S. canariensis** *Willd.***; S. compressa** *Wall.***; S. retusa** *L.***; S. rohlenae** *Domin.***)** – paddy's lucerne, shrub sida, common sida, arrowleaf sida, broomstick, jellyleaf, Queensland hemp, Canary Island tea, yellow barleria, huang hua mu, sidratusa, escobilla, buinar, huinar, bala, atibala, mahabala, svetberela, kheriti, kotikan-bevila, romamkap

Sida spinosa *L.* – nagabala, khar-yashtika, gulsakari, kattu-ventiyam, shamlethe-dashti

Sida urens *L.* **(S. boivinii** *Hochr.***; S. congensis** *D. Dietr.***; S. debilis** *Don.***; S. margaritensis** *Hassl.***; S. pseudo-urens** *Baker***; S. rufescens** *A. St.-Hil.***; S. sessiflora** *G. Don.***; S. verticillata** *Cav.***)**

Shamans of Veracruz, Mexico, know of the psychoactive properties of S. acuta ['male'] and S. rhombifolia ['female'], which have been reported to be smoked there as a **Cannabis** substitute. These herbs are also used locally as antiinflammatories (Diaz 1979). S. rhombifolia is also used in Mexico as a sedative, and to treat 'stomach disease' (Jiu 1966). The Cuna of Panama use S. acuta as a 'mystical medicine', and the Miskito of Nicaragua use a root extract to promote labour in pregnancy. The Marama of Bangladesh consume a masticated wad of the plant as a tranquillising remedy for 'uneasiness' (Ott 1993). S. acuta, S. humilis, S. rhombifolia and S. spinosa are used in Ayurvedic medicine as tonics and asthma treatments (Prakash et al. 1981). S. acuta is considered tonic, aphrodisiac, rejuvenative, stimulant, nervine, analgesic, vulnerary, demulcent and diuretic, having more of a tonic action on the heart than some of the other species. The whole plant is used, but usually the root ['balas'] is the item of medicine – 0.25-1g of powdered root is a medicinal dose (Frawley & Lad 1988; Ghosh & Dutt 1930). Roots of many Sida spp., not only of S. acuta, are known in India as 'balas'.

In w. Africa, the Yoruba use S. urens leaf as a virility medicine, and to relieve suffocation (Verger 1995). Hakims of India have used the seeds and perhaps other parts of S. cordifolia as an aphrodisiac, and the root has been used in Indian medicine in preparations for "increasing sexual power"; leaf and root of S. rhombifolia are also used as an aphrodisiac (Nadkarni 1976). At Mt. Hagen, Papua New Guinea, locals believe that if one eats the seeds of S. rhombifolia they "will grow smaller and smaller and finally die" (Stopp 1963)! S. rhombifolia is reputedly very effective in treating diarrhoea, for which the young tips are chewed. One person has reported that if you chew more than a couple of shoots "you'll never go again" (Cribb & Cribb 1981)! In Australia [Qld and NSW], some indigenous people use S. rhombifolia to treat diarrhoea and indigestion, either chewed or decocted. Early settlers in Queensland tried to make cord from the tough stems, hence the common name 'Queensland hemp' (Low 1990). More recently, extracts of S. rhombifolia [as S. retusa] and S. acuta have been used as ingredients in some so-called 'herbal ecstasy' products (pers. comms.).

These species have been found to contain *phenethylamines*, quinazolines and carboxylated *tryptamines*. In species studied [with some exceptions], the *phenethylamines* are the major alkaloids in the aerial parts, and the quinazolines are the major root alkaloids. Roots from 2-year old plants contained quantities of *tryptamines* equivalent to, or greater than quinazoline concentrations. Roots from 6-month old plants contain quinazolines as the major constituents. Total alkaloid yields decrease with plant age.

S. acuta roots have yielded >0.066% alkaloids – including 0.0007% *phenethylamine*, 0.0002% *ephedrine*, 0.0002% pseudoephedrine, 0.0004% vasicinol, 0.0011% vasicinone, 0.0011% vasicine [see **Peganum**], 0.08-0.35% cryptolepine [hypotensive, antimicrobial; when present, it is the sole alkaloid], 0.0015% *choline*, 0.00048% betaine and 0.00036% hypaphorine [N,N,N-trimethyltryptophan – see **Erythrina**]. Aerial parts yielded 0.0034% *phenethylamine*, 0.0015% *ephedrine*, 0.001% pseudoephedrine, 0.00008% vasicinol, 0.00036% vasicinone, 0.00044% vasicine, 0.05-0.45% cryptolepine [see above], 0.00084% hypaphorine, 0.0013% N,N-dimethyltryptophan methyl ester, 0.00124% *choline* and 0.00088% betaine. Seeds have yielded 0.26% alkaloids; the whole plant has also yielded 0.11-0.66% in plants from Negombo, India (Dutta 1964; Gunatilaka et al. 1980; Prakash et al. 1981). Ecdysterone has also been found (Rastogi & Mehrotra ed. 1990-1993).

S. chinensis root has yielded c.0.053% alkaloids, as well as steroid compounds and fatty oils (Dutta 1964).

S. cordifolia [whole plant] has yielded an average of 0.085% alkaloids; highest yields were from flowering plants. Seeds contain nearly 4 times the alkaloid levels found in other parts. Roots yielded 0.0012% *phenethylamine*, c.0.0009% *ephedrine*, c.0.0007% pseudoephedrine, 0.0016% abrine methyl ester [N-methyltryptophan methyl ester], 0.0004% hypaphorine, 0.0036% vasicinone, 0.001-0.62% vasicine, 0.0009% vasicinol, 0.002% *choline* and 0.0024% betaine; aerial parts have yielded 0.01-0.6% vasicine. The plant also contains fatty oil, phytosterols, resins and resinic acids, mucins and potassium nitrate (Ghosal et al. 1975; Ghosh & Dutt 1930; Gunatilaka et al. 1980). *Ephedrine* has not been found in Australian specimens (Cribb & Cribb 1981). In rodents, an aqueous extract of the leaves [collected before flowering] was of low toxicity, and showed analgesic and antiinflammatory activity (Franzotti et al. 2000).

S. glutinosa root has yielded 0.064% alkaloids, as well as steroid compounds and fatty oils (Dutta 1964).

S. humilis roots yielded 0.0009% *ephedrine*, 0.0007% pseudoephedrine, 0.00042% N-methylpseudoephedrine, 0.00024% N-methylephedrine, 0.00336% *phenethylamine*, 0.00016% vasicinol, 0.00048% vasicinone, 0.00036% vasicine, 0.0018% *choline* and 0.0023% betaine. Aerial parts yielded 0.01% *phenethylamine*, 0.003% *ephedrine*, 0.0026% pseudoephedrine, 0.0013% N-methylpseudoephedrine, 0.00056% N-methylephedrine, 0.00016% vasicinol, 0.00066% vasicinone, 0.0004% vasicine, 0.0029% *choline* and 0.0017% betaine.

S. rhombifolia roots yielded 0.0007% *phenethylamine*, 0.00034% N-methylphenethylamine, 0.0006% *ephedrine*, 0.00034% pseudoephedrine, 0.00076% abrine methyl ester, 0.0006% vasicinol, 0.00148% vasicinone, 0.00096% vasicine, 0.00046% hypaphorine, 0.00036% hypaphorine methyl ester, 0.00124% *choline* and betaine. Aerial parts yielded 0.0094% *phenethylamine*, 0.0038% N-methylphenethylamine, 0.0027% *ephedrine*,

0.001% pseudoephedrine, 0.00024% vasicinol, 0.00072% vasicinone, 0.00064% vasicine, 0.11% cryptolepine, 0.0017% *choline* and 0.0019% betaine (Gunatilaka et al. 1980; Prakash et al. 1981). *Ephedrine* has not been found in Australian specimens (Cribb & Cribb 1981). Leaf, stem and seed from Queensland, Australia [harv. Apr.] tested negative for alkaloids (Webb 1949).

S. spinosa roots yielded 0.00062% *phenethylamine*, 0.00056% *ephedrine*, 0.00044% pseudoephedrine, 0.00036% vasicinol, 0.00092% vasicinone, 0.00064% vasicine, 0.00066% hypaphorine, 0.00074% hypaphorine methyl ester, 0.00156% *choline* and 0.0015% betaine. Aerial parts yielded 0.003% *phenethylamine*, 0.002% *ephedrine*, 0.0016% pseudoephedrine, 0.00012% vasicinol, 0.00036% vasicinone, 0.00024% vasicine, 0.00096% hypaphorine, 0.00056% hypaphorine methyl ester, 0.0019% *choline* and 0.00166% betaine (Gunatilaka et al. 1980; Prakash et al. 1981).

S. veronicaefolia root has yielded c.0.053% alkaloids, as well as steroid compounds and fatty acids (Dutta 1964).

These alkaloid-containing species have sometimes been found to be alkaloid free, or to contain only a single major alkaloid (Gunatilaka et al. 1980; Watt & Breyer-Brandwijk 1962).

Sida rhombifolia is an erect, much-branched perennial subshrub to 1m tall; stems dull whitish-green, twiggy, fibrous with a tough stringy bark, densely hairy. Leaves alternate, shortly stalked, with narrow stipules 5-10mm long at base, blade oblong to narrow-lanceolate, 2-5 x 0.3-0.8cm, irregularly toothed, dull-green above, ashy-green below, hairy both sides. Flowers axillary, solitary on slender peduncles 1-3cm long, peduncles usually slightly longer than leaves, bent above middle; flowers yellow, 1.5-2cm diam.; calyx ashy-green, 5-lobed, 10-ribbed with stellate hairs outside, simple hairs inside, 5 sepals valvate, connate below for up to ½ their length; corolla of 5 petals, 7-8mm long, 8-12mm across, united at base, small, yellow or white; staminal tube divided at apex into numerous filaments. Ovary of 5-12 cells; ovule 1, pendulous in each cell; styles as many as carpels; stigmas terminal; carpels 7-10 with 2 short awns. Fruit enclosed by calyx, dark brown, globular, 6mm diam., vertically ribbed, dividing into 8-10 seeds; carpels separating; seeds dark brown, roundly wedge-shaped, c.2mm long, smooth, vertically 2-ribbed, bearing 2 erect, finely backward-barbed awns.

Endemic throughout tropics, commonly on moist disturbed sites in paddocks, waste places and roadsides; common along e. & n. coast of Australia, sporadically inland (Kirtikar & Basu 1980; Parsons & Cuthbertson 1992).

SILER

(Umbelliferae/Apiaceae)

Siler divaricatum *(Turcsz.) Benth. et Hook. f.* **(Ledebouriella divaricata** *(Turcsz.) Hiroë***; L. seseloides** *(Hoffm.) Wolff.***; Saposhnikovia divaricata** *(Turcsz.) Schischk.***; Stenocoelium divaricatum** *Turcsz.***; Trinicia dahurica** *Turcz. ex Bess.***)** – fang-feng ['guard against wind'], bofu, bangp'ung, saposhnikova

This herb has been used in TCM since ancient times, all parts of the plant having medicinal properties, though the leaves have been eaten as food. The spicy root is the part usually used for medicine. It has warm, pungent and sweet properties, with an affinity for the liver, spleen and bladder. Decocted in doses of 4-15g, taken in two doses, the root is used to treat headache, blurry vision, common cold, rheumatoid arthritis and bloodshot eyes. It is antipyretic, analgesic, antibacterial, expectorant, antitussive and tonic to the respiratory tract. The root is often taken together with the root of **Angelica** dahurica, 'bai zhi', and is said to be incompatible with ginger [Zingiber spp.] and aconite [Aconitum spp.] [see *Endnotes*] (Huang 1993; Keys 1976; Read ed. 1946; Reid 1995). It may also be used to treat aconite poisoning (Li 1978).

It has been written that a 'fang-feng' root that bifurcates at the top "produces madness", and one that bifurcates at the bottom "causes reversion of old ailments", though the root is generally considered non-toxic. It is uncertain as to whether this reference had any basis in fact, or indeed, if it even referred to S. divaricatum, which is known as fang-feng today (Li 1978). **Peucedanum** ledebourielloides and P. wawrii may have been used as fang-feng in the past (Wang & Lou 1989). The roots of several other herbs are also used today as varieties of fang-feng – Carum carvi ['xibei fang-feng', 'caraway'], Ligusticum brachylobum ['chuan fang-feng'], and Seseli mairei ['yun fang-feng'] (Baba et al. 1990). Glehnia littoralis ['bei sha shen' ('northern sand root')] (Bensky & Gamble 1993) is sometimes used as a substitute, known as 'shi fang-feng' in China (Wang & Lou 1989), and in Japan, the root ['hama-bofu'] is used for the same purposes as that of S. divaricatum ['bofu'] and is sometimes confused with it. The two also share similar chemistry (Okuyama et al. 2001).

S. divaricatum root has yielded chromones [0.0007% divaricatol, 0.0002% hamaudol, 0.044% sec-O-glucosylhamaudol, 0.0006% ledebouriellol], coumarins [0.001% *scopoletin*, 0.0005% fraxidin, 0.0015% isofraxidin], furanocoumarins [0.024% cimifugin, deltoin, 0.00007% (3'S)-OH-deltoin, bergapten, imperatorin, isoimperatorin, psoralen, xanthotoxin], polyacetylenes [0.092% panaxynol, 0.044% falcarindiol, 0.0078% falcarinone], 1-acylglycerols [0.0012% glycerol monooleate, 0.0004% glycerol monolinoleate] (Baba et al. 1990; Okuyama et al. 2001; Wang et al. 2000), acidic polysaccharides [saposhnikovans] (Shimizu et al. 1989a, 1989b), and 0.3-0.6% essential oil (Huang 1993). Extracts of the roots have shown CNS-inhibitory, sleep-prolonging, analgesic, anticonvulsant and antiinflammatory effects, as well as inhibiting peptic ulcers and nitrite production. The analgesic properties, at least, were attributed to a synergy of the root constituents, rather than any one group of compounds, though the chromones were the most effective (Okuyama et al. 2001; Wang et al. 1999, 2000).

Siler divaricatum is a perennial herb, with a root 1.5-2cm thick, vertical, its neck densely covered with brown leaf remnants; stem usually single, 30-80cm tall, branching from base with obliquely ascending branches nearly as long as or longer than main stem, ribbed, flexuose, stem and leaves glabrous. Radical leaves numerous, their short flattened petioles abruptly dilated into sheaths, blade oblong, 6-20 x 2-4cm, 2- or nearly 3-pinnatipartite; primary lobes oblong or ovate, petioluled, lower secondary lobes also petioluled, pinnatisect into acute narrow ovate sessile lobules; cauline leaves similar to radical but smaller, upper leaves sessile on expanded sheath, with undeveloped blade or blade obsolete. Umbels 4-6cm across, numerous, forming corymbiform panicle of 6-7 glabrous, angular, unequal rays; involucre absent; umbellets 4-10-flowered; calyx teeth short triangular, conspicuous; petals white, glabrous, broadly oval, obtuse, not notched. Ribs of ovary densely covered with transverse white excrescences becoming obliterated in fruit; stylopodium conical; styles straight at first, becoming recurved, nearly as long as stylopodium. Ripe fruit glabrous, ovoid, 5-6 x 3-3.5mm, slightly compressed dorsally, mericarps with acute prominent dorsal ribs, each with 1 large canal, valleculae broad, with 1 canal, 2 canals towards commissure. Fl. Jun.-Jul.

Pebbly steppe slopes, shrubby thickets, birch forests; e. Siberia [Dauria, Zeya-Bureya, Ussuri], Mongolia, Manchuria, China, Korea (Shishkin ed. 1986b).

SMENOSPONGIA and POLYFIBROSPONGIA

(Thorectidae)

Smenospongia aurea *(Hyatt) Wieden.* **(Aplysina aurea** *Hyatt***; A. fenestrata** *(Duchassaing et Michelotti) Carter***; Spongia fenestrata** *Duchassaing et Michelotti, non. Lamarck***; Stelospongos cribriformis var. typica** *Hyatt***)**

Smenospongia echina *(Laubenfels) Wieden.* **(S. cerebriformis** *Duchassaing et Michelotti***; Polyfibrospongia echina** *Laubenfels***; Spongia cerebriformis** *Duchassaing et Michelotti***)**

Polyfibrospongia maynardii *Hyatt*

These Caribbean sea sponges are known to have antimicrobial properties – S. aurea and S. echina extracts inhibited the growth of Staphylococcus aureus and Candida albicans (Djura et al. 1980). They are more interesting due to their occasional content of the pharmacologically-unexplored indole alkaloids 5-bromo-*DMT* [thought to probably be psychoactive when taken in a similar fashion to *DMT*] and 5,6-dibromo-*DMT* [thought to probably be inactive as a psychedelic, but has not been tested] (Trout ed. 1997e). In animals, the former alkaloid has shown sedative activity, and the latter has shown anxiolytic and antidepressant activity. The sponge indole alkaloid 6-bromo-aplysinopsin is known to bind to human 5-HT2 receptor subtypes (Kochanowska et al. 2008). There is the possibility that these alkaloids may be of dietary origin, as is thought to be the case with Verongula gigantea [see *Endnotes*] (Ciminiello et al. 2000).

S. aurea yielded 0.88% 5-bromo-*DMT* [which yielded *DMT* on hydrogenation] and 0.036% aureol [a sesquiterpene hydroquinone ether] from one sample; another sample yielded 2.2% 8-epichromazonarol and traces of a new, un-named brominated indole alkaloid (Djura et al. 1980). Yet another sample yielded 5-bromo-*DMT*, 5,6-dibromo-*DMT*, aureol, 6-bromoaplysinopsin and 6-bromo-4'-N-demethylaplysinopsin (Tymiak et al. 1985). Specimens from Florida Keys yielded 0.2% 5,6-dibromo-*DMT*, 0.36% aureol, 0.0054% 6-bromo-aplysinopsin, 0.0068% 2'-des-N-methyl-aplysinopsin, 0.0045% makaluvamine O, 0.015% uracil and 0.009% thymine (Kochanowska et al. 2008).

S. echina has yielded 0.88-0.95% 5,6-dibromo-*DMT* and 0.04% of a new phenol (Djura et al. 1980), as well as amino acids – *taurine*, *glycine*, alanine, threonine, serine, *glutamine*, *glutamic acid*, arginine, *aspartic acid*, lysine, histidine, valine, leucine, isoleucine and pipecolic acid (Bergquist 1978). As S. cerebriformis, specimens from Key Largo, Florida yielded 0.9615% ilimaquinone; 5,6-dibromo-*DMT* was detected but not isolated (Kochanowska et al. 2008).

P. maynardii yielded 5,6-dibromo-*tryptamine* and 5,6-dibromo-*N-methyltryptamine*; it has shown antibacterial properties (Van Lear et al. 1973). It has been suggested, based on chemistry combined with mor-

phology, that P. maynardii be reclassified as a Smenospongia sp. (Djura et al. 1980), though as far as I am aware this reclassification has not yet formally taken place.

Smenospongia aurea is a sea sponge, semi-incrusting to massive, amorphous, tending to lobate; consistently stiffly spongy, rubbery, very slimy after death, rigid and brittle when dry; interior often coarsely cavernous or hollow; large cavities communicate with the surface through invaginations; body c.2-25cm wide, 2-5cm high, light brown, often with reddish and purplish tinges, especially towards base; incrusting base light yellow to off-white; surface olive to yellow-green in some specimens; turns black after exposure to air. Ostia contractile, 25-200µ wide, crowded in the superficial depressions; oscules large and conspicuous, 5-10mm diam., usually on top of mounds which occasionally become conical protruberances, and have a membranaceous diaphragm; ectosome is a fleshy skin, not detachable; choanosome bright lemon yellow, fleshy, coarsely cavernous, with cavities and canals 0.5-2cm wide. Skeleton with wide, trellised primary systems; crowded primary fibres 40-180µ diam., regularly stratified, dark amber to dark brown (axial region darker, devoid of pith), connected by very short secondaries – primaries frequently branching at very low angles, often band-shaped and corrugated longitudinally; secondaries arranged in continuous planes, outlining triangular to hexagonal prisms, giving dried specimens a characteristic honeycombed surface, frequently branching near junction with primaries, occasionally anastomosing.

Coral reefs, w. Bahamas (Wiedenmayer 1977).

SOLANDRA

(Solanaceae)

Solandra brevicalyx *Standley*
Solandra grandiflora *Sw.* **(Datura sarmentosa** *Lam.***; Swartsia [Swartzia] grandiflora** *(Sw.) J.F. Gmel.***)**
Solandra guerrerensis *Martinez*
Solandra guttata *D. Don.* **(Swartsia guttata** *(D. Don.) Standl.***)**
Solandra hartwegii *N.E. Br. ex C.F. Ball* **(S. maxima** *(Sessé et Moc.) P.S. Green***; S. selerae** *Dammer ex Loes.***; Datura maxima** *Sessé et Moc.***)**
Solandra hirsuta *Dunal*
Solandra macrantha *Dunal* **(S. grandiflora var. macrantha** *(Dunal) generic VOSS***)**
Solandra nitida *Zucc.* **(Swartsia nitida** *(Zucc.) Standl.***)** – perilla, t'ima wits
Solandra spp. – chalice vine, kiéri, kiéli, tecomaxochitl, hueipatl

These plants, both revered and feared in parts of Mexico, are associated with the Huichol god of wind and sorcery, Kiéri Tewiari. According to Huichol mythology, when this god was killed, he was not permitted by the Great Spirit to die and enter the afterlife, because of his evil nature. He was thus forced to spend eternity on Earth in the rocky cliffs, growing as the 'kiéri' plant. The Aztecs once drank a leaf decoction of a Solandra sp. with 'cacao' [see **Theobroma**], as an aphrodisiac. S. guerrerensis is still used as a shamanic inebriant in the Mexican state of Guerrero. In some areas, tea made from the juice of young branches of S. brevicalyx or S. guerrerensis is consumed for the same purpose. S. nitida is also known to be 'narcotic'. The Huichol often deny knowledge of these plants, and are unwilling to discuss them with strangers. To them, a malevolent god resides within the plant, who must not be upset. The most powerful plants are considered to be those growing on cliff-edges, as opposed to those growing in forests. Of these cliff-dwelling plants, the most powerful are said to be those with a slightly reddish tinge in the throat of a mostly white flower. The most potent part of Solandra spp. is considered to be the fruit. Huichols who wish to gain favour from kiéri travel to the nearest plant, bringing all kinds of offerings, which are touched to the plant and then tied to a branch or placed at the base. The plant is then sung to or fed, and candles are lit and left to be blown out by the wind. The plants are rarely consumed, due to their dangerous effects and links to sorcery, as well as an understandable cultural preference for the more positive effects of peyote [see **Lophophora**]. Admission of using these plants is in effect an admission of guilt of practising witchcraft. Sorcerers may use them to cure damage done through offensive witchcraft (Furst 1976, 1995; Jiu 1966; Knab 1977; Rätsch 1992; Schultes & Hofmann 1980, 1992).

S. grandiflora roots yielded 0.4% *hyoscyamine*, 0.004% *hyoscine*, 0.07% cuscohygrine, 0.03% valtropine, 0.004% littorine, 0.02% tigloidine, 0.03% 3α-tigloyloxytropane, 0.02% 3-α-acetoxytropane, 0.04% cuscohygrine decomposition products, tropine and pseudotropine. Aerial parts yielded 0.08% *atropine*, 0.06% nor-*atropine*, 0.002% *hyoscine*, 0.004% valtropine, 0.004% tigloidine, 0.005% 3-α-acetoxytropane, 0.002% 3-α-tigloyloxytropane, cuscohygrine, tropine and pseudotropine.

S. guttata roots yielded 0.08% nor-*atropine*, 0.02% of a mix of *atropine* and *hyoscyamine*, 0.007% *hyoscine*, 0.003% tigloidine, 0.002% valtropine, 0.005% 3-α-acetoxytropane, 0.01% 3-α-tigloyloxytropane, tropine, pseudotropine, cuscohygrine and possibly littorine. Stems yielded 0.09% nor-*atropine*, 0.012% dl-nor-*hyoscine*, 0.004% of a mix of *atropine* and *hyoscyamine*, 0.006% tigloidine, tropine, pseudotropine, and two unidentified bases [0.001% and 0.012%]; leaves were shown to contain *atropine*, nor-*atropine*, *hyoscyamine*, nor-*hyoscyamine*, *hyoscine*, tropine, pseudotropine, and valtropine or 3-α-tigloyloxytropane.

S. hartwegii roots were shown to contain *atropine*, *hyoscine*, *hyoscyamine*, tigloidine, valtropine, tropine, pseudotropine and cuscohygrine; aerial parts contained similar alkaloids, but without cuscohygrine or tigloidine, and with nor-*atropine*, nor-*hyoscyamine* and 3α-tigloyloxytropane.

S. hirsuta roots yielded 0.16% *atropine*, 0.04% of a mix of nor-*atropine* and nor-*hyoscyamine*, 0.06% tigloidine, 0.04% cuscohygrine, 0.003% *hyoscine*, 0.02% valtropine, 0.013% 3-α-acetoxytropane, 0.016% 3-α-tigloyloxytropane, tropine, pseudotropine and littorine. Aerial parts yielded 0.15% *atropine*, 0.08% nor-*atropine*, 0.01% *hyoscine*, 0.004% tigloidine, 0.004% valtropine, 0.003% 3-α-acetoxytropane, 0.004% 3-α-tigloyloxytropane, pseudotropine, tropine and cuscohygrine.

S. macrantha roots were shown to contain mainly a mix of nor-*hyoscyamine* and nor-*atropine*, as well as *atropine*, *hyoscyamine*, *hyoscine*, tigloidine, 3α-tigloyloxytropane, 3α-acetoxytropane, valtropine, pseudotropine, tropine and cuscohygrine; aerial parts had a similar profile, but without 3α-acetoxytropane or cuscohygrine (Evans et al. 1972b).

Solandra guttata is a woody, climbing or sprawling shrub, sometimes growing epiphytically, glabrous or pubescent. Leaves alternate, entire, subcoriaceous or somewhat succulent, pubescent with simple or tree-like hairs. Inflorescences in the apices of secondary branches, with 1-several flowers; pedicels stout, generally short; calyx tubular-campanulate, pubescent, 2-5-lobed, lobes irregular; corolla gradually enlarged above, large and showy, white to yellowish, often with purplish striations, campanulate-infundibuliform, the lobules overlapping in bud, bud inflated; stamens 5, equal, the inserted ones in the upper part of the narrow portion of the tube, others exserted; filaments long, straight or curved; anthers oblongate, longitudinally dehiscent. Ovary partially inferior, 4-locular; ovules numerous; embryo curved.

Veracruz, Mexico (Nee 1986).

SOLANUM

(Solanaceae)

Solanum dimidiatum *Raf.* **(S. perplexum** *Small***; S. torreyi** *A. Gray***)** – western horsenettle, potato weed, Torrey's nightshade
Solanum dulcamara *L.* – bittersweet, woody nightshade, kakmachi, bhalu-mash
Solanum ellipticum *R. Br.* **(S. lithophilum** *F. Muell.***)** – wild tomato, native tomato, wild gooseberry, potato bush, kulypurpa, tawal-tawalpa, yuralpa, wangki
Solanum esculentum *Dunal* **(S. melongena var. esculentum** *(Dunal) Nees***)**
Solanum hirtum *Vahl* – papaya des jaguars
Solanum hypomalacophyllum *Bitter ex Pittier* – borrachera ['intoxicant']
Solanum inaequilaterale *Merr.*
Solanum kwebense *N.E. Br. ex C.H. Wright*
Solanum melongena *L.* – eggplant, aubergine, berenjena, vartaku, baigun
Solanum nigrum *L.* – black nightshade, blackberry nightshade, glossy nightshade, poisonberry, physalis, strychnos kêpaion
Solanum renschii *Vatke* – laibalayok
Solanum spirale *Roxb.* – bagua, mungas kajur
Solanum tuberosum *L.* – potato, batata, pomme de terre, kartappe, golalu, alu
Solanum villosum *Mill.* **(S. alatum** *Moench***; S. luteum** *Mill.***; S. miniatum** *Bernh. ex Willd.***; S. nigrum var. villosum** *(L.) Mill.***; S. rubrum** *Mill.***)** – tomate de la bruja ['tomato of the sorcerer'], tomatillo del diablo, hierba mora
Solanum spp. – nightshades

Nightshades are herbaceous plants, including the common eggplant [S. melongena] and potato [S. tuberosum], both of which have toxic as well as edible parts (Chevallier 1996). Nightshades were reported as a common ingredient in witch's flying ointments [see *Methods of Ingestion*] (Rätsch 1992), but it is doubtful that this refers to Solanum spp. Many Solanaceae are referred to as nightshades, and often erroneous identifications are made by laypeople. For example, in Britain, S. dulcamara is often pointed out to children as 'deadly nightshade' [see **Atropa**] (theobromus pers. comm.), and in Australia, the same applies to S. nigrum (pers. obs.).

Many people believe the berries of S. nigrum to be poisonous, but this only applies to green, unripe berries; black, ripe berries are good for making an edible jam. However, this does not apply to berries of all Solanum spp. In many parts of the world, the cooked leaves are eaten as a vegetable – when fresh, they act as an analgesic and tranquilliser. The plant has poisoned animals, sometimes causing death. In humans, the plant is claimed to cause stupefaction, staggering, mydriasis, difficulty in speaking, anaesthesia, cramps and sometimes convulsions. These symptoms may be due

to confusion with those of 'deadly nightshade', **Atropa** belladonna. A water infusion or decoction of S. nigrum may cause transient stimulation, followed by CNS-depression; low doses increase cardiac output, and large doses depress it. Plasma cholinesterase is also inhibited (Bremness 1994; Low 1991b; Roddick 1986; Watt & Breyer-Brandwijk 1962). An extract of the herb was once regarded as having narcotic properties of "the same power as lettuce-opium" [see **Lactuca**] (Bailey 1880).

In Africa, S. nigrum has been used to divine the whereabouts of lost objects or criminals (Rätsch 1992). 'Rain doctors' of the Southern Sotho and Tswana use the ripe berries in magical preparations to bring rain; this use is apparently due to the black colour of the fruits, in symbolic relation to dark rain-clouds (Mehra 1979). In Italy, S. nigrum has been used as a sedative, diaphoretic, antispasmodic and emollient (Watt & Breyer-Brandwijk 1962). In India, it is known as an aphrodisiac and laxative tonic, and the unripe fruits have caused deliriant and fatal poisoning in children. Also in India, S. dulcamara berries, decocted in a dose of c.60g, are known to be mildly narcotic, sedative, cardiotonic, diaphoretic and diuretic. Shepherds used to hang the plant around the necks of sheep thought to be under the influence of the 'evil eye', as a charm. Leaves of S. esculentum are also narcotic, and are given to relieve intoxication. The root of S. spirale also has narcotic properties (Grieve 1931; Kirtikar & Basu 1980; Nadkarni 1976).

In Spain, S. villosum is known as 'tomate de la bruja', hinting at use by sorcerers (Rätsch 1998). The Lacandon Maya of Chiapas, Mexico, refer to S. hirtum [which is similar in appearance to the eggplant, S. melongena] as 'papaya of the jaguar', indicating knowledge of possible psychotropic effects, the jaguar being a shamanic animal. Chewing the de-spined leaves produces a numbing effect, with larger amounts causing a 'strange inebriation' (Rätsch pers. comm.). In Mexico the flowers of S. melongena are used as a hypnotic and hypotensive (Heffern 1974); in India, the leaves are considered narcotic, the seeds stimulant and cardiotonic, and the fruit hypnotic (Nadkarni 1976; Vohora et al. 1984). S. hypomalacophyllum from Venezuela may also be intoxicating, as its common name suggests. S. topiro seeds are sometimes dried, powdered, and added to coca powder [see **Erythroxylum**], when the tongue and mucous membranes have been irritated by over-use. The leaves are applied externally to treat headache (Schultes & Raffauf 1990). In n.e. Peru S. oblongifolium var. soukupii ['tululuche'] leaf is infused to treat colds and bronchitis, yet a concentrated decoction is used to poison animals (De Feo 2003). In the Peruvian Amazon, S. kioniotrichum ['siuca-huito'] is sometimes used by sorcerers to inflict harm upon others (Luna & Amaringo 1991).

In e. Africa, the Samburu consume S. renschii for strength; a fruit extract was shown to "diminish the power of conductivity of nerves, and temporarily stimulate cardiac action" (Lehmann & Mihalyi 1982). In w. Africa, S. verbascifolium is used as an ordeal poison (De Smet 1998). The South African S. kwebense is known to cause an intoxication in cattle known as 'crazy cow syndrome', as does the Texan S. dimidiatum (Griffin & Lin 2000). In Queensland [Australia], berries of S. armatum have caused narcotic poisoning in horses (Webb 1948). The leaves of S. ellipticum are sometimes used by the Pitjantjatara as a 'pituri' substitute [see **Duboisia**, **Nicotiana**] (Latz 1995); some aboriginal groups have been reported to chew the leaves as a tobacco substitute (Low 1990), which may refer to the same useage. In the Philippines, S. inaequilaterale leaves are smoked as a tobacco substitute (Lewis & Elvin-Lewis 1977). In Tari, Papua New Guinea, S. torvoideum is used in rituals for fighting and battle [see **Galbulimima**] (Paijmans ed. 1976).

S. tuberosum has caused poisonings in humans, after ingestion of green potatoes [the alkaloids mentioned below are concentrated in the green parts]. Symptoms included hallucinations, confusion/delirium, abdominal pain, vomiting, diarrhoea, anorexia, cyanosis and coma; deaths have occurred on occasion (Roddick 1986). Children who ate the berries of S. sodomaeum in Australia suffered "congestion of the blood vessels, sweating, dimness of sight, dizziness, vomiting and purging", followed by death (Webb 1948).

Many Solanum spp. contain steroidal glyco-alkaloids such as solanine, concentrated in the unripe berry, and also found in aerial parts. Solanine is quite toxic, and is an AChE-inhibitor (Patil et al. 1972).

S. melongena has yielded 0.00005-0.0003% *tryptamine*, 0.0002% *serotonin*, and 0.0003% *tyramine* from its fruit (Udenfriend et al. 1959). The plant also contains calystegines (Griffin & Lin 2000) and the coumarins *scopoletin* and aesculetin [0.0008% in leaves, 0.0004% in root, w/w] (Kala 1958); HCN was detected in the whole plant (Watt & Breyer-Brandwijk 1962). An alkaloid fraction from the leaves acted as an analgesic and slight CNS-depressant in rats and mice (Vohora et al. 1984); components of the plant also inhibit AChE (Whitaker & Feeney 1973).

S. nigrum has yielded solanine, solamargine, solasodine [4-6% in fruit], solasonine, solanigridine and vitamin C. HCN was also detected in the fruit. Frying or boiling does not destroy the alkaloids, and frying can actually concentrate them (Roddick 1986; Watt & Breyer-Brandwijk 1962). The plant inhibits human plasma AChE; S. tuberosum and S. chacoense were much more potent in this regard, and S. melongena and S. rostratum much less so (Orgell 1963b).

S. sodomaeum leaves were shown to contain calystegines B2 & B3 (Bekkouche et al. 2001).

S. torvum aerial parts contain *GABA* (Durand et al. 1962).

S. tuberosum tuber [the potato itself] has yielded *diazepam* [0.003-0.01ng/g], N-desmethyldiazepam, lorazepam, delorazepam, 2'-chlorodiazepam (Unseld et al. 1989; Wildmann et al. 1988), 0.00006% *narcotine* (Rimpler 1965), 0.0001% *tyramine*, *dopamine* and 0.00001-0.0002% *norepinephrine* (Smith 1977a; Udenfriend et al. 1959), as well as 0.01% [w/w] calystegines in the skin of the tuber (Griffin & Lin 2000). Solanine is concentrated in the green parts of potatoes that form when the tubers have been exposed to light (Patil et al. 1972). When bruised, the tubers form dopachrome [see *Neurochemistry*, and *adrenochrome* in *Chemical Index*] as an intermediate product; it may be formed less than 6 hours after initial bruising, and can be recognised by its orange colour. The dopachrome is formed from tyrosine, by the enzyme tyrosinase. The black discolouration that later develops is due to the formation of melanin from dopachrome (Boyer 1977; Friedman & Daron 1977; Muir & Ross undated). Some constituents of S. tuberosum inhibit AChE (Whitaker & Feeney 1973). Leaves have yielded 0.0002% *serotonin*, and fruits 0.00075% *serotonin* [both w/w] (Engström et al. 1992).

Calystegines [see **Convolvulus**] have also been found in S. dimidiatum, S. dulcamara and S. kwebense (Griffin & Lin 2000).

Solanum nigrum is a variable annual herb; stem erect, glabrous or +- pubescent, much divaricately branched. Leaves numerous, alternate or subopposite, 2.5-9 x 2-5cm, ovate-lanceolate, subacute or acuminate, glabrous, entire, sinuately toothed, tapering to the petiole; petioles 2cm long. Flowers small, in extra-axillary subumbellate 3-8-flowered cymes; peduncles 6-20mm long, slender; pedicels 6-10mm long, very slender; calyx 3mm long, glabrous or nearly so, 5-lobed, lobes oblong, obtuse, 1.25mm long, not enlarged in fruit; corolla 4-8mm long, divided more than ½ way down into 5 oblong subacute lobes; stamens (4-)5(-6) in corolla-throat; filaments short, flattened, hairy at base; anthers 2.5mm long, yellow, oblong, obtuse, often narrowed upwards, notched at apex. Ovary globose, glabrous, 2-celled; style cylindric, columnar, hairy; stigma small. Berry c.6mm diam., globose, purplish-black when ripe, smooth, shining; seeds discoid, 1.5mm diam., minutely pitted, yellow.

Temperate and tropical regions of the world; a widespread introduced weed (Kirtikar & Basu 1980).

A very variable species that can be confused with similar Solanum spp., such as S. americanum [which probably has similar pharmacology].

SOPHORA

(Leguminosae/Fabaceae)

Sophora flavescens *Aiton* **(S. angustifolia** *Sieb. et Zucc.***; S. macrosperma** *DC.***; S. tetragonocarpa** *Hayata***)** – ku sheng

Sophora japonica *L.* **(S. mairei** *H. Lév.***; S. pubescens** *Tausch***; S. sinensis** *Forrest***; Ormosia esquirolii** *H. Lév.***; Robinia mitis** *Lour.***; Styphnolobium japonicum** *(L.) Schott***)** – pagoda tree, Chinese scholar tree, huai hua, long zhao huai

Sophora secundiflora *(Orteg.) Lag. ex DC.* **(S. sempervirens** *Engelm.***; S. speciosa** *Benth.***; Agastianus secundiflora** *(Orteg.) Raf.***; Broussonetia secundiflora** *Orteg.***; Calia erythrosperma** *Teran et Berland.***; C. secundiflora** *(Orteg.) Yakovlev***; Cladrastis secundiflora** *Raf.***; Dermatophyllum speciosum** *Scheele***; Virgilia secundiflora** *Cav.***)** – mescal bean, Texas mountain laurel, frijolitos

Sophora spp.

Mescal bean, S. secundiflora, is cultivated for its beautiful flowers, yet the plant has a more interesting history of use. The small red 'mescal beans' have reportedly been used as a ritual intoxicant in n.e. Mexico and adjacent US, possibly for thousands of years [though little used today, if at all], as well as being made into necklaces for adornment [the predominant form of use]. They have been discovered in cave excavations dating back to 7000BC, often together with seeds of Ungnadia speciosa [Sapindaceae; 'Texas buckeye']. Texas 'Indians' have used the seeds as barter money – it has been reported that a 15cm string of the seeds could buy a pony. The name mescal bean probably originated from confusion with peyote [see **Lophophora**] and the Agave spp. liquor 'mezcal', which are used in the same general area as S. secundiflora. Apparently, the beans have sometimes been added to mezcal to make it stronger. The Wichita used the seeds in initiations, to produce vomiting and visions. The Omaha used it as a powerful medicine before hunting or battle; the seeds were consumed, or in the latter case, rubbed on the body, to produce a 'strengthening' effect. The Iowa would harvest the beans in spring, roasting them until they turned yellow, then grinding them and infusing in water with other herbs; this infusion was then strained and drunk. Some groups, such as the Kiowa, had mescal beans adorning the leader of the peyote ritual – the Kickapoo say this is because S. secundiflora 'shades and protects' peyote in the wild. The mescal bean ritual of central and southern Plains Indians was called the 'Red Bean Dance' [also 'deer dance' or 'Wichita dance'], which shares many common traits with peyote rituals. For the dance, the beans were brewed with unidentified herbs, which made the drink 'milder'. Many scholars believe that use of the mescal bean was an early form

of worship which decreased in practice when the safer properties of peyote were discovered. Today, many doubt that the beans were ever used as an intoxicant at all (Adovasio & Fry 1976; Allen & Allen 1981; De Rios 1990; Diaz 1979; Emboden 1979a; Furst 1976; Hatfield et al. 1977; Ott 1993; Schultes 1937a, 1937b, 1969c).

S. japonica, common in temple gardens, is used medicinally in China for its flowers to stop fever and bleeding, as well as to control high blood pressure, nervousness and dizziness. The leaves and pods have been used to adulterate 'opium' [see **Papaver**], and a yellow dye made from the pods was once much-valued for dyeing silk in the Orient (Allen & Allen 1981; Bremness 1994; Huang 1993). S. flavescens is used medicinally in China as 'ku sheng' ['bitter root'], and acts as an antiarrhythmic, antiasthmatic, expectorant, anthelmintic and diuretic. Side effects may include gastric pain, nausea, vomiting and constipation (Huang 1993).

S. secundiflora seeds [the 'beans'] are highly toxic – one thoroughly chewed seed has been known to kill a child [though adults and some children may tolerate more], and the plant has caused poisonings in stock animals. Whole seeds may pass through the digestive tract harmlessly. The intoxicating dose is usually ¼-3 seeds. Symptoms may include nausea, vomiting, diarrhoea, convulsions, headache, excitement, hallucinations and delirium; overdose will produce a comatose state sometimes ending in death due to respiratory failure, though often a sub-lethal dose will end in a prolonged sleep state lasting several days. The effects are due to the *nicotine*-like *cytisine* and related quinolizidine/pyrrolizidine alkaloids, which affect *acetylcholine*-receptors [see also **Cytisus**, **Laburnum**, **Lupinus**] (Allen & Allen 1981; Barlow & McLeod 1969; Blackwell 1990; De Rios 1990; Emboden 1979a; Foster & Caras 1994; Hatfield et al. 1977; Schmeller et al. 1994; Turner & Szczawinski 1991). Despite this, their use has been suggested as a potential legal 'high' (Gottlieb 1992), and have very rarely been ingested for such purposes in more recent times (Keller 1975). There is one clinical report of a young man who consumed an unknown amount of S. secundiflora seeds, before being arrested and taken to an emergency ward. Symptoms observed included "fluctuating level of consciousness with intermittent agitation", delirium, sweating, mydriasis, and high temperature, heart rate and blood pressure. He had largely recovered 3 hrs after admission [and with benzodiazepines] (Wiegand & Smollin 2007).

S. flavescens root has yielded d-matrine, d-oxymatrine, l-anagyrine, l-baptifoline, *cytisine*, N-methylcytisine, d-sophoranol, l-13-ethylsophoramine, kuraridin, norkurarinone and trifolirhizin; when consumed, many of the alkaloids apparently convert to d-matrine, which is considered the main active component of the herb (Huang 1993). The methanol extract of the root yielded oxymatrine, trifolirhizin, β-sitosterol and the flavonoids formononetin and kushenol F; the latter two compounds inhibited mouse brain MAO, affecting MAO-B slightly more than MAO-A (Hwang et al. 2005).

S. japonica stems and leaves [harv. Jan., New Zealand] were found to contain *cytisine*; no sparteine was detected. Seeds appeared to contain no alkaloids (White 1951), but do contain saponins which yield sophorins A-C, sophoradiol and betulin on hydrolysis (Huang 1993).

S. secundiflora seeds have yielded 0.15-0.25% *cytisine*, 0.026-0.04% N-methylcytisine, 0.018-0.03% sparteine [CNS depressant], 0.003% epilupinine, Δ5-dehydrolupanine, 0.001% anagyrine, thermopsine [not found in some tests], 4-OH-2-piperidinecarboxylic acid and N-γ-glutamyltyrosine; unripe pods also contain lupanine [CNS depressant], 11-allylcytisine, β-isosparteine and rhombifoline. Leaves have yielded argentine, *cytisine*, N-methylcytisine, lupinine, sparteine and thermopsamine. Leaves in one test contained no alkaloids. Seeds had an LD50 of 1.4g/kg [oral] in mice (Harborne et al. ed. 1971; Hatfield et al. 1977; Henry 1939; International… 1994; Keller 1975; Nucifora & Malone 1971).

Sophora secundiflora is an evergreen shrub, 0.5-3.5m tall, usually with dense dark-green glossy foliage. Leaves alternate, glabrous or slightly pubescent at maturity, once-imparipinnately-compound; leaflets very firm, 5-11(-13) per leaf, often 17mm or more wide, and glabrous above, +- ovate; stipules minute, deciduous. Flowers in terminal or axillary, usually densely flowered racemes 5-15cm long, 5-10cm wide, individual flowers bluish-purple and very showy, 1-2cm long, the banner external to the others in bud; calyx of 5 sepals united above the floral cup; corolla strongly bilaterally symmetrical and papilionaceous; stamens 10, the filaments free above the top of the floral cup. Fruit a 1-several-seeded indehiscent or very tardily dehiscent woody pod, 2-12cm long, 11mm or more thick, equally as wide, moderately constricted between seeds; seeds red.

Frequent in bushy vegetation; Texas, New Mexico, n. Mexico (Correll & Johnston 1970).

Grow outdoors in hot climates, indoors in cold; prefers hot sun and a well-drained alkaline soil. Nick and soak seeds before planting; may also be propagated from cuttings. Keep soil on the dry side, except when in flower (Grubber 1973).

SPATHIPHYLLUM

(Araceae)

Spathiphyllum cannaefolium *(Dryand.) Schott* **(S. bonplandii** *Schott***; S. candicans** *Poepp.***; S. cannaeforme** *(Curtis) Engl.***)** – djê'-gaí-rê, fruit-fly plant
Spathiphyllum sp. – nampiá
Spathiphyllum spp. – peace lily, spathe flower, white anthurium

A Spathiphyllum sp. known as 'nampiá' is used by the Hupda-Maku of the north-western Amazon as an additive to their ayahuasca brews [see **Banisteriopsis**]. It is said to strengthen the brew and give very bright visions. Men of this group may also sometimes rub the leaves of the plant on their bodies, as a magical scent to 'conquer' women (Leite da Luz undated). S. cannaefolium has been reported to be used to flavour tobacco [see **Nicotiana**] by natives of Venezuela, Colombia and Guyana (Plowman 1969). It is used by the Witoto to produce an alkaline powder for coating the orally-active pills that they prepare from **Virola** theiodora. To make the powder, the root, leaves, and inflorescence are burnt, and the ash leached out with cool water, which is later evaporated to yield the alkaline powder ['hê'-rog']. S. cannaefolium is considered one of the best sources for this powder. The Tukano and Gwanano rub the inflorescence of S. floribundum on the forehead, to relieve headaches (Schultes & Raffauf 1990; Schultes & Swain 1976). Stem-sap from S. cochlearispathum is considered poisonous by the Chimantec of Mexico (Plowman 1969).

The chemistry of this genus is still relatively unknown, though the flowers of some species have been analysed for flavonoids (Schultes & Raffauf 1990). As with many Araceae, S. cv. clevelandii has been shown to contain calcium oxalate raphides [see **Tillandsia**], which can cause intense irritation when ingested (Schmidt 1984). Apparently, human poisonings from eating Spathiphyllum spp. are relatively common, as various species and cultivars are often encountered as house plants (Oregon Poison Centre 1996). Preparing a filtered decoction would eliminate the water-insoluble raphides, though many plants containing calcium oxalate raphides also contain soluble oxalic acids, which can be toxic in excess [see **Delosperma**, **Sceletium**].

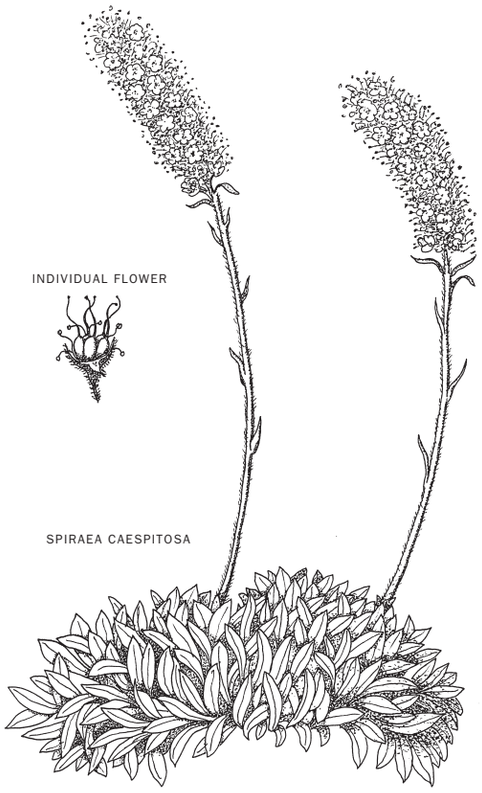
S. cannaefolium mature flower spikes have yielded an essential oil containing mostly benzyl acetate [59%], *methyleugenol* [20%], *estragole* [relative quantity not given], propyl/isopropyl tetradecanoate [6%] and p-MeO-benzyl acetate [c.3%]. Spikes lose their fragrance with age. Benzyl acetate and *methyleugenol* have been shown to be responsible for the fly-attracting powers of this plant, giving rise to one of its common names [see above] (Lewis et al. 1988).

Spathiphyllum spp. are stemless or shortly-stemmed aromatic herbs; leaf petioles equitant, long, apex usually geniculate, terete, subthickened, sheathed up to or beyond middle; leaf oblong, cuspidate-acuminate, middle nerve strong, lateral nerves subparallel, close, adscending or spreading, curved near margin. Peduncle leaves +- same length; spathe cuspidate, in peduncle +- decurrent, membranaceous, at first convolute, then at base becoming flattened out, vegetation persistent; spadix sessile or stipitate, cylindroid, erect, spathe short, densely multiflowered, flowering first below then continuing upwards; flowers hermaphroditic, perigoniate; tepals 6, apex arched, nearly truncate, coherent or in cyathium, truncate, connate; stamens 6[-8], opposite tepals; filament short, apex becoming dilated and incrassate, planar on front, humped on back, apex abruptly narrowing in connective; anther filaments long, ovoid, laterally semi-oblong, connective longer, locules subopposite, externally variable, longitudinal fissure barely extending near base, dehiscent. Ovary oblong, 3-4-locular; ovules in locule 8-6-4-2 side by side or one above the other, anatropous, micropyle situated towards base, funicle shortly erect, mid-axially affixed; style continuous with ovary, conic-elongate, moderately thick, beyond perigonii phylla long exserted or +- entirely lacking; stigma 3-4-lobed, sessile. Fruit a berry, vertex rotundate or conical-attenuate, 3-locular, locules 1-2-seeded; seeds oblong, curved, pallid yellowish, attenuate towards micropyle, funicle shortly minutely verrucose, rhaphe laterally thick and slightly raised, testa sparsely striate-verrucose, when dried provided with longitudinally-arranged pits; embryo axil slightly curved, narrowly cylindrical in copious albumen.

Tropical central and S. America (Fridericus & De Martius ed. 1965-1975), Philippines, tropical s.e. Asia (Schultes & Raffauf 1990).

SPIRAEA

(Rosaceae)



Spiraea caespitosa *Nutt.* **(Petrophytum caespitosum** *(Nutt.) Rydb.***)** – caespitose rock spiraea

This small herb is used as a narcotic by the Kayenta Navajo, but there seems to be little other information regarding the plant (Ott 1993). The analgesic drug aspirin was named in derivation from Spiraea, due to its natural precursor [salicylic acid] being found in the genus (Lewis & Elvin-Lewis 1977). In China, S. blumei is drunk as a tea (Usher 1974).

S. bracteata contains *phenethylamine* (Hartmann et al. 1972).

S. caespitosa contains salicylic acid [analgesic] (Lewis & Elvin-Lewis 1977).

S. japonica contains a variety of diterpene alkaloids called spirasines (Sun et al. 1987).

S. prunifolia gave positive tests for hydrocyanic acid [HCN] (Watt & Breyer-Brandwijk 1962).

Spiraea caespitosa is a densely caespitose woody plant with prostrate branches, forming low, depressed mats. Leaves persistent, canescent, crowded, entire, spatulate, 5-12mm long, 1-nerved, densely silky-pubescent. Flowers racemose, perfect; raceme narrow, 1-4cm long, usually simple; peduncles 3-10cm long, silky, with small bract-like subulate leaves; sepals 5, valvate, ovate-lanceolate, acute; petals 5, imbricate, white, spatulate or oblanceolate, 1.5mm long; stamens c.20; pistils 3-5. Ovary 1-celled, densely pubescent; style filiform. Fruit follicles, dehiscent along both sutures. Fl. Jun.-Sep.

On rock ledges; Montana and Black Hills, South Dakota, to California [southern Sierra Nevada, Panamint, Providence Mts], Arizona and New Mexico (Abrams 1940-1944).

STELIS

(Orchidaceae)

Stelis sp. – kemishitsa

'Kemishitsa', tentatively identified as a Stelis sp., is known to the Machiguenga of e. Peru as a powerful hallucinogen. It is used to help attain status as a 'seripegari', or shaman (Russo undated). Little else appears to be known of the chemistry or useage of this genus, though unidentified alkaloids have been detected in four unidentified Stelis spp. (Lüning 1967).

Stelis spp. are epiphytic or rock-dwelling herbs; stems caespitose or repent, occasionally producing offsets, unifoliate, not pseudobulbous. Leaves coriaceous, base often contracted in petiole. Inflorescence an elongate raceme, never uniflorous; bracts alternate, often arranged in two opposite rows, imbricate; flowers very small or minute, very often secund; sepals equal to subequal, generally spreading, shortly or deeply connate, occasionally urceolate, rarely entirely converging synsepalous, tissue thin or fleshy; petals generally fleshy, many times shorter than sepals, wide, apex +- thickened; labellum concave, fleshy; disc transverse, biparted, entire at base, 6 lamellae obliquely inserted laterally; column shortened, generally sessile, dilated upwards, very fleshy, bibrachiate; clinandrium prominent, stigmas 2, in brachiis distinct, lateral; rostellum very much extended; anthers terminal, operculate, incumbent; pollinia 2, waxy, apex often viscid, sparingly connected (Dunsterville & Garay 1979).

Cultivate in small pots with sphagnum moss or fine bark mix; can be propagated by division. Keep moist, humid and shaded; cold tolerant (Banks & Perkins 2005).

STEMMADENIA

(Apocynaceae)

Stemmadenia donnell-smithii *(Rose) Woodson* **(Tabernaemontana donnell-smithii** *Rose***; T. donnell-smithii var. costaricensis** *Donn.-Sm.***)** – cobal, cojón, cojón de puerco

Stemmadenia galeottiana *(A. Rich.) Miers* **(S. bella** *Miers***; S. bignoniiflora** *(Schltdl.) Miers***; S. galeottianum** *B.D. Jackson***; S. insignis** *Miers***; Echites bignoniiflora** *Schltdl.***; Odontostigma galeottiana** *A. Rich.***; Tabernaemontana laurifolia** *Schott non L. ex Miers***)**

Stemmadenia glabra *Benth.* **(S. calycina** *Brandegee***; S. mollis** *Benth.***; S. obovata** *(Hook. et Arn.) K. Schum.***; S. pubescens** *Benth.***; Bignonia obovata** *Hook. et Arn.***)**

Stemmadenia grandiflora *(Jacq.) Miers* **(S. pauciflora** *Woodson***; S. pennellii** *Woodson***; Malouetia riparia** *(Kunth) DC.***; Tabernaemontana grandiflora** *Jacq.***; T. riparia** *Kunth***)** – yellow laurel

Stemmadenia minima *A.H. Gentry* **(S. macrophylla** *Greenm.***)**

Stemmadenia tomentosa *Greenm.* **(S. decipiens** *Woodson***; S. palmeri** *Rose ex Greenm.***; S. sinaloana** *Woodson***)**

These obscure plants have only several recorded uses that I could find. S. donnell-smithii is used in Central America to treat rheumatism, toothache and eye inflammation (Valencia et al. 1995). S. galeottiana [of Cuba and s.e. Mexico] bleeds a latex that is used as a chewing gum in Mexico (Usher 1974).

As with many other Apocynaceae [eg. see **Tabernaemontana**, **Tabernanthe**, **Voacanga**], Stemmadenia spp. are known to contain some interesting indole alkaloids.

S. donnell-smithii wood has yielded 0.09% *voacangine*; bark yielded 0.001% *tabernanthine*, 0.003% isovoacangine, 0.0086% (+)-quebrachamine and 0.0004% *voacamine*; fruits yielded 0.015% stemmadenine.

S. galeottiana wood yielded 0.02% *ibogamine* (Walls et al. 1958).

S. glabra has yielded *ibogamine* and tabersonine (Ganzinger & Hesse 1976); leaf contains traces of bis[11-OH-coronaridin-12-yl], 11-OH-*coronaridine* and *voacristine*, as well as obovatine and a sarpagine-type alkaloid, N-methyl-11-OH-macusine A (Madinaveitia et al. 1995; Valencia et al. 1995).

S. grandiflora has yielded 14-β-OH-quebrachamine, 3-oxovincadifformine and 14,15-dehydrotetrastachynine (Buckingham et al. ed. 1994; Ganzinger & Hesse 1976).

S. minima has yielded 16-epi-panarine from the bark (Achenbach et al. 1991), heyneanine and *voacristine* from the branches, and 0.64% 13-OH-*coronaridine* from the leaves. Roots yielded 0.6% alkaloids, which was mostly *coronaridine* and *voacangine*, with decreasing amounts of *ibogamine*, heyneanine, 19-oxo-*coronaridine*, *voacristine*, *ibogamine*-OH-indolenine, *coronaridine*-OH-indolenine and *voacangine*-OH-indolenine. Stem and stem bark contain the same alkaloids in similar proportions, but at a lower yield [0.02% and 0.31%, respectively] (Gupta, M.P. et al. 1991).

S. tomentosa has yielded vinervine (Buckingham et al. ed. 1994); S. tomentosa var. palmeri has yielded tabersonine (Ganzinger & Hesse 1976).

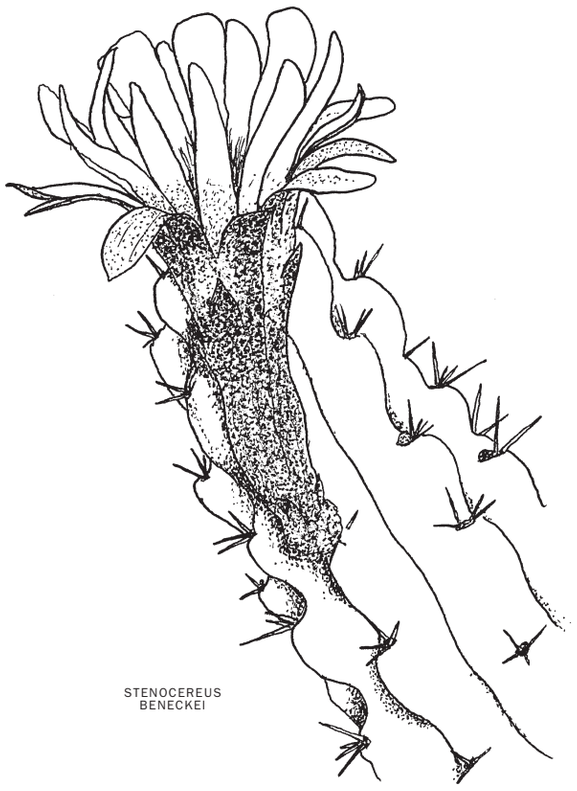
Stemmadenia donnell-smithii is a shrub or small tree, yielding a latex. Leaves entire, opposite, 6-8cm long, 3-3.5cm wide, spatulate, minutely glandular-puberulent or glabrate above, underside conspicuously barbate in axils of mid-vein; petioles 1-2mm long; sheaths of petioles meeting in shallow ring around stem, sheltering many small, fusiform glands. Inflorescence a terminal reduced raceme, 1-4-flowered; bracts placed midway on pedicels; corolla yellow, salverform, tube 2.5-3cm long, limb 1.5-2cm long, lobes 5, equal, dextrorsely reflexed and strongly auriculate, with 5 linear interior appendiculate folds, opposite and slightly above stamen-attachment; calyx yellowish, nearly equalling corolla-tube in length, 2-2.5cm long, lobes 5, unequal, ovate, imbricate, 1.5-2cm broad, in 2 closely imbricated series (usually 3 larger interior and 2 smaller exterior lobes), bearing several cycles of small fusiform glands within, and near disc-attachment; stamens 5, included, attached to corolla at summit of tube, alternate with corolla lobes; filaments short, thick, unguiculate at anther-attachment; anthers of 2 elongate, unappendaged sporangia near-

ly parallel to base. Carpels 2, sessile, unilocular, with many ovules on lateral binate ventral placenta; style long, filiform; stigma terminal, borne on fleshy truncate clavuncle; disc shallow, immersed, entire; nectaries fleshy, coalescing into +- irregular, nearly smooth rim, around and slightly adnate to carpels. Fruit a pair of divaricate, leathery, glandular-punctate follicles c.3.5cm long, 3cm broad, rounded at apex; seeds many, striate, albuminous, ecomose, immersed in oily arilar pulp.

Tropical forest; s. Mexico, through Central America (Woodson 1928).

STENOCEREUS

(Cactaceae)



Stenocereus beneckei *(Ehrenb.) Backeb.* **(Hertrichocereus beneckei** *Backeb.***; Lemaireocereus beneckei** *(Ehrenb.) Br. et R.***)**

Stenocereus eruca *(Brandegee) A. Gibs. et Horak* **(Lemaireocereus eruca** *Br. et R.***; Machaerocereus eruca** *(Brand.) Br. et R.***)** – creeping devil, dagger cactus

Stenocereus stellatus *(Pfeiff.) Riccob.* **(Lemaireocereus stellatus** *(Pfeiff.) Br. et R.***)** – pitayo, xoconochtle

Stenocereus treleasii *(Br. et R.) Backeb.* **(Lemaireocereus treleasii** *(Vaupel) Br. et R.***)** – tunillo

The fruits of Stenocereus spp. are known as 'pitaya' in Mexico, and have served there as an edible fruit crop since ancient times (Pimienta-Barrios & Nobel 1994). Pitaya, however, is a name generally applied to all edible fruits from columnar cacti (Trout pers. comm.). The Seri of Sonora use heated slices of despined S. thurberi ['pitahaya dulce', 'organ-pipe cactus'] stem, wrapped in a cloth, to apply to rheumatic pains (Felger & Moser 1974).

S. beneckei was shown to contain <0.01% *mescaline*, c.0.01% *DMPEA* and 0.01% 3,5-dimethoxy-4-OH-*phenethylamine* (Ma et al. 1986); the surface wax contains the triterpenes lupeone [0.12%], lupeol [0.04%] and β-amyrin, in a ratio of 3:1:1; oleanolic acid and queretaroic acid were also isolated, but may have been artefacts of the extraction process (Kinoshita et al. 1992; Wollenweber & Dörr 1995).

S. eruca was shown to contain <0.01% *mescaline*, <0.01% *DMPEA* and 0.01% or less of 3,5-dimethoxy-4-OH-*phenethylamine*.

S. stellatus was shown to contain c.0.01% of each of these alkaloids (Ma et al. 1986), as well as 0.35% triterpenes, including oleanolic acid, betulinic acid, stellatogenin and thurberogenin (Trout ed. 1999).

S. treleasii was shown to contain c.0.01% of each of the alkaloids found in S. eruca (Ma et al. 1986), as well as 0.1% oleanolic acid, 0.64% stellatogenin, 0.02% thurberogenin and treleasegenic acid (Trout ed. 1999).

Stenocereus stellatus is an erect, columnar cactus up to 4m tall, branching from the base; branches ascending, 6-7(-9)cm thick, light green when young, later matt dark green, often reddish, pale bluish-green in general; ribs (7-)8-12(-15), sharply furrowed, blunt, low, somewhat crenate; areoles 1-2cm apart, somewhat indented, with V-shaped furrows above, white-felted, with 8-10(-12) straight, spreading, white or brown radial spines up to 12(-25)mm long, and 4-5 erect, brown central spines up to 2(-6)cm long and bulbous at the base, in general spines dark brown to black at first, later grey. Flowers near apex, bell-shaped, narrowly campanulate, 4-6cm long, white or red, pale pink outside, usually nocturnal; externally scaly and felty; ovary bearing small scales subtending wool and bristly spines. Fruit globular, 3-4cm across, red, edible, very spiny when young; seeds large, mostly flattened, ovoid or cap-shaped, seedcoat glossy to dull black, smooth or verrucose.

Puebla, Oaxaca; Mexico (Britton & Rose 1963; Cullmann et al. 1986; Haustein 1991).

Slow growing; cuttings may be slow to root [as with S. beneckei]. Likes moderately poor soil, very good drainage, moderate sun. S. beneckei needs warmth in winter and is quite frost-sensitive; S. eruca likes sand added to the soil, plenty of sun, and careful watering, as well as a prostrate habit. All species like being planted in the ground, for full root development (Trout & Friends 1999; pers. obs.).

STENOSOLEN

(Apocynaceae)

Stenosolen heterophyllus *(Vahl) Markgr.* **(S. eggersii** *Markgr.***; S. grandifolius** *Markgr.***; S. holothuria** *Markgr.***; S. stenolobus** *(Müll. Arg.) Markgr.***; Peschiera cuspidata** *Miers***; P. diversifolia** *Miq.***; P. heterophylla** *(Vahl) Miers***; P. laevifructa** *Allorge***; P. puberiflora** *Miers***; P. stenoloba** *(Müll. Arg.) Miers***; P. tenuiflora** *Poepp.***; Tabernaemontana heterophylla** *Vahl***; T. stenoloba** *Müll. Arg.***; T. tenuiflora** *(Poepp.) Müll. Arg.***; T. unguiculata** *Rusby***)** – sanango, tsecat

S. heterophyllus is used in both Brazil and Peru. The Mayna Jivaro chew bark scrapings for toothache, and Brazilian natives give a leaf tea to elderly people who are "slow and forgetful" (Schultes & Raffauf 1990).

S. heterophyllus trunk bark has yielded 5.1% alkaloids, consisting of 8% olivacine, 0.15% *ibogaine*, 0.9% *ibogamine*, 0.2% *coronaridine*, 0.8% affinisine [CNS depressant, analgesic], 1% *voacamine*, 0.7% descarbomethoxy-*voacamine*, 1.4% tabernamine, 0.4% 7-OH-*voacangine*-indolenine, 0.01% pericalline, 1.3% *vobasine*, 0.08% vallesamine and 0.03% tetrahydro-3,14,4,19-olivacine. Leaves yielded 0.4% alkaloids, consisting of 3% ervafoline, 0.6-3% ervafolidine, 1.5-3% 19'-OH-ervafolene, 1.1-3% 19'-OH-ervafoline, 0.1-3% 19'-OH-ervafolidine, 2.4-3% 19'-OH-epi-3-ervafolidine, 0.1-3% ervafolene, 1.2% 7-OH-*voacangine*-indolenine, 2.8% pandine, 1.3% voaphylline, 1.25% *voacangine* and 1.1% pandoline (Kan et al. 1984).

Stenosolen heterophyllus is a tree or erect shrub to c.2m tall; youngest twigs hairy; dichasially-branched immediately above leaf-nodes, out of axils of small scales alternating with leaves. Leaves opposite, unequal, papery, almost sessile, the two of each node +- unequal in size, obliquely elliptic, abruptly acuminate at apex, at base rounded on one flank, narrowed on the other, glabrous, 7-15 x 2.5-5cm, secondary nerves strongly bent, 10-12 on each side; intrapetiolar glands present. Inflorescence cymose, terminal or pseudo-axillary, few-flowered, bracteate, 2-3cm long; peduncles and pedicels very slender; calyx teeth glabrous, lanceolate, acute, 1mm long, slightly diverging, pluriglandular internally; corolla white, salverform, tube 1cm long, 1mm wide, gradually widening somewhat at base, otherwise constricted from base to throat, glabrous externally, with long straight hairs internally, lobes 5mm long, glabrous, oblong, acuminate, slightly oblique; stamens inserted near base of tube; anthers basal, sagittate, 4mm long, with spreading tails, bearing pollen only in middle portion. Ovary apocarpous, without disc; style split; stigma head globose with 2 short apical tips, and somewhat remote horizontal basal skin-ring. Fruit distinctly apocarpous, mericarps spreading, crescent-shaped or almost obovate, c.3.5cm long, 1cm diam., orangeish, densely covered with numerous pyramidal 2mm-high protuberances; seeds many, dark-brown, ellipsoid, longitudinally ribbed, ring-shaped aril around hilum.

At forest edges; n. Brazil, Guyana (Pulle 1966), Peru.

STEPHANOMERIA

(Compositae/Asteraceae)

Stephanomeria pauciflora var. pauciflora *(Torr.) A. Nelson* **(Lygodesmia pauciflora** *(Torr.) Shinners***; Ptiloria pauciflora** *(Torr.) Raf.***; P. runcinata** *(Nutt.) Davidson et Moxley***; S. cinerea** *(Blake) Blake***; S. neomexicana** *(Greene) Cory***)** – desert straw, desert skeletonweed, wire-lettuce, brownplume wire-lettuce, hehe imixáa, posapátx camoz

The roots of this herb are used by the Kayenta Navajo of N. America

as a narcotic (Ott 1993). I have been able to find no other ethnobotanical or chemical information regarding this plant.

Stephanomeria pauciflora var. pauciflora is a perennial, rounded herb with intricately much-branched stems, mostly divaricate and stiffish, 30-60cm tall from a woody rootstock, base of stems sometimes slightly woody. Leaves glabrous, pale green, basal leaves narrowly oblong, lanceolate or oblanceolate, 3-7cm long, remotely runcinate-pinnatifid, rarely over 1.5cm wide, including lobes, upper leaves reduced, linear to subfiliform, entire, often +- revolute, upper-most mere scales so branchlets form an open, nearly leafless system. Inflorescence of few-flowered heads, solitary on axillary or terminal short peduncles; involucres 8-10mm long at anthesis; bracts linear to lanceolate, acute or slightly callus-tipped; flowers mostly 3-5, ligules equal, flesh-coloured, 5-6mm long, opening early in morning and usually closing before noon; receptacle flat, naked or alveolate. Achenes linear, oblong or slightly turbinate, 3-4mm long, strongly 5-angled, striate between angles, minutely roughened but rarely rugose, truncate; pappus bristles 12-25, sordid to tawny or faintly rufous, 6-7mm long, plumose above basal ¼, lateral capillary hairs 1.5-2.5mm long, bases slightly dilated. Fl. almost all year.

Along washes, gravelly bajadas, plains and arid mesas; Colorado to Mojave Deserts, California, to Kansas, Texas, northern Sonora and central Baja California (Shreve & Wiggins 1964).

STETSONIA

(Cactaceae)

Stetsonia coryne *(Salm-Dyck.) Br. et R.* **(Cereus coryne** *Salm-Dyck.***; C. coryne** *Otto***)** – argentine toothpick

S. coryne was shown to contain 0.001-0.05% alkaloids [w/w], of which c.1-10% was *mescaline*, more than 50% 3-MeO-*tyramine* [homovanillylamine], c.10-50% *tyramine*, c.1-10% N-methyl-*tyramine* and traces of *DMPEA*, *anhalonidine* and anhalidine [6,7-dimethoxy-8-OH-2-methyl-THIQ] (Agurell et al. 1971); an earlier study found 1% [d/w] coryneine [N,N,N-trimethyl-*dopamine*; oxo-candicine] (Trout ed. 1999, citing Reti et al. 1935 [full paper]). The Chemical Abstracts entry for Reti et al. (1935) states only that a new, impure alkaloid was obtained, with physiological effects resembling those of candicine and *nicotine* (Reti et al. 1935).

Stetsonia coryne is a massive tree-like cactus 5-8m tall, with a short trunk up to 40cm thick, branching out into up to 100 and more branches, up to 60cm long and 9-10cm thick; ribs 8-9, 1-1.5cm deep, obtuse, more or less crenate; areoles felted, with 7-9 subulate, spreading, unequal radial spines 3cm long, and 1 subulate central spine c.5cm [or more] long. Flowers solitary at upper areoles, 12-15cm long, funnel-shaped, wide-opening, white; inner perianth segments white, oblong-lanceolate, acute, spreading; outer perianth segments broad, green, obtuse; pericarpel densely covered with broad, ciliate scales, receptacle tube with broader, more widely spaced scales; ovary oblong-globose, densely covered by ciliate, abruptly subulate-tipped membranous scales; stamens numerous, not exserted; anthers large, oblong; style stout; stigma lobes many, linear. Fruit stout, ovoid, lime light-green, similarly covered with scales, floral remains deciduous leaving brown scar; seeds obliquely elongate-ovoid, with broad, lateral hilum, seedcoat black, coarsely verrucose.

N.w. Argentina, Bolivia (Britton & Rose 1963; Haustein 1991).

Prefers rich, well-drained soil, little watering, and full sun; slow-growing. Can be frost sensitive, depending on the length of exposure and the hardiness of the individual; frosts and over-watering can cause orange colouration at the base, which usually leads to fatal rot (Trout & Friends 1999).

STICTOCARDIA

(Convolvulaceae)

Stictocardia tiliaefolia *Hallier* **(S. tiliifolia** *(Desreuz) Hallier fil.***; S. campanulata** *(L.) Merr.***; Argyreia campanulata** *(L.) Alston***; A. tiliifolia** *(Desr.) Wight***; Convolvulus campanulatus** *(L.) Spreng.***; C. gangetinus** *Roxb.***; C. grandiflorus** *L. f.***; C. melanostictus** *Schlecht***; C. tiliifolius** *Desr.***; Ipomoea benghalensis** *Roem. et Schult.***; I. campanulata** *L.***; I. gangetica** *Sweet***; I. grandiflora** *(L. f.) Lam.***; I. pulchra** *Blume***; I. tiliifolia** *(Desr.) Roem. et Schult.***; Rivea campanulata** *(Spreng.) House***; R. tiliifolia** *(Desr.) Choisy***)** – tugelmi, goili, kuginiballi, karihuginniyahambu, wa damudamu

The generic name for this plant comes from the Greek 'stiktos' ['punctured' or 'spotted'] and 'kardia' ['heart'], referring to the appearance of the leaf (Wagner et al. 1990). In India, the plant is said to be used as an antidote to snake poison, though neither roots or leaves have proven active in this regard (Kirtikar & Basu 1980). In Fiji, the plant is decocted and drunk after childbirth (Cambie & Ash 1994).

Recent human bioassays have revealed the seeds to have psychoactivity and potency similar to **Argyreia** nervosa, with 8 seeds of some material being an active dose (Torsten pers. comm. 1999).

S. tiliaefolia seed has yielded 0.14-0.15% alkaloids, consisting of [as % of total alkaloids] 48-49% *lysergol*, 24-26% *elymoclavine*, 3.2-3.6% *ergonovine*, 2-2.2% *penniclavine*, 1.8-2% iso-*penniclavine*, 1.5-1.8% ergometrinine, 1.5-1.7% isolysergol, 1.4% *ergine*, 1.5% *chanoclavine*-I, 1.2% *chanoclavine*-II, 1.1% α-dihydrolysergol, 1% iso-*ergine*, *festuclavine* and 7.5-18% unidentified alkaloids (Chao & Der Marderosian 1973a; Der Marderosian 1967); as well as sterolin and β-sitosterol glucoside (Rastogi & Mehrotra ed. 1990-1993). Leaves and roots have yielded calystegines [see **Convolvulus**] (Schimming et al. 1998).

Stictocardia tiliaefolia is a herbaceous liana; stems herbaceous at tips, becoming woody with age, up to 5m or more long. Leaves cordate to cordate-ovate, 8-25cm long, both surfaces glabrate, lower surface with numerous scattered pellucid-glandular dots, margins entire, apex acute to short-acuminate, base cordate. Flowers usually solitary, axillary, occasionally 1-3 in cymes, peduncles usually shorter than leaves; sepals subequal, suborbicular, 1-2cm long, puberulent, becoming glabrate; corolla reddish-purple with a darker centre, funnelform, 8-10cm long. Fruit indehiscent, globose, 2.5-3cm long, surrounded by calyx that eventually disintegrates, leaving the vascular framework; seeds 1-4, greyish-brown, obovoid, 8-9mm long, pubescent with minute hairs.

Dry disturbed areas, 3-220m; pantropical (Wagner et al. 1990), including Northern Australia [Northern Territory, Queensland] (Hnatiuk 1990), India east to Polynesia (Cambie & Ash 1994).

STIPA

(Gramineae/Poaceae)

Stipa inebrians *Hance* **(Achnatherum inebrians** *(Hance) Keng***)** – needle grass

Stipa robusta *(Vasey) Scribn.* **(S. vaseyi** *Scribn.***; S. viridula var. robusta** *Vasey***; Achnatherum robustum** *(Vasey) Barkworth***)** – needle grass, green needle grass, robust needle grass, popoton sacaton ['sleepy grass']

Stipa sibirica *(L.) Lam.* **(S. brandisii** *Mez***; S. confusa** *Litv.***; Achnatherum extremiorientale** *(Hara) Keng***; A. sibiricum** *(L.) Keng***; Avena sibirica** *L.***)**

Stipa viridula *Trin.* **(S. nuttalliana** *Steud.***; S. robusta** *Nutt. ex Trin. et Rupr.***; S. spartea** *Trin. ex Hook.***; Nassella viridula** *(Trin.) Barkworth***)** – needle grass

These grasses are known to cause intoxications in stock animals, which are generally due to endemic infestation of the seeds and other parts of the plants with an **Acremonium** sp. or related fungus [see **Festuca**, **Lolium**].

S. inebrians has been responsible for intoxicating cattle in Mongolia (Bruehl et al. 1994; Hance 1876), as has S. sibirica in northern Asia. In N. America, S. robusta caused some travelling problems with early Western settlers, as in areas where it was abundant their horses would graze on it and fall into a "profound, nearly stuporous sleep". Only grass from the Sacramento-White Mountain area [near Cloudcroft, New Mexico] is said to have this effect, though in Guatemala, the grass is taken by humans to induce sleep. S. viridula, which occurs in both Europe and N. America, has only been reported to be intoxicating in Europe (Cheeke 1995; Emboden 1979a; Kaiser et al. 1996; Pammel 1911; White et al. 1992; White & Morgan-Jones 1987).

A sterile, unidentified **Acremonium** sp. has been isolated from S. inebrians. A similar endophytic fungus has been isolated from S. robusta collected from the area mentioned above [also unidentified – intermediate between A. coeniphialum and A. starrii], as well as what appears to be A. chisosum. S. eminens has also been shown to support A. chisosum in the leaf sheaths, stems, and seeds. Of 13 North American Stipa spp. examined, only S. eminens, S. lobata [some specimens endophyte-free], S. robusta and S. viridula contained endophytes, which were macroscopically similar. S. viridula only contained an endophyte in specimens from central Colorado, where it grows with S. robusta (Bruehl et al. 1994; Kaiser et al. 1996; White & Morgan-Jones 1987).

One human subject experimented with eating 9 seeds of S. robusta; mild psychedelic and stimulant effects began after 1-1.5hrs. The subject then lay down in the dark and tripped calmly for another 30mins before drifting off to sleep. No negative side-effects were said to have occurred (DeKorne 1994). Another individual found 1tsp of seed, free of chaff and seed-hairs, to be psychoactive. Seeds that have been thawed after freezing are apparently inactive (Torsten pers. comm. 2001). Most people who have experimented with the seeds experience predominantly sedative or tranquillising effects, and little true psychedelic activity. One person has also reported on their experiments with eating fresh S. robusta leaves, chewing the foliage and occasionally spitting it out to take another mouthful; similar effects to those from consuming the seeds were experienced. It is claimed that the dried grass is inactive (Anon. 1999; Green 1999b; pers.

comm.), though in animal feeding tests, this was not the case (Epstein et al. 1964). However, samples stored for long periods would be expected to lose potency rapidly. Oddly, most human bioassays have focused on the seeds, with the false belief that the grass itself does not contain the endophyte or the psychotropic alkaloids.

S. inebrians has yielded a psychoactive alkaloid, stipatoxin (Bruehl et al. 1994).

S. robusta infected with an **Acremonium** sp. has yielded 0.002% *ergine*, 0.0008% isoergine, 0.00003% 8-OH-*ergine*, 0.0015% *chanoclavine-I*, 0.0007% *ergonovine* and 0.0018% N-formylloline (Petroski et al. 1992). Before the presence of alkaloids was noted, grass from near Ruidoso, New Mexico, was found to contain 1.2% diacetone alcohol [4-OH-4-methyl-2-pentanone], which was shown to have hypnotic and CNS-depressant activity in animals (Epstein et al. 1964).

Stipa robusta is a large, tufted perennial grass, 1-2m tall, growing in dense clumps. Leaves involute, setaceous, large, flattened, margins rolled inwards on upper surface, covered with bristly hair, flat to U-shaped, 4-8mm x 20-50cm; sheath glabrous, villous at throat, covered with long, soft hairs; ligule 2-4mm long. Panicle narrow, compact, often +- interrupted below, up to 30(-45) x 2cm, lower nodes of the panicle villous, the branches appressed; spikelets 1-flowered, c.1cm long, on short pedicels, attenuate into fine, soft point, disarticulating obliquely above glumes, leaving a bearded, sharp-pointed callus attached to base of floret; glumes firm, narrow, gradually acuminate, usually hyaline, the first usually 3-nerved, nerves inconspicuous, empty glume nearly equal in length to spikelets; lemma 6-8mm long, narrow, terete, strongly convolute, terminating in prominent awn; awn 2-3cm long, twisted below, obscurely twice bent, geniculate; palea enclosed in lemma.

Dry plains and hills, dry open woods; Colorado to w. Texas, Arizona and n. Mexico, 1670-2740m (Barnard & Potter 1984; Hitchcock 1951; Pammel 1911).

Of the **Acremonium sp.** – hyphae in the lower 2-3cm of seedlings grown aseptically from infected seed were intercellular, c.2µm diam., mostly straight, unbranched, some moderately convoluted [some convoluted segments up to 3.5-4.4µm diam.]. Considerable variation in conidial shapes occurred, and the average spore lengths did not conform to other described species (Kaiser et al. 1996).

STREPTOPUS

(Liliaceae)

Streptopus amplexifolius *(L.) DC.* **(Uvularia amplexifolia** *L.***)** – dead person's berry, twisted stalk, white mandarin

The Tlingit of Alaska process the roots of this lily into a decoction, which is drunk as an intoxicant (Lipp 1995). The Cherokee cook the foliage of S. amplexifolius and S. roseus to eat as a vegetable (Hamel & Chiltoskey 1975).

Chemistry of this plant is obscure.

Streptopus amplexifolius is a perennial herb springing from a rhizome, often branched, 40-100cm tall with a glabrous stem. Leaves alternate, ovate-oblong, varying to ovate or ovate-lanceolate, acuminate, cordate and clasping at base, entire or very minutely toothed, the principal leaves 6-12 x 2-5.5cm. Free portion of the peduncle and pedicel together 3-5cm long, jointed at about 2/3 of its length, above the joint 1(-2)-flowered, abruptly deflexed or twisted; perianth campanulate to rotate, segments separate to the base, essentially alike, greenish-white, c.1cm long, spreading from near the middle, the outer whorl usually slightly wider, 6-toothed at margin; stamens 6, adnate to base of perianth; filaments widened at base; anthers oblong to linear, 1-pointed. Ovary 3-celled with several ovules; style slender, 3-cleft, 3-lobed or entire; stigma entire or barely 3-lobed. Fruit a red, many-seeded berry, usually ellipsoid. Fl. Jun.-Jul.

In rich, moist woods; Greenland to Alaska, s. to Massachusetts, New York, Michigan, Wisconsin and Minnesota, in the mountains to N. Carolina, in the west to Arizona and New Mexico (Gleason 1952).

STRYCHNOS

(Loganiaceae)

Strychnos brachiata *Ruiz. et Pav.* – cabalonga negra

Strychnos cabalonga *Hort. Lind.* – cabalonga negra

Strychnos icaja *Baill.* **(S. alnifolia** *Baker***; S. dewevrei** *Gilg***; S. dundusanensis** *De Wild.***; S. inocua** *Delile***; S. kipapa** *Gilg***; S. mildbraedii** *Gilg***; S. pusilliflora** *S. Moore***; S. triclisioides** *Baker***; S. unguacha** *A. Rich***; S. venulosa** *Hutchinson et M.B. Moss***)** – icaja, benge, bondo, mbondo, mbundu

Strychnos nux-vomica *L.* **(S. colubrina** *Wight***; S. lucida** *R. Br.***; S. spiraena** *Dop***; S. vomica** *St. Lag.***)** – strychnine tree, nux-vomica, poison nut, crow tree, Quaker button, ma qian zi, fan mu pieh, ma ts'ien tse, kachita, krishnabana, kulaka, vishamushti, jahar, kuchla

Strychnos tessmannii *Perk.*

Strychnos spp.

These plants, particularly S. nux-vomica, are best known today as sources for *strychnine* and related indole alkaloids. Contrary to popular belief, there has been no *strychnine* found in mushrooms, cacti, or any other living things that I am aware of, unless purposely introduced as an adulterant. Strychnos spp. seeds are rarely employed today except in homoeopathic doses, due to the danger associated with their use. They have generally served as a nerve tonic or aphrodisiac, though they have also been used as a poison for both rodents and stray dogs in India. In some parts of India, seeds of S. nux-vomica are eaten habitually as an aphrodisiac. Some distillers of bootleg 'arrack' liquor add the seeds to the drink to make it more potent. The seeds have also been given to horses as a tonic (Chopra et al. 1965; Nadkarni 1976). Ayurvedists consider S. nux-vomica to be bitter, acrid, pungent and heating in energetics; the seeds are used as an appetiser and astringent to the bowels, as well as to treat fever, leucoderma, itching, blood diseases, piles, ulcers, urinary discharges, jaundice and anaemia. The seeds are generally used in Indian folk medicine to treat paralysis, weakness and ulcers with maggots; they act as a nervine, spinal stimulant, diuretic and emetic (Kirtikar & Basu 1980; Nadkarni 1976). In Nepal, the seeds are used to treat paralysis, rabies, menstrual problems, and as a digestive tonic. The seeds of the Indian S. potatorum ['clearing nut'] are put in water jars to cause impurities to sink to the bottom (Bremness 1994). The Cambodian 'shlain' tree remains unidentified to my knowledge, but is suspected of being S. nux-vomica; its wood is grated to shavings which are mixed with **Cannabis** and smoked, resulting in stronger and more psychedelic effects (Rätsch 1998).

According to a Tikuna shaman of s. Colombia, the rasped bark of S. tessmannii, if added to the fermented 'chicha' beverage [see *Methods of Ingestion*], can cause permanent insanity (Altschul 1967). S. cabalonga and/or S. brachiata are thought to represent 'cabalonga negra', a magical and potently psychoactive seed valued and used in Colombia. In n. Peru, S. ignatii is used as 'cabalonga' [see also **Jatropha** and *Endnotes*]. In w. Africa, the bark of S. icaja is sometimes taken with **Tabernanthe** iboga (Rätsch 1998). The people of Sette Cama have been reported to use a bark decoction of S. icaja in their initiation ceremonies; the brew is said to render the initiate unconscious for up to 3 days (Laydevant 1932). The root bark and/or trunk bark have also been used an an ordeal poison in central Africa. S. spinosa bark has been used for this purpose in e. Africa, as has the root bark from S. densiflora [Cameroon] and S. samba [c. Africa]. S. samba fruits have also been used to poison fish (De Smet 1998). In Papua New Guinea, S. minor is sometimes used as a hunting stimulant for dogs, as well as to make them fierce (Thomas 2001a).

Strychnos spp. have been used as major ingredients in dart poisons for hunting in Java, Borneo, Malaya, and other parts of Indo-China (Bisset 1966; Bisset & Woods 1966). Barks from more than 12 species of Strychnos are used in making 'curare' dart poisons in S. America (Schultes & Raffauf 1990), including S. solimoesana ['ira'], the stem-bark of which is used by the Jamamadi of Brazil, along with stem-barks from Curarea toxicofera, Guatteria cf. megalophylla, and a Fagara sp. [see *Endnotes*]. "S. solimoesana-based poison is said to be one of the most powerful and effective paralyzing curares" (Prance 1972). Strychnos spp. root bark is also used to make arrow poison in c. Africa, such as S. usambarensis [S. micans], which is used by the Nyambo of Rwanda and Tanzania (De Smet 1998). In n. Australia, the Ngarinyman use S. lucida ['naalij'] to stun fish

(Smith et al. 1993).

In very small amounts, S. nux-vomica seed acts as a CNS-excitant, nerve stimulant, aphrodisiac and respiratory stimulant, and has been suggested to even be a powerful psychedelic in moderate doses; at higher doses, overstimulation of the nervous system results in tetanic convulsions and respiratory depression; coma and death may occur. Seeds may be taken with great caution 0.1g at a time, or 0.2g a day. A fatal dose of seeds may be 0.7-2.7g. To treat poisoning, emetics and large doses of charcoal in water should be given, as well as inhalation of chloroform or amyl nitrite between convulsions (Chopra et al. 1965; Huang 1993; Nadkarni 1976; Rätsch 1990, 1992). Oddly, there has even been a popular song ['Strychnine', by The Sonics] seemingly espousing *strychnine* as a psychotrope! Lyrics to the song include "You may think it's funny that I like this stuff, but once you've tried it you can't get enough"; "if you listen to what I say you'll try *strychnine* some day"; and "makes you tough, it'll make you shout, it'll even knock you out"!

S. icaja bark has yielded 6.6% *strychnine*; this species is the richest known source of *strychnine* (Buckingham et al. ed. 1994).

S. nux-vomica seed has yielded 1.5-5% alkaloids [following figures from one analysis given as % in pericarp; % in pulp], predominantly *strychnine* [0.169; 0.04], with a smaller amount of *brucine* [0.065; 0.03], as well as 4-OH-*strychnine* [0.0007; 0.002], pseudostrychnine [0.002; 0.003], pseudobrucine [0.008; 0.003], *strychnine* N-oxide [0.005; 0.002], *brucine* N-oxide [0.016; 0.009], N-methyl-sec-pseudobrucine, icajine [0.006; 0.002], vomicine [0.091; 0.013], novacine [0.02; 0.018], N-methyl-sec-pseudo-β-colubrine [0.0007; -], α- and β-colubrine [between *strychnine* and *brucine* in potency][0.004; -] and struxine; also found are the glycoside loganin, and *chlorogenic acid*. The pericarps also contained another 0.092% alkaloids, a mix of *strychnine*, *brucine*, and their N-oxides; pulp yielded another 0.105% alkaloids, a mix of the same compounds. Leaves have yielded *strychnine*, *brucine* and strychnicine; bark yielded mostly *brucine*, with traces of *strychnine* [young bark 3.1% *brucine*, old bark 1.68% *brucine*]; wood has yielded *brucine* and *strychnine*; old roots have yielded 0.99% alkaloids, consisting of 0.2% *brucine* and 0.71% *strychnine* (Bisset & Phillipson 1976; Chopra et al. 1965; Henry 1939; Huang 1993; Morton 1977).

S. usambarensis root bark is unusual due to its lack of *strychnine* and related alkaloids, unlike most other Strychnos spp. used for arrow poisons in Africa; alkaloids found to be present include usambarensine [some *atropine*-like effects, spasmolytic], 3,4-dihydrousambarensine, 6,7-dihydroflavopereirine, calebassine, C-curarine, afrocurarine, dihydrotoxiferine, *harman* (De Smet 1998), melinonine F and 2-methyl-β-carbolinium quaternary salt (Shulgin & Shulgin 1997).

Other Strychnos spp. have yielded, besides *strychnine*-like indole alkaloids, some β-carbolines. S. elaeocarpa bark has yielded strychnocarpine [2-methyl-3,4-dihydro-β-carbolone-1]; S. floribunda has yielded strychnocarpine; S. johnsonii rootbark has yielded noreleagnine [1,2,3,4-tetrahydro-β-carboline], *norharman* and *harman*; S. melinoniana has yielded melinonine F [1,2-dimethyl-β-carbolinium salt]; and S. potatorum rootbark has yielded *norharman* (Allen & Holmstedt 1980; Shulgin & Shulgin 1997).

Strychnos nux-vomica is a deciduous tree to 30m tall, often with short, sharp, strong axillary spines; bark thin, grey, smooth or rough with lenticels. Leaves opposite, 7.5-15 x 4.5-7.5cm, broadly elliptic, acute, obtuse, or shortly acuminate, glabrous and shining, 5-nerved, the lateral pair often faint, base usually rounded; petioles 6-13mm long. Flowers numerous, greenish-white, in terminal pedunculate pubescent compound cymes; bracts small; peduncles and pedicels short, pubescent; calyx 2.5mm long, pubescent outside, segments 5, lanceolate, acute, 1.5mm long; corolla campanulate or hypocrateriform, a little less than 1.3cm long, 5-lobed, glabrous or nearly so outside, tube cylindric, hairy inside below, throat glabrous, lobes 4mm long, narrowly oblong, acute, valvate; stamens 4-5, inserted in throat of corolla; filaments short, filiform; anthers ovate, with distinct parallel cells. Ovary glabrous, 2-celled throughout, or 1-celled in the upper part; ovules many in each cell; style glabrous, long or short; stigma capitate or obscurely 2-lobed. Fruit a globose berry, 2.5-7.5cm diam., slightly rough but shining, orange-red when ripe, with hard rind; seeds usually many, discoid, c.2cm diam., much-compressed, concave on one side and convex on the other, clothed on both sides with very fine appressed grey silky hairs radiating from the centre.

In deciduous forests, sandy soil in dry forests, hilly areas; India, Sri Lanka, Indo-China, Laos, Burma (Kirtikar & Basu 1980).

SWAINSONIA

(Leguminosae/Fabaceae)

Swainsonia galegifolia *(Andr.) R. Br.* **(S. coronillaefolia** *Salisb.***)** – Darling pea, smooth Darling pea, red Darling pea, indigo plant

Swainsonia spp. – desert pea

This genus of Australian herbs has often been implicated in poisoning sheep, cattle and horses, the affected animals being referred to as 'pea-struck'. Effects have been compared to those of some Astragalus spp. and **Oxytropis** spp. ['locoweeds' from N. America – see also *Endnotes*], without the abortive and deformative symptoms. Poisonings generally occur in the dry season, following rains in early spring or autumn, or when fruit of the plant is mature, and may last 5-6 months. Intoxications in stock manifest gradually over days or weeks, and symptoms include staring eyes, or an agonised expression, stiffness, slight staggering, trembling of head and limbs, followed by motor incoordination and apparent distortion of perception of physical dimensions. Some animals become hyperexcitable, and may fall over if startled. Several species have caused illness and death from prolonged feeding [S. canescens, S. luteola, and S. procumbens] and these plants probably all contain similar compounds [see below]. Deaths are generally not reported from the species causing more noticeable CNS intoxication [which still does not manifest until after prolonged feeding]. It is probable these species do not contain the toxic compounds in appreciable amounts, or that they are located primarily in the mature fruits. Species causing predominantly CNS symptoms include S. galegifolia, S. oroboides and S. swainsonioides [which is very similar to S. procumbens]. Some animals even develop a craving for S. galegifolia and seek it out above other foods. Interestingly, S. cadelli has been credited with killing bees in Coonabarabran, NSW (Everist 1974; Hurst 1942; Schultes & Hofmann 1980). In inland n.e. Australia, indigenous people have used S. galegifolia [whole plant] as a poultice for bruises and swellings (Lassak & McCarthy 1990).

S. canescens contains swainsonine, which is a toxic α-mannosidase inhibitor (Buckingham et al. ed. 1994). Poisoning from plants containing it results in toxic symptoms including coarse faeces, upper respiratory congestion and infections, cataracts, profound mental retardation and other nasty effects (Everist 1974). S. canescens also contains (S)-canavanine – see **Canavalia**, as do some other Swainsonia spp. [S. greyana, S. maccullochiana, S. phacoides] (Bell et al. 1978).

S. galegifolia contains (S)-canavanine (Bell et al. 1978), as well as the alkaloid spherophysine; the hydrolysed flower yields a flavonoid, delphinidin (International... 1994). In independent testing, leaves picked in August [from a sample growing in the northern hemisphere] tested positive for the presence of what was tentatively identified as *N-methyltryptamine*, with lesser amounts of *DMT*; *N-methyltryptamine* was also tentatively detected in stems. A sample taken in November appeared to contain only *DMT* (Heffter 1996). In plants from Brisbane, Queensland [harv. Nov.], mature fruits, leaf and stem tested positive for alkaloids; immature fruits and roots tested negative. Leaf and stem from Clifton, Queensland, harvested in the same month, also tested alkaloid-positive, with negative assays for the roots (Webb 1949). In another alkaloid screening, leaves gave negative results (CSIRO 1990).

S. luteola from Queensland, harvested November [whole plant], tested positive for alkaloids (Webb 1949).

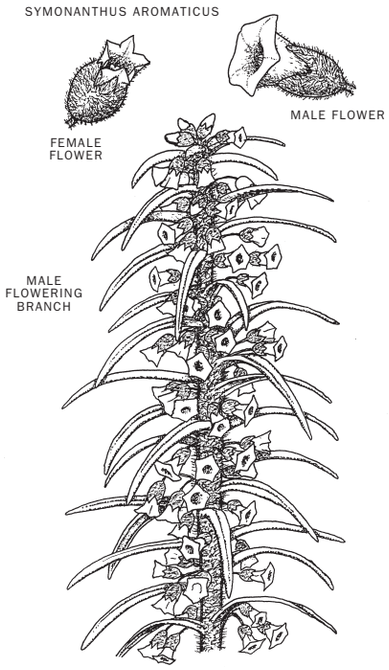
Swainsonia galegifolia is a perennial herb to c.1m tall; stems glabrous. Leaves usually imparipinnate, mostly 5-10cm long; pedicels glabrous, usually more than 5mm long, sometimes shorter; 21-29 leaflets, narrow-obovate to elliptic, the lower 8-15mm long, 3-5mm wide, apex obtuse to emarginate, both surfaces glabrous; stipe mostly 1-2mm long; stipules 2-5mm long, mostly triangular to triangular-acuminate. Inflorescences axillary 15-20 flowered racemes; flowers mostly 12-15mm long; bracts to 10mm long, bracteoles small; calyx +- campanulate, glabrous, teeth often much shorter than tube; corolla white, pink, purple, yellow, orange or dark red; keel apex obtuse and obscurely lipped, tip horizontal or at most a little raised; standard usually longer than wings, sometimes longer than keel; wings shorter than keel; stamens diadelphous, of alternating lengths; anthers uniform. Ovary usually +- stipitate; style tip straight or +- incurved, usually bearded lengthwise along the upper part, sometimes with a few hairs behind the stigma; stigma terminal or subterminal. Pod elliptic, mostly 20-40mm long, glabrous, usually dehiscent, sometimes inflated, 1-locular or longitudinally 2-locular; stipe often more than 10mm long; seeds few to numerous, aril not present.

Similar to S. greyana, but with smaller leaves and flowers; S. greyana also has a white-wooly calyx rather than a glabrous one.

Widespread in a variety of habitats; Australia [e. NSW drier forests, also in Vic. and Qld] (Costermans 1992; Harden ed. 1990-1993)

SYMONANTHUS

(Solanaceae)



Symonanthus aromaticus *(C. Gardner) Haegi* **(Anthocercis aromatica** *C. Gardner***)**
Symonanthus bancroftii *(F. Muell.) Haegi* **(Isandra bancroftii** *F. Muell.***)**

This Australian genus of only two species is very closely related to **Anthocercis**, and its members contain small amounts of similar tropane alkaloids.

S. aromaticus [mature specimen, harv. Jul. from near Newdegate, New South Wales] aerial parts yielded 0.01% alkaloids, and roots yielded 0.03% alkaloids; both parts contained *hyoscine*, apo-*hyoscine* and tiglic acid or tigloyl esters [these latter compounds being dominant in roots] (Evans & Ramsey 1983).

S. bancroftii has not been chemically analysed, but probably contains similar tropane alkaloids.

Symonanthus aromaticus is an erect, dioecious shrub to 1.3m; branches, lower surface of leaves and outer surface of corolla moderately to densely villous with non-glandular, forked to much-branched hairs and smaller glandular hairs; upper surface of leaves, pedicels and calyx sparsely to moderately pubescent mainly with glandular hairs, with non-glandular hairs also present. Leaves alternate, crowded, narrowly triangular to linear, sessile, usually 20-45 x 1.5-5mm, entire, margins narrowly revolute. Flowers solitary or in 2-3-flowered cymes, terminal or on short lateral branches, subtended by pairs of opposite bracts. Male flowers – pedicels 3-7.5mm long; calyx campanulate to cupular, 5-lobed, 4-5mm long; corolla regular, 7-8mm long, narrowly tubular with erect or spreading limb, tube 6-7mm long, white with purple striations in tube, limb 5-lobed, the lobes short and volutive in bud; stamens (3-)4-5, 3-6mm long, equal, inserted at base of corolla-tube; staminode sometimes present; anthers bilocular, cohering, dorsifixed, dehiscing by longitudinal slits; ovary 0.7-0.9mm long, infertile. Female flowers – similar but smaller; pedicels 1-3.5mm long; calyx 4-5mm long; corolla c.6mm long, the tube 5mm long; stamens 4(-5), 2-3mm long, infertile; ovary bilocular, 1.5mm long; ovules 6-10; stigma capitate, very shortly bilobed. Fruit a smooth capsule, broadly ovoid-ellipsoid to subglobular, 3.5-4.5mm long, opening apically by 4 valves, +- enclosed by calyx; seeds c.2mm long, ellipsoid.

Scattered populations in sandy soil, usually in disturbed habitats in mallee or woodland; endemic to s.w. Western Australia, in the south-eastern wheat-belt region (Haegi et al. 1982).

SYZYGIUM

(Myrtaceae)

Syzygium aromaticum *(L.) Merr. et Perry* **(Caryophyllum aromaticum** *L.***; Eugenia aromatica** *(L.) Baill., non. Berg***; E. caryophyllata** *Thunb. nom. illeg.***; E. caryophyllus** *(Spreng.) Bullock et Harris***)** – clove tree, Zanzibar red head, devakusumum, laung, kirambu, mekhaka, karanaphul, li-shi

'Cloves', the dried flower buds of S. aromaticum, were known and used by the Chinese from at least 266BC as a spice and medicine; they are an ingredient of 'Chinese five spice'. The Romans came to use them as their empire spread, but in 1500AD, more frequent visits to the Indies by European traders made the spice better known. Cloves are also an ingredient of 'garam masala', and are often included in mulled wines. They are often used to relieve toothache due to their anaesthetic properties. Some Asian cigarettes contain cloves, which numb the throat and allow one to smoke more. Their use as an aphrodisiac spice is ancient, and in China they were chewed as a breath-freshener before making love. In Tibet, cloves are used in psychiatric medicine, and are said to act on the 'life-vein' ['srog rtsa'] from whence consciousness originates, which is connected to the heart. Clove essential oil is analgesic, aphrodisiac, stimulant, spasmolytic, antiseptic, antibiotic, anthelmintic, antiviral, stomachic, antiemetic, antirheumatic, antineuralgic, antihistaminergic, antioxidant, antimycotic, carminative, counter-irritant, expectorant, larvicidal, insecticidal and vermifugal; it is effective against infection by coli bacilli, streptococci, staphylococci and pneumococci (Bremness 1994; Clifford 1984; Lawless 1995; Mabey et al. ed. 1990; Nadkarni 1976; Rätsch 1990; Simonetti 1990).

In Angola, unspecified parts of S. guineense and S. huillense are used to poison fish (De Smet 1998). In Cape York, Australia, Syzygium spp. leaves were smoked as a substitute for tobacco [see **Nicotiana**] or pituri [see **Duboisia**]. In New South Wales, white settlers used fruits of S. australe to make wine [see *Methods of Ingestion*] (Low 1990). In Australia, some native Syzygium spp. are called 'lilly-pillys', and are known for their edible fruits.

Closely related, the fruits or flower buds of a Eugenia sp. called 'khraat' are consumed with types of ginger [see *Endnotes*], galangal [see **Kaempferia and Alpinia**] and other plants, in the first three stages of initiation by the Bimin-Kuskusmin of West Sepik, Papua New Guinea (Poole 1987).

S. aromaticum buds yield 15-19% essential oil, which is pale yellow with a sweet, spicy odour, becoming darker with age – it may contain 60-90% *eugenol*, 8-12% *eugenol* acetate, 6-10% caryophyllene, 0-2% isocaryophyllene, vanillin, furfurol, salicylic acid, methyl benzoate and other compounds; leaf oil [yield c.4-5%] is dark brown, and may consist of 72-90% *eugenol*, 0-10% *eugenol* acetate and 10-15% caryophyllene, and other constituents similar to the bud essential oil; stem oil is pale yellow with a strong spicy-woody odour, consisting of 87-96% *eugenol*, 3-3.5% *eugenol* acetate, 6-8% caryophyllene and traces of isoeugenol. Cloves have also yielded 12-13% tannins, 2-OH-4,6-dimethoxy-5-methyl-*acetophenone*, naphthalene, gallotannic acid, α-humulene and α-humulene epoxide I. Some of the sesquiterpenes in cloves may have anticancer activity (Battaglia 1995; Bruneton 1995; Erickson 1976; Ilyas 1978; Lawless 1995; Simonetti 1990; Zheng 1992).

Syzygium aromaticum is an evergreen tree to 9m or more tall. Leaves opposite, simple, elliptic-lanceolate to obovate-oblong, glossy, leathery, c.6-13.5(-15) x 2.5-5.25cm, base very acute, apex shortly obtuse-acuminate, pinnately veined, lateral nerves strongly approximated, thin, intramarginal nerve +- 1mm from margin, blade dotted with glands, strongly aromatic of cloves when crushed; petiole 1.25-2.5cm. Inflorescences terminal corymbose panicles, 3-20-flowered (usually few); calyx tube slightly produced beyond the ovary, 1-1.5cm high, subterete, subquadrangular, purple or yellowish-green with a red flush, lobes 4-5, ovate-triangular, +- 2mm long; petals 4-5, to 6.5mm across, separate or united into a cap, often falling early, yellow +- tinged with red; stamens many, white, emerging in a dense pompon after the corolla cap formed by the linked petals drops off, filaments 3-7mm; anther sacs opening by lateral valves. Ovary inferior, 2-4-celled, ovules many; style +- 3mm; stigma 2-lobed. Fruit a dark red berry, ellipsoid-obovoid, 2-2.5cm long, with 1-2 black seeds; seed-coat roughish, adhering loosely or closely to the pericarp; cotyledons appressed against each other with lobed inner surfaces.

Native to the Moluccas in the Indian Ocean; widely cultivated in warm, maritime tropical areas such as Indonesia, Sri Lanka, Java, Madagascar, Tanzania and Brazil (Backer & Bakhuizen van den Brink 1963; Bailey & Bailey 1976; Ilyas 1978; Simonetti 1990).

Prefers well-drained sandy loam, rich in humus, though will grow in a wide variety of soils. Prefers warm, humid climate, 20-30°C, average annual rainfall 150-200cm, alt. up to 900m. Propagate from fresh seed, within 7-10 days of fruit falling. Fruits are dehusked either by leaving in a heap for 2-3 days, or soaking in water for 24 hrs, softening the husk enough for it to be removed. Selected washed seeds [those that are light

green are best] should be planted in shaded, manured, raised beds 10-15cm apart and 2cm deep, covered with sand and soil; plant seeds laying flat with protruding radicle into the soil; water regularly. Most should germinate within 16-46 days. Unhusked fruits are sometimes planted instead, but germination rates are not as good. Transplant into pots or polythene bags with manured soil when 6 months old, still with shade and regular watering. When 1-2 years old, transplant to prepared beds in the ground during rainy season, 6-10m apart, with protection from wind, and some shading from surrounding trees. Fertilise with organic manure several times a year, raising the amount of fertiliser slightly each year until the 15th year. Trees bear flower buds [the 'cloves'] from 5-10 years of age, but only in good yield from the 15th year onwards; alternating wet and dry periods are thought to be beneficial in flower bud formation. The buds are harvested by hand when they are changing from green to crimson in colour. With the stalks separated, the buds are spread out for drying by any of a number of means; sun drying may take 4-7 days, and they lose 70-75% of their weight (Ilyas 1978). Some report that the buds are prepared by immersion in boiling water for a few seconds after picking, and then the stalk is removed and the buds are sun-dried. Clove essential oil is usually made by steam distillation of discards (Simonetti 1990).

TABERNAEMONTANA including ERVATAMIA

(Apocynaceae)

Tabernaemontana affinis *Müll. Arg.* **(Peschiera affinis** *(Müll. Arg.) Miers***)**

Tabernaemontana sananho *Ruiz et Pavón* **(T. poeppigii** *Müll. Arg.***; Bonafousia sananho** *(Ruiz et Pav.) Markgr.***; Merizadenia sananho** *(Ruiz et Pav.) Miers***)** – lobo sanango, yacu sanango, sanango de altura, tsicta, tsiikat, bai-su-su

Tabernaemontana sp. 'sananho' – uchu sanango

Tabernaemontana siphilitica *(L. f.) Leeuwenberg* **(T. cuyabensis** *Malme***; T. guianensis** *Miq.***; T. longifolia** *Benth.***; Echites siphilitica** *L. f.***)**

Tabernaemontana solanifolia *DC.* **(Peschiera affinis var. campestris** *Rizzini***; P. campestris** *(Rizzini) Rizzini***)**

Tabernaemontana sralensis *Pierre ex Pitard.*

Tabernaemontana stapfiana *Britten* **(T. johnstonii** *(Stapf.) Pichon***; Conopharyngia bequaerti** *De Wild.***; C. johnstonii** *Stapf.***; C. stapfiana** *(Britten) Stapf***;)**

Tabernaemontana tetrastachya *Kunth* **(T. longifolia** *Benth.***; Bonafousia tetrastachya** *(Kunth) Markgr.***; Malouetia tetrastachya** *(Kunth) Miers***)** – uchu sanango, saticu, bee'-e-ge

Tabernaemontana vitiensis *Seeman nom. nud.* **(T. orientalis** *Seeman***; Ervatamia obtusiuscula** *Markgraf***; E. orientalis** *Turrill***)**

Ervatamia lifuana *Boiteau* **(E. orientalis** *Guillaumin***)**

This large genus is notable for its species containing the psychotropic stimulants *ibogaine*, *voacangine* and related indole alkaloids. They have many medicinal uses, and are only occasionally reported to be used for their psychoactive properties. For greater clarity in this complex entry, each species discussed will be listed together with its alkaloidal content, in contrast to the trend in other entries. This should not be seen as a comprehensive coverage. Excellent reviews of the chemistry of the genus have been published by Danieli & Palmisano (1986) and Van Beek et al. (1984).

T. affinis leaves are toxic to cattle. Roots from Brazilian plants yielded *yohimbine* and serpentine (Van Beek et al. 1984); in other studies of Brazilian plants, root bark yielded 20-epi-heyneanine as the major alkaloid, with lesser amounts of *coronaridine*, *coronaridine* pseudoindoxyl, affinisine and olivacine (Matos et al. 1976); others found *coronaridine*, *vobasine*, *voacangine*, *voacristine*, *iboxygaine*, 19-OH-*iboxygaine*, affinisine, olivacine and epiheyneanine in bark and roots (Filho et al. 1987).

T. amblyocarpa from Cuba has yielded *ibogamine*, *akuammidine*, iso-*voacangine* and iso-*voacristine* from leaves; leaf and stem combined yielded *coronaridine*; and stem yielded *voacangine*, *voacristine*, vallesamine and (+)-tubotaiwine (Van Beek et al. 1984).

T. australis stems have yielded 0.054% *voacangine* and 0.016% *voacamine* (Gorman et al. 1960); in Paraguay, the latex is used to heal warts (Van Beek et al. 1984).

T. brachyantha from s. Nigeria and w. Cameroon is used as a febrifuge, in the form of crushed twigs mixed with **Ocimum** spp. Its bark has yielded *ibogaine*, *voacangine*, *coronaridine*, conopharyngine [analgesic, smooth muscle relaxant, hypotensive, bradycardiac, appears to be psycho-

tropic in animals] and voacangarine; voacorine, anhydrovobasindiol and normacusine B have also been found in the stem bark (Burkill 1985-1997; Carroll & Starmer 1967; Danieli & Palmisano 1986; Patel et al. 1967; Van Beek et al. 1984).

T. citrifolia latex is applied topically to remove warts in Central America (Usher 1974), and in the Antilles the bark is used as a bitter tonic, anthelmintic and febrifuge (Van Beek et al. 1984).The root has yielded 0.025% *ibogamine*, 0.006% *voacangine*, 0.006% *coronaridine* (Gorman et al. 1960) and *voacamine*; leaves have yielded apparicine, *coronaridine*, *voacangine* (Van Beek et al. 1984), voacangarine, pandoline, pandine, conoflorine, akuammicine, pleiocarpamine, sitsirikine, rhazinaline, vallesiamine, fluorocarpamine, tabersonine [see **Voacanga**], *ibogaine*, *iboxygaine* and *ibogamine*. *Voacristine*, 3-oxovoacristine, *akuammidine* and lochnericine have also been found in the plant, amongst other alkaloids (Abaul et al. 1989; Danieli & Palmisano 1986).

T. coffeoides leaves and bark are used in Madagascar to relieve fatigue, hunger and stomach cramps; a stem bark decoction is also given as a strengthening medicine to nursing mothers (Van Beek et al. 1984). The root has yielded *coronaridine*, *ibogamine*, *voacangine*, *vobasine*, dregamine, tabernaemontanine, methuenine, silicine, apparicine, tabernaelegantine A, 3,14-dihydroellipticine and other alkaloids; leaves have yielded *akuammidine*, methuenine, pericyclivine, polyneuridine, dregamine, hazuntine, hazuntinine, silicine, (+)-stemmadenine, tabernaemontanine, vallesamine, vincanidine, voacarpine, *vobasine*, voaphylline, lochnericine, tabersonine, (-)-heyneanine and other alkaloids; stem bark has yielded apparicine, reserpinine, dregamine, methuenine, normacusine B, tabernaemontanine, voacarpine, *vobasine*, silicine, tetraphyllicine, isovoacangine, 3,14-dihydroellipticine and other alkaloids (Danieli & Palmisano 1986; Van Beek et al. 1984).

T. contorta bark has yielded *ibogaine*, *voacangine*, *voacristine*, *coronaridine* and conopharyngine (Danieli & Palmisano 1986; Patel et al. 1967).

T. corymbosa is used in Malaysia to treat syphilitic and orchitis ulcerations, and in Thailand the bark and roots make an arrow poison (Van Beek et al. 1984; Zeches et al. 1995); root barks of other unidentified Tabernaemontana spp. are also used to make dart-poisons in Malaya (Bisset & Woods 1966). As T. yunnanensis, T. corymbosa is used in China to treat hypertension (Gui et al. 1988). Leaves have yielded 4.2% alkaloids, of which 1.5% was *yohimbine*, 45% β-*yohimbine*, 0.75% β-*yohimbine* pseudoindoxyl, 0.3% β-*yohimbine* oxindole, 2% modestanine and 1% vandrikine; stem bark yielded 2% alkaloids, of which 46% was β-*yohimbine*, 1% each of the above *yohimbine*-derivatives, less than 0.1% modestanine and 4.3% normacusine B (Zeches et al. 1995); roots have yielded *ibogaine*, *ibogamine*, *coronaridine*, *voacangine*, *voacangine* OH-indolenine, voachalotine, (+)-minovincinine and ervayunine (Gui et al. 1988).

T. crassa from w. Africa has many uses. The caustic sap is used as an arrow poison, sedative for insanity, disinfectant, haemostatic, anthelmintic, and as a dressing for sores and nose-drops for headache. One drop of the latex may cause blindness if brought into contact with the eyes. In Ivory Coast, the bark is given as an enema for constipation, kidney troubles and rheumatism; the leaf is rubbed into the body to strengthen and relieve fatigue. The Ebrié decoct the leaves as a tonic, given to "mentally retarded children and tired adults" (Burkill 1985-1997; Van Beek et al. 1984). Stem bark has yielded 0.268% crude alkaloids, including isovoacangine, conopharyngine, and an unidentified alkaloid; root bark yielded 0.763% crude alkaloids, including isovoacangine, conopharyngine, conodurine, conoduramine, and the same unidentified alkaloid (Renner et al. 1960). *Ibogaine* is the main bark alkaloid, with lesser amounts of conopharyngine (Van Beek et al. 1985), *voacristine*, (-)-heyneanine, *coronaridine*, akuammiline, anhydrovobasindiol, O-acetylpolyneuridine, 19-OH-conopharyngine and other alkaloids also found. Seeds have yielded tabersonine, *coronaridine* and *coronaridine* hydroxyindolenine. *Ibogamine* has been reported from unspecified parts, as well as perivine, pericyclivine, *vobasine* and gabunine (Carroll & Starmer 1967; Danieli & Palmisano 1986; Van Beek et al. 1984).

T. crassifolia from Madagascar yielded *ibogamine* and *tabernanthine* from stem bark (Van Beek et al. 1984).

T. dichotoma seeds are known in India to be a powerful deliriant 'narcotic' compared to **Datura**; they also have purgative properties. The fruit ['Eve's apple, 'forbidden fruit'] is variously said to be edible or a deadly poison. The leaf and bark are purgative, and the sap is laxative. The roots are sometimes chewed in Sri Lanka to relieve toothache (Chopra et al. 1965; Nadkarni 1976; Van Beek et al. 1984). The fruit has yielded *coronaridine*, tabersonine, perivine, *vobasine*, apparicine, vallesamine, dichomine and other alkaloids; seeds yielded *ibogamine*, *voacangine*, voaphylline, voaphylline hydroxyindolenine, *tabersonine*, *coronaridine* and stemmadenine; root bark has yielded *coronaridine*, 19R-heyneanine and *voacristine* hydroxyindolenine; stem bark yielded *ibogamine*, *voacamine*, *vobasine*, *coronaridine* and many other alkaloids; leaves yielded 0.19% alkaloids – apparicine, 19-epiiboxygaine, 19-epivoacristine, 12-MeO-voaphylline, *vobasine* and isomethuenine (Danieli & Palmisano 1986; Perera et al. 1983, 1985).

T. divaricata wood is used in incenses and perfumes. In India, the root bark is chewed to relieve toothache; it is reputed to be an aphrodisiac, brain tonic, antirheumatic and antiepileptic, amongst other properties. The plant is generally reputed to destroy poisons, give longevity, and promote conception and hair growth; it is often applied in oil, or clarified butter and water, with other ingredients. In Indonesia, the root is decocted for diarrhoea. In Pakistan, Yunani doctors use the flowers as an analgesic. In Burma, unspecified parts are used in preparing yeast cakes for the manufacture of rice beer [see 'chhang' in *Methods of Ingestion*]. In the Mentawei Islands, Indonesia, aerial parts are used as the main ingredient of an arrow poison (Nadkarni 1976; Usher 1974; Van Beek et al. 1984). In Malaysia, the flowers of the single-flowered variety are used in religious rites. The plant is much cultivated in s.e. Asia, and is used as a cancer remedy in Taiwan. Stems yielded 0.016% tabernaemontanine, 0.007% *voacamine*, 0.0035% descarbomethoxy-*voacamine*, 0.013% 19,20-dihydroervahanine A [a new alkaloid], 0.0029-0.006% *coronaridine*, 0.004% heyneanine, 0.022% *voacristine* and 0.001% dregamine; as well as the phenolic acids vanillic acid, gentisic acid, syringic acid, salicylic acid and 4-OH-benzoic acid. Stem extracts had analgesic, sedative and antiinflammatory effects. Flowers have yielded tabersonine, voaphylline, apparicine and hecubine (González, C.G. et al. 1982; Gorman et al. 1960; Henriques et al. 1996; Kam et al. 1993; Sharma & Cordell 1988). Leaves of the variety with a single whorl of petals [diploid] yielded [w/w] 0.00003% *coronaridine*, 0.015% *voacangine*, 0.000025% voaphylline and 0.0001% tabernaemontanine; leaves of the variety with a double whorl of petals [triploid] yielded [w/w] 0.0014% voaphylline and 0.000086% lochnericine (Raj et al. 1974). The plant has also yielded *ibogamine* and other alkaloids from the stem bark and root bark (Danieli & Palmisano 1986; Van Beek et al. 1984). One psychonaut found 40-50g of commercially-obtained root to "induce a 12 hour plus mellow walking dreaminess", with "a mild, pleasant sedation lingering afterward for a few days". However, he stressed that this may not be indicative of the potency of other T. divaricata specimens (Hoodoo pers. comm. 2002).

T. echinata leaves yielded 2.04% alkaloids, consisting of *voacangine*, *voacristine*, *vobasine*, *coronaridine*, pleiocarpamine, tubotaiwine, angustine and others; stem bark 1% alkaloids, of which 25% was 10-MeO-eglandine, as well as *ibogaine*, *ibogaine* 7-OH-indolenine, *voacamine*, *coronaridine*, pleiocarpamine and others; root bark 0.14% alkaloids, consisting of *ibogaine*, *voacamine*, voacamidine, *vobasine*, olivacine, N-dimethylvoacamine and decarbomethoxyvoacamine (Ghorbel et al. 1981).

T. eglandulosa root bark has yielded *coronaridine*, isovoacangine, perivine, *voacamine*, *vobasine* and other alkaloids; stem bark has yielded *voacangine*, *coronaridine*, conopharyngine, tacamine and other alkaloids (Van Beek et al. 1984); *ibogamine*, voaphylline, tacamonine, tubotaiwine, dichomine and norfluorocurarine have also been found in the plant. The root is abundant in alkaloids, the stem bark less so. Its sap is sometimes used to adulterate rubber in w. Africa (Burkill 1985-1997; Danieli & Palmisano 1986; Patel et al. 1967).

T. elegans seeds are used in S. Africa as an additive to chewing- or smoking-tobacco [see **Nicotiana**]; for this purpose, they are burnt and ground before being mixed with the tobacco. Root bark of specimens from Mozambique yielded conoduramine, dregamine, tabernaemontanine, tabernaelegantines A-D and tabernaelegantinines A-D (Van Beek et al. 1984).

T. eusepala stem bark has yielded 1.9% alkaloids; root bark 2.85%; and leaves 0.85%. These consisted of [as % of total alkaloids] *ibogaine* [15-50%], *ibogaine* hydroxyindolenine [4%], *vobasine* [2%], 19-epi-voacangarine [9%], apparicine [4%], 19,20-dihydrocondylocarpine [8.5%][may be identical to tubotaiwine or epi-20-tubotaiwine], (20S)-1,2-dehydropseudoaspidospermidine [11%], and the (20R)- and (20S)- isomers of 15,20-dihydro-cleavamine [17.5% and 4%, respectively] (Quirin et al. 1975).

T. eusepaloides from Madagascar yielded *ibogaine* from the root bark (Van Beek et al. 1984).

T. fuschiaefolia stem bark has yielded conopharyngine, *coronaridine*, affinisine, 16-epi-affinine, *voacangine*, 12-MeO-N-methylvoachalotine, voachalotine, *ibogaine* and/or *tabernanthine*, *voacamine*, voacamidine, N-demethylvoacamine, 16-decarbomethoxyvoacamine, *vobasine*, perivine and unidentified alkaloids, in varying concentrations (Lépine et al. 2002).

T. hainanensis roots and leaves are used in China to treat hypertension, stomach ache, dysentery, rheumatoid arthritis, hepatitis and snakebites. Roots have yielded 0.3% alkaloids, consisting of monomeric indoles [mostly *coronaridine*, with lesser amounts of *vobasine*, *ibogamine*, heyneanine, perivine, geissoschizol, *coronaridine* OH-indolenine, 3-oxo-*coronaridine*, 3-(β-hydroxyethyl)-*coronaridine*, 10-OH-heyneanine, and 10-OH-geissoschizol] and dimeric indoles [ervahanines A-C] (Feng et al. 1982); a later study also found the *voacamine*-type alkaloids ervahaimine A, ervahaimine B, ervahainamidine A and ervahainamidine B (Feng et al. 1989).

T. heyneana fruit flesh has yielded *coronaridine*, heyneanine and an unidentified alkaloid (Saradamma et al. 1971); *ibogamine* has been found in the root; stems have yielded alkaloids such as *voacangine*, *voacristine*, *coronaridine*, (+)-tubotaiwine and apparicine (Van Beek et al. 1984).

T. humblotii stem bark has yielded 1.3-2.1% alkaloids [20% *ibo-*

gaine, 6% *voacangine*, 12% voacangarine, and <1% each of *iboxygaine*, iboluteine and descarbomethoxy-*voacamine*]; root bark 2.7-3.1% [30% *ibogaine*, 8% *voacangine*, <1% each of iboluteine, descarbomethoxy-*voacamine*, akuammicine, *akuammidine* and dihydrocondylocarpine]; and leaves 0.9-1.6% [10-29% *ibogaine*, 5% *ibogaline*, 8% epi-19-*iboxygaine*, 5% epi-19-iboxygaline, 0-17% akuammicine, 13% voacangarine, 3% epi-16-dehydro-14,15-*vincamine*, <1% apparicine] (Lévy et al. 1975; Panas et al. 1974). *Voacristine* and tubotaiwine have also been found (Danieli & Palmisano 1986).

T. lundii leaves, stems and bark yielded 0.85% crude alkaloids; unfortunately, due to the way in which the analysis is reported it is difficult to calculate real yields. Alkaloids found were *ibogaine*, *iboxygaine*, *iboxygaine* OH-indolenine, *voacangine*, *voacristine*, 20-epivoacristine, *voacristine* pseudoindoxyl, *vobasine* and *coronaridine* (Hwang et al. 1969).

T. muricata is employed in the lower Rio Vaupes [Colombia], where natives sometimes use the sun-dried leaves and flowers to add stimulant activity to their fermented 'chicha' brew [made in this case from Manihot spp.; see *Methods of Ingestion*] (Schultes & Raffauf 1990). Its chemistry appears to be still unknown, though it has given positive results in alkaloid screening (Van Beek et al. 1984).

T. olivacea stems have yielded 0.489% crude alkaloids, in which was found 3.6% *coronaridine*, 0.2% *coronaridine*-OH-indolenine, 0.2% *coronaridine*-pseudoindoxyl, 2% *voacristine*, 1.1% *voacangine*, 0.15% *voacangine*-OH-indolenine, 0.1% *voacangine*-pseudoindoxyl, 0.2% *ibogaine*, 0.8% *ibogamine*, 0.2% *akuammidine*, 0.3% heyneanine and condylocarpine N-oxide (Achenbach & Raffelsberger 1980b).

T. orientalis is used by some indigenous inhabitants of Queensland [Australia] to disinfect ulcers and sores, and promote the healing process; the milky latex from the stem or fruit is used for this purpose. Early white settlers sometimes used the bark as a bitters (Cribb & Cribb 1981; Lassak & McCarthy 1990). In Fiji, the leaves are decocted to treat stomach ache, and the bark for headache; in Tonga, the grated root may be infused and used as a mouthwash to relieve toothache. In Samoa, the leaves have been used as an ingredient of arrow poisons. The plant has been suspected of killing cattle and horses (Van Beek et al. 1984). An extract of T. orientalis acted as a pleasant stimulant in small doses [quantity unspecified], though larger doses caused an unpleasant psychedelic experience accompanied by temporary blindness in one psychonaut (Torsten pers. comm.). T. orientalis bark [harv. Jun.-Jul.] has yielded 1.3-2% alkaloids, consisting of the indoles tabernaemontanine, ervatamine, dregamine, *vobasine*, *voacamine*, *voacristine*, 19-dehydroervatamine, de-MeO-carbonyl-voacamine, 16-de-MeO-carbonyldihydrovoacamine, 16-de-MeO-carbonyl-20'-epidihydrovoacamine and 20-epiervatamine; leaves [harv. Jul] yielded 0.13% alkaloids, consisting of *ibogaine*, apparicine, *iboxygaine*, ervatamine and 19-dehydroervatamine (Knox & Slobbe 1975). Another leaf sample [harv. time unspecified] yielded 0.84% alkaloids, of similar constituency (CSIRO 1990); leaves from New Guinea plants yielded 0.4-0.5% alkaloids, consisting of *voacangine*, conopharyngine, pandine and pandoline; no ervatamine- or *vobasine*-type alkaloids were found (Allorge et al. 1980). Other samples of unspecified harvest time yielded 0.53% alkaloids from leaf and fruit, and 0.61% alkaloids from the bark (Hartley et al. 1973). Plants from Mossman [Qld, Australia] harvested in August tested strongly positive for alkaloids in mature fruits, but weaker in leaves (Webb 1949). 2000mg/kg [oral] of the leaf alkaloids were lethal in mice; stem bark and leaf extracts are also active against Lewis lung carcinoma (CSIRO 1990). As Ervatamia daemeliana, specimens growing in Queensland [Australia] yielded 0.4-0.5% alkaloids from the leaves, including conopharyngine, *voacangine*, *iboxygaine* and *akuammidine* (Allorge et al. 1980). As Ervatamia pubescens, plants from Papua New Guinea yielded 0.48% alkaloids from the leaf (Hartley et al. 1973).

T. pachysiphon is used in w. Africa to trap birds, by means of its latex; this may also be applied to ulcers, and for mending broken pots. A decoction of the root bark treats insanity or mania in Nigeria and Ghana; it also acts as a hypnotic, and treats headache, flatulence, constipation and stomach ache. Leaves have yielded conopharyngine as the major alkaloid. Bark and seeds have yielded *voacangine*, conopharyngine and other alkaloids; root has yielded *vobasine*, perivine, pericyclivine, gabunine, *coronaridine*, conodurine, conoduramine and other alkaloids. The plant has also yielded *ibogaline*, *voacamine* and many others (Burkill 1985-1997; Carroll & Starmer 1967; Danieli & Palmisano 1986; Patel et al. 1967; Van Beek et al. 1984; Watt 1967).

T. pandacaqui is used in Thai folk medicine as a sedative analgesic, and the leaves for bleaching in the Philippines (Ott 1993; Van Beek et al. 1984). In Australia, as Ervatamia angustisepala, the root bark has reportedly been used to treat tropical fevers (Cribb & Cribb 1981; Lassak & McCarthy 1990). Bark from Jamaican plants yielded *ibogamine*, *iboxygaine*, *coronaridine*, *tabernanthine*, isovoacangine and *voacristine*. Leaves from Philippines plants yielded ervafoline, ervafolidine, isoervafolidine, pericyclivine, (+)-20-epi-lochneridine and tabernaemontanine (Van Beek et al. 1984). Stems from a Philippines collection [Feb.] yielded only *voacangine*, *voacristine*, voaluteine, tabernaemontanine, ervatamine and pandine, whilst leaves yielded *voacangine*, *voacristine*, pandine, akuammicine, vallesamine and vallesamine 17-O-acetate (Abe et al. 1993). Roots from Borneo [harv. Nov.] yielded 0.052% *voacangine* (Okuyama et al. 1992). As E. angustisepala, bark of Australian plants yielded 0.46% alkaloids, the identity of which was not investigated. The alkaloid extract caused decreased activity, ledge unsteadiness, dyspnoea, piloerection and an anticonvulsive effect in mice at 200mg/kg [oral]; hypotensive in anaesthetized cats at 39-79mg/kg [i.v.]; active against cell culture tumours (CSIRO 1990). Bark, leaf and stem of Australian plants all tested strongly positive for alkaloids (Webb 1949).

T. pauciflora is used for its analgesic effects to treat toothache in Sabah State, Borneo. Roots [harv. Oct.] yielded [w/w] 0.033% *coronaridine*, 0.01% 3-(2-oxopropyl)-*coronaridine*, and traces of 5R- and 5S-(2-oxopropyl)-*coronaridine*, 3,3'-(oxopropyl)-dicoronaridine, and 3-(2-oxopropyl)-*voacangine* (Okuyama et al. 1992).

T. penduliflora bark has yielded *voacangine*, *coronaridine* and conopharyngine, from Nigerian plants (Patel et al. 1967; Van Beek et al. 1984).

T. psorocarpa stem bark yielded 0.05% alkaloids – mostly 16-epiisositsirikine, as well as *voacangine*, 12-MeO-14,15-dehydrovincamine, *coronaridine*, tetrahydroalstonine, vallesiachotamine and isovallesiachotamine (Van Beek et al. 1983).

T. psychotriifolia roots yielded 0.99-1.17% alkaloids, including 0.026% *coronaridine*, 0.021% *voacangine*, 0.01% *voacamine* and 0.034% olivacine (Gorman et al. 1960); specimens from Guyana also contained *ibogaine* and other alkaloids in the root bark and stem bark (Van Beek et al. 1984).

T. quadrangularis roots yielded 1% crude alkaloids, in which was found 10.7% *coronaridine*, 0.7% *coronaridine*-lactam, 0.5% *coronaridine*-OH-indolenine, 0.1% *coronaridine*-pseudoindoxyl, 4% *voacangine*, 0.03% *voacangine*-lactam, 0.1% *voacangine*-OH-indolenine, 0.03% *ibogaine*, 2.3% *ibogamine*, 0.15% *ibogamine*-pseudoindoxyl, 0.07% (20R)-20-OH-*ibogamine*-pseudoindoxyl, 1.7% (20R)-20-OH-*ibogamine*, 0.3% (20S)-heyneanine, and 0.07% (20R)-epiheyneanine (Achenbach & Raffelsberger 1980a). The identity of the plants analysed is uncertain, as the species name does not seem to appear in any botanical literature (pers. obs.; Van Beek et al. 1984).

T. retusa root bark has yielded 0.91% alkaloids; trunk bark 0.46%; and leaves 0.37%, in one analysis of Madagascan plants. Trunk bark alkaloids consisted of 18% heyneanine, <1% *voacangine* and <1% *coronaridine*; leaf alkaloids consisted of 18% *voacangine*, 7% oxo-3-*voacangine*, 3% *coronaridine*, 3% heyneanine and 1.5% *voacristine* (Picot et al. 1973). In another analysis of Madagascan plants, root bark yielded *ibogamine*, heyneanine, *coronaridine* and *coronaridine* hydroxyindolenine; seeds yielded tabersonine, *voacangine*, voaphylline, *coronaridine* and pachysiphine (Van Beek et al. 1984).

T. rimulosa is considered a panacea in w. Amazonia, and is used to treat fever and rheumatism, as well as being emetic, diuretic and calmative. Venezuelan settlers in San Filipe, Rio Negro, use a decoction of several leaves in milk to treat insomnia (Schultes & Raffauf 1990).

T. sananho is used by the Quijos Quecha as a psychotrope, taken along with the sap of **Osteophloeum** platyspermum and **Brugmansia** spp. (Ott 1994). Made into a tea alone, the bark causes initial unpleasant side-effects, but later leads to greater awareness of one's surroundings and increased sensory sensitivity, and is thus used as a hunting aid. The Shushifindi Secoya put the fruit juice in their dog's noses to help them 'smell further'. The bark juice treats toothache, and the bark has also been used as a contraceptive and antirheumatic; the pulp may be gargled for sore throats and colds; and the dilute latex cures eye wounds (Ott 1993; Schultes & Raffauf 1990; Van Beek et al. 1984). One psychonaut found 8g of commercially-obtained roots to be similar in quality and strength to 40-50g of T. divaricata root [see above], though more stimulating; higher doses had sedative rather than stimulant effects (Hoodoo pers. comm. 2002). Bark from Peruvian plants has yielded *ibogamine*, *voacangine*, *coronaridine*, 3-OH-*coronaridine* and heyneanine (Van Beek et al. 1984).

T. sp. 'sananho' may or may not be the same as the above species. It is used as an ayahuasca additive [see **Banisteriopsis**] and dart poison ingredient. It is said that "only the strongest vegetalistas can prepare it", being very dangerous, even deadly. It is considered a powerful plant teacher, and is also taken by itself under a 1 month diet, to learn from the plant. It has yielded *coronaridine*, other bis-indole alkaloids, and triterpenes (Bear & Vasquez 2000; Luna 1984; Luna & Amaringo 1991; McKenna et al. 1995; Ott 1993; Schultes 1972).

T. siphilitica latex is dropped into the eyes by the Makuna of Colombia to stay awake. Leaves from Guyanan plants yielded *coronaridine*, vincadifformine, *voacangine*, isovoacangine, tetrahydroalstonine, apparicine, pleiocarpamine, geissoschizine, tetrastachyne, tetrastachynine, (+)-tubotaiwine and other alkaloids (Van Beek et al. 1984).

T. solanifolia leaves yielded isovoacangine and isovoacristine; roots yielded 0.25% 12-MeO-N-methylvoachalotine [major constituent], *coronaridine*, *voacangine*, *voacangine*-OH-indolenine, *voacamine*, heyneanine and voachalotine; bark yielded *voacamine*, heyneanine, *vobasine*, voachalotine and 12-MeO-N-methylvoachalotine (Gower et al. 1986).

T. sphaerocarpa fruit is used to relieve toothache in e. Malaysia; in Indonesia, the root is added to some arrow poisons, and the plant as a whole is considered 'very poisonous' (Van Beek et al. 1984). Specimens

from India yielded dregamine and tabernaemontanine from leaves, stems and bark; young leaves contained the lowest levels of alkaloids, and root bark contained the highest. Maximum yields were obtained in Nov., decreasing until Apr. (Biswas 1973).

T. sralensis root is chewed with betel nut [see **Areca**] in Kampuchea; one piece is added to the quid (Van Beek et al. 1984).

T. stapfiana bark and stems from Kenyan plants yielded *ibogamine*, isovoacangine, conodurine, conoduramine, 19',20'-epoxyconoduramine, gabunine, gabunamine, perivine and pericyclivine; stem bark yielded tabernamine. Root bark of plants from Zaire yielded (+)-tubotaiwine and tubotaiwine N-oxide (Van Beek et al. 1984).

T. tetrastachya latex is put in the eyes by the Makuna to prevent sleep; the root and leaves have also been applied externally or infused for rheumatism in other areas of the Amazon (Schultes & Raffauf 1990). Chemical studies are lacking.

T. vitiensis from New Hebrides yielded 0.4-0.5% alkaloids from the leaves, including *coronaridine*, iso-*voacangine*, tabernaemontanine, and dregamine, with smaller amounts of *vobasine* and epi-pandoline (Allorge et al. 1980).

Ervatamia lifuana from New Caledonia yielded 0.35% alkaloids from the leaves, of which 2% was *voacangine*, 1% *coronaridine*, 10% conopharyngine, 4% pandoline, 5% epipandoline, 10% pandine, 0.3% epiervatamine, 0.05% ervatamine, 15% dregamine, 15% tabernaemontanine and 1% *vobasine* (Allorge et al. 1980; Bruneton et al. 1980). This species is considered by some to be synonymous with T. orientalis (Van Beek et al. 1984).

Tabernaemontana dichotoma is a small, dichotomously-branched tree with milky latex; young parts glabrous, covered with a shiny resinous coat. Leaves opposite, 10.1-17.8cm long, lanceolate-oblong, tapering to base, suddenly and shortly acuminate, obtuse, stiff and coriaceous, dark green above; main nerves 10-22 pairs at right-angles to the midrib and meeting in loops, impressed above; petiole 1.3-3.2cm, stout; axillary stipules usually distinct; axillary glands small, usually numerous. Flowers white, in few-flowered and terminal and leaf-opposed cymes; peduncles 5-15cm long, stout; pedicels stout; calyx small, 5-lobed, glandular inside; corolla salver-shaped, 3.8-7.6cm across, tube cylindric, 2-2.54cm long, fleshy, slightly dilated towards the naked mouth, lobes overlapping usually to the left, falcately twisted, often crisped at margin; stamens included and enclosed in corolla tube; filaments very short; anthers free from stigma; disc 0. Ovary of 2 free, sometimes slightly coherent carpels; ovules numerous, many-seriate; style usually long, filiform; stigma clavate or oblong with a bifid apiculus; ripe carpels broadly ovoid, blunt, smooth, orange-yellow; follicles 2, coriaceous when mature, obliquely ovoid to lanceolate, usually curved and beaked. Seeds surrounded by a coat of crimson pulp.

India, at low altitudes; occasionally cultivated as an ornamental (Chopra et al. 1965).

Tabernaemontana orientalis is a small shrub 1-4.6m tall, with milky sap in stems; branchlets glabrous; young shoots smooth. Leaves opposite, smooth, large, glabrous, elongated-oval, tapering to base, blade 8-22.5 x 3.5-7cm, light green, elongated acuminate at apex, not punctate below; distinct venation, lateral nerves diminishing until inconspicuous near margin, sometimes slightly archingly joined, nervation irregularly transverse; petioles to 1cm long, base with or without axillary glands. Inflorescence paniculate, terminal or in upper leaf axils, partial inflorescences dichasial; flowers white, tubular with twisted petals, sweet-scented, 1-2.5 x c.1-1.5cm, in few-flowered groups; calyx deeply 5-lobed, lobes acute; corolla with long tube, often slightly twisted below stamens, lobes glabrous, clockwise, rarely anticlockwise covered in bud; stamens inserted above the middle of the tube; anthers mucronulate at apex; disc indistinctly developed. Ovary apocarpous, the 2 carpels free or connate at base only, at apex connate by style, with 2-many ovules in 2-6 series; style filiform or clavate towards apex; stigma conoid or ellipsoid in basal part, apical part subulate. Fruit pairs of smooth dehiscent drupes with thin pericarps, curved, 3-sided banana-shaped segments, each 1.5-2 x 0.7-0.8cm, orange when ripe, containing several seeds. Fl. (Sep.-)Oct.-May; fr. Feb.-Aug. (Brock 1988; Van Royen et al. 1971).

In vine thickets; Melanesia, New Guinea, Australia [WA (Kimberley region), NT (monsoonal region), Qld (e. coast)] (Forster & Williams 1996).

T. divaricata should be grown in a high-light situation; prefers 15-29°C, and 25% or more relative humidity. Propagate from seed, or from tip-cuttings 10-15cm long, with 3 or more leaves. Keep soil moist on surface; if leaf loss occurs, water more frequently. Pinch back tips to stimulate branching. May benefit from feeding every 2 months, from spring to autumn. Sometimes suffers from infestations of spider mites under the leaves (pers. comms.).

TABERNANTHE

(Apocynaceae)

Tabernanthe iboga *Baill.* **(T. bocca** *Stapf.***; T. mannii** *Stapf.***; T. pubescens** *Pichon***; T. subsessilis** *Stapf.***; T. tenuiflora** *Stapf.***)** – iboga, eboga, eboka, boga, libuga, bocca, lebogo, lebuga, dibuga, diboga, dibuyi, dibugi, mbasoka, kuta mbasoke, mebange, moabi, gifuma, nyoke [ñoke], dinyoke, oabe, minkolongo, mungondu, sese

The root-bark shavings from the iboga shrub [T. iboga] are used in western central Africa in small quantities as a CNS-stimulant and aphrodisiac. It helps warriors and hunters stay awake in long night-watches or hunts, and has been shown to increase endurance and stamina. However, its primary importance is as an initiatory entheogen, as utilised in Gabon by adherents of Bwiti, a native spirituality based on direct contact with the 'ancestors' [the 'Bwiti']. Bwiti has spread to other surrounding areas due to the genuine experience that it offers [despite Christian missionary attempts to stamp it out]. Bwiti is thought to have been introduced to the Fang by the Mitsogho [Metsogo], along with the custom of eating iboga roots. Previous to this, the Fang ate the leaves of the iboga shrub for shamanic 'dreaming'. Iboga root is now used mainly by peoples of the Fang and Mitsogho in elaborate initiation rituals, where a fully active dose of the plant is consumed for what will probably be the only time in one's life. For regular use, however, small quantities of the root bark are chewed for all-night drumming and dancing ceremonies. Sometimes, it is taken by shamans or others for divination on a pressing issue. The plant used is T. iboga, but sometimes varieties are used which were once recognised as separate species [such as T. mannii, T. pubescens and T. subsessilis, the former said to be 8-10 times stronger than 'typical' T. iboga]. Sometimes **Cannabis** is smoked as well, or its resin eaten. Sometimes **Alchornea** floribunda is taken with iboga in large amounts, and **Elaeophorbia** drupifera is also used when the iboga is slow to take effect (Fernandez 1982; Goutarel et al. 1997; Khuong-Huu et al. 1976; Pope 1969; Samorini 1993, 1995a, 1997a, pers. comm.; Schultes 1969c; Schultes & Hofmann 1980; Tyler 1966). The finer details of iboga ceremonies differ from group to group, but below we will look at one example.

Sex and food are abstained from the day before the iboga ceremony. Beginning at around 9am, iboga root bark is given orally in a powdered form, from a basket [usually about 20cm diameter] placed on a wildcat skin. It is eaten with the mouth, not the hands. Occasionally, an infusion is made, though this is less effective in extracting the alkaloids [which are not very water-soluble]. The initiate is given a 'mother' and 'father' of iboga, who oversee the consumption of the root and the successful journey of the initiate. Around 16 teaspoonfuls may have been consumed by midday, when an antelope horn is blown to "alert the ancestors that a descendant is coming among them." By 3pm, and another 16 tsp later, the initiate is led to a nearby stream, followed by several other people with important roles in the ceremony. Stripped to the waist, the initiate stands in the water and confesses past sins. Back on land, the aromatic leaves and flowers of Costus lucanusianus ['myan', 'okosakosa'] and leaves of **Piper** umbellatum ['abomenzan'; see **Piper 1**] are used to purify the initiate. 'Myan' is chewed and spat out by the father, who rubs it on the initiate before washing with stream water, to 'open the eyes'. 'Abomenzan' is then rubbed on by the mother, to win the sympathy of the spirits. Next, now naked, the initiate is rubbed down with the powdered bark of 12 trees [which are all used medicinally]. These are Bridelia grandis ['asas'], Distmananthus benthamianus ['eyen'], Enantia chlorantha ['mfol'], Guibourtia tessmannii ['ovung'], Kapaca guineensis ['asam'], Mimusops djave ['azap'], Musanga cecropioides ['aseng'; see *Endnotes*], **Ocimum** americanum ['adzam ntoma', 'elegalenga'], Polyalthia suaveolens ['otunga'], Psilanthemus manii ['azem'], Pterocarpus soyauxii ['mbel'] and Pycnanthus angolensis ['eteng']. The initiate then dons a white initiation smock, and after the other participants perform a symbolic reenactment of birth, s/he is hit over the head with large flowers from a 'parasol tree' ['zoseng aseng'] to symbolise 'cracking open the head' so that the soul may escape. Finally at the stream, the director of the ceremony lights a piece of pitch on a manioc leaf [the 'soul boat'] and drifts it downstream, between the initiate's legs, off to sea.

Back on land again, another 11 tsp are eaten and the initiate is helped back to the forest chapel, circling it, and coming to rest in front of it, where a sapling is planted that was pulled up the night before to determine if the ceremony should go ahead [its ease in being uprooted being a good sign]. All present help in planting the tree, which is the ladder by which the initiate climbs to the ancestors. At around 9pm, the initiate is taken to a chamber where more iboga is eaten for another hour or so, and the visionary phase of the experience begins fully. Administration of the drug stops when pin pricks in the spine fail to bring a response. It is said that no one will enter the full experience with less than 30tsp, and often as many as 60 may be given. This may translate to 1-3 baskets, or 200-1,000g, over an 8-24 hour period. Such high doses are only used once or twice in a lifetime to evoke full contact with the ancestors, to 'break open

the head', as it is often referred to. Some groups take it more regularly in smaller [non-visionary] amounts as part of their religious ceremonies, as mentioned above. For such use, 2-3 tsp [for women] or 3-5 tsp [for men] are taken early in the ceremony, with several more grams eaten halfway through after midnight, adding up to 4-20g of iboga. Such doses only elicit calm CNS-stimulation, a 'lightening' of the body and mild dissociation, as well as giving endurance for night-long dances. [However, some people have reported full-strength experiences from as little as 8g of root bark (Hoodoo pers. comm.).] It is not unknown for the seeds to sometimes be chewed, with a dose constituting 25-30 seeds.

The fully-active dose of iboga elicits a complex effect, with several distinct phases. Nausea and vomiting frequently occur earlier on, but amongst some groups it is not particularly desired, unless the initiate is in need of purging, as it means less of the iboga will be absorbed, and that the initiate may not be able to keep down the full dose. Others regard vomiting as essential to prevent death of the initiate, and the vomit is inspected carefully for signs of blood, which if found, will halt the ceremony. Initial effects are felt after about 20 minutes from beginning consumption, with agitation, loss of motor coordination, drowsiness, tremors, mood shifts, partial anaesthesia, alterations in blood pressure, and some degree of respiratory depression. After about 10 hours, vague coloured line hallucinations appear as though projected onto space; these commonly take the form of archetypal imagery. Objects are seen to shimmer with energy. These effects later give way to a lucid dream-like state, where the initiate is led through relevant events from their life and taken to a point where they may 'see' the course they must take. This period may last 5-10 hours, after which a relatively 'normal' consciousness returns, as does bodily sensation. At this stage, flashes of light are commonly seen around oneself. Energy levels are high during this period. The visionary phase is experienced much sooner when *ibogaine*, the major active iboga alkaloid, is taken as a single or dual dose. Over the next 20 hours or so, these events are re-integrated from a higher view-point during a phase of introspection. Residual stimulation may keep the person awake for many more hours, but only a few hours sleep is needed afterwards before the initiate can awaken feeling as good as new. In the last stages of the ceremony, it is considered important to relate to the group the visions and teachings that were received.

Sometimes deaths occur, usually with particularly high doses [above 1,000g] in frail or young people. Sometimes the dose reaches a toxic level [up to 6 or more times the fully-active dose of *ibogaine* (which is about 1g)]. Sometimes it is believed that in the visionary stage a person can be offered the chance to enter death and not return – if the initiate takes this path, then real physical death may be likely. Often, the ancestor-spirits are contacted beforehand by the elders to ask whether the ceremony should be performed. Some give a small dose of iboga the day before to test for any possible adverse reaction. The mother and father also monitor the physical and psychic state of the initiate to halt proceedings if any potential dangers or adverse physical reactions should arise. People with cardiac difficulties or high-blood pressure should probably not use iboga (De Rienzo et al. 1997; Fernandez 1982; Goutarel et al. 1997; Pope 1969; Samorini 1993, 1995a, 1997a, pers. comm. 1999; Schultes 1969c; Schultes & Hofmann 1980, 1992).

Iboga and *ibogaine* have been successfully used to interrupt drug addictions, notably those associated with opiates, *amphetamine*s, *cocaine*, *nicotine* and alcohol. This appears to arise from a complex biochemical reaction with the iboga alkaloids in areas of the brain directly related to addictive/compulsive behaviour – in a sense remodelling neurochemistry so that withdrawal symptoms or cravings do not persist after the experience, remaining effective in most subjects for up to 6 months. Reformed addicts after iboga usually adopt a more positive and constructive approach towards their own lives, revitalised and inspired by the revelations and trials of the iboga experience [which involves "release of repressed memories, intellectual re-evaluation of these memories, and integration of new insights"] (Popik et al. 1995).

Up to the time of printing, *ibogaine* has still not gained widespread official use as an addiction treatment, due mainly to resistance from a variety of US Government department officials who have the power to legalise the treatment and allow it to proceed. Many in this standing have financial interests in synthetic opiate-substitutes [which merely prolong withdrawal, have a low success rate, and substitute one addictive drug for another], currently widely used to 'treat' heroin addicts. Studies have been sponsored which found some degree of *ibogaine* neurotoxicity in animals at high doses [disputed in part by some other studies], and such results have been used as the main public evidence for the suppression of *ibogaine*, even though they may have little relevance to the real-life therapeutic use of iboga or *ibogaine* by humans in addiction treatment. Also, because *ibogaine*, being an indole alkaloid psychedelic [although qualitatively and quantitatively very different from the classic indole psychedelics], was blanket-banned with all of the other psychedelics, many have found it hard to see the chemical in an acceptable light (De Rienzo et al. 1997). Whatever the case, *ibogaine* is clearly not a recreational substance with abuse potential – the experience that it offers, though of high personal and spiritual value, is a long and arduous one, that at times may be quite unpleasant [although a somewhat detached, non-emotive mental state is exhibited – the experience may be neither delightful or horrifying – it just IS...] (pers. comms.). However, small [sub-psychedelic] doses of iboga root can act as a pleasantly euphoric stimulant. Some people still experience nausea at these low doses (theobromus pers. comm.). See the *Chemical Index* entries under *ibogaine* and related chemicals for more information.

T. iboga root bark has yielded 5-6% alkaloids [1-2.6% in whole root] – mostly *ibogaine* [c.1% of root bark, may be up to 80% of total alkaloids], as well as *ibogaline* [c.15% of total alkaloids], *ibogamine* [c.5% of total alkaloids], *tabernanthine* (Bruneton 1995; Delourme-Houdé 1947; Dybowski & Landrin 1901; Jenks 2002), *ibogaine*-OH-indolenine, *ibogamine*-OH-indolenine, iboluteine, desmethoxyiboluteine, *iboxygaine*, iboxyphylline, ibophyllidine, *voacangine*, *coronaridine*, eglandine, gabonine, iboquine, kimvuline and kisantine (Buckingham et al. ed. 1994; Dickel et al. 1958). Root wood, stem bark and leaves did not contain appreciable levels of *ibogaine* (Jenks 2002). Leaves of T. iboga var. 'sese' [see below] yielded 0.44% total alkaloids, including 0.0074% *ibogamine*, 0.013% a mixture of ibophyllidine and *ibogamine*, and traces of iboxyphylline; leaves of T. iboga var. 'minkolongo' [see below] yielded 0.32% alkaloids, including 0.015% a mixture of *ibogamine* and ibophyllidine, and 0.002% iboxyphylline (Khuong-Huu et al. 1976). The dried crude alkaloid extract was found to be stable "even after months of exposure to indirect sunlight and air" (Jenks 2002). See *Producing Plant Drugs* for discussion of the simple alkaloid-extraction procedure used by Jenks.

As T. pubescens, the root bark yielded 5.6% alkaloids – 2.6% *ibogaine*, 0.29% *voacangine*, 0.11% *voacangine*-OH-indolenine, 0.057% *voacristine* and 0.059% 3,6-oxido-*ibogaine*. Trunk bark yielded 2.1% alkaloids – 0.75% *ibogaine*, 0.21% *iboxygaine*, 0.21% 3,6-oxido-*iboxygaine*, 0.026% *ibogamine* and 0.02% *ibogaline*. Leaves yielded 0.8% alkaloids – 0.28% voaphylline, 0.04% voaphylline-OH-indolenine, 0.007% tetrahydroalstonine, 0.006% 11-OH-tabersonine, 10-OH-*coronaridine* and 10-OH-heyneanine. Fruits yielded 0.8% alkaloids, mostly *coronaridine* (Mulamba et al. 1981). When this major fruit/seed alkaloid was still uncharacterised, animal experiments showed it to potentiate the hypertensive activity of *epinephrine* (Delourme-Houdé 1947).

As T. subsessilis var. 'mebange' [see below], leaves have yielded 0.4% alkaloids, including 0.016% ibophyllidine, 0.0084% iboxyphylline and 0.0014% *ibogamine* (Khuong-Huu et al. 1976).

Tabernanthe iboga is an arborescent shrub to about 2m high; sometimes a small tree to 3m or more, bare to the top of the slender trunk of 150-180cm, then patently branched; branches and branchlets dichotomous, compressed at the nodes. Root robust, much branched; central bulbous mass 2-10cm thick, branching out 50-80cm; brown when fresh, grey when dried. Leaves opposite, petiolate, petioles 2-3mm long; elliptic-ovate or obovate-lanceolate, acuminate, base acute or long-cuneate, mostly 7.5-13 x 2.5-4.5cm, thinly coriaceous or membranous, a little fleshy, dark green, soft and rather glossy above, pale yellowish-green and rather shining beneath; nerves 9-11, oblique, arcuate; stipules interpetiolar, inside with dense rows of whitish cilia. Inflorescence loosely umbelliform or subcorymbose, from few to c.12-flowered, nutant, shorter than leaves; peduncle 1-4cm; pedicels about 8mm; flowers yellow or white, sometimes with pink spots; calyx 5-cleft, 1-1.5cm long, the lobes keeled, imbricate, carolline-yellowish, closely clasping the corolla-base; sepals broadly ovate or subtriangular, ciliolate, the inner with 1-2 basal glands within; corolla somewhat salver-shaped, sulphur-coloured, tube dilated below, about 5mm long, fleshy, gradually constricted towards throat, limb 5-cleft, segments rotundate, 2.5mm long, patented during flowering, soon revolute, contorted dextrorsely (as seen from above), unequal-sided, the outer side undulate; stamens inserted at the dilation of the corolla tube, filaments scarcely any; anthers 2mm long, subsessile, sagittate, shortly aristate at apex, surrounding stigma pyramidally. Ovary ovoid, entire, obsoletely bisulcate, unilocular; placenta central, multi-ovulate; style 2mm long, firm, cylindrical, bearing ovoid-acuminate stigma at apex, on a broad membranous disc. Ripe fruit ellipsoid, lemon-shaped and coloured, about 50 x 2-20mm, apex pointed or slightly curved, with a smooth, crustaceous pericarp, sometimes crowned with the persistent base of the style – contains a large amount of stinky latex; mesocarp white, pulpy; bearing 20-30 seeds. Seeds brown, globose or somewhat ellipsoidal, 3-6mm long, with a corky, lamellate-rugose testa. Fl. Nov.-Dec., fr. Dec.-Apr.

In small woods or damp forests, occupying deepest cracks of the rocks of the praesidium. Often cultivated. Gabon, s.e. Congo (Hiern 1898; Pope 1969; Schultes & Hofmann 1980).

The typical T. iboga is a shrub form of the species, with round fruit; the variety earlier known as T. mannii is a tree form, with elongated fruit (Samorini pers. comm.). However, Khuong-Huu et al. (1976) claimed that T. subsessilis [which they reported as synonymous with T. mannii], known as 'mebange' to the Fang, is distinguished by its globular fruits. Its roots were also reported to be useful in the same manner as other iboga roots. These authors also reported a further distinction within T. iboga, analysing two varieties [as well as their 'T. subsessilis' specimens – see above]. One, known by the Fang as 'sese' and by the Mitsogho as 'ñoke', was reported to be distinguished by its long, narrow fruit pods.

The other, known by the Fang as 'minkolongo' and by the Mitsogho as 'mbasoka', was reported to be distinguished by its wide leaves and ovoid fruit, and was widely cultivated in coastal Fang villages (Khuong-Huu et al. 1976). Giorgio Samorini, in a later overview, reported that the Fang and Mitsogho of Gabon differentiate between T. iboga ['iboga of the forest'] and T. subsessilis ['iboga of the village']. Samorini mentioned T. subsessilis as differentiated by its verrucose fruits (Samorini 1997a).

Prepare seeds for germination by soaking in hydrogen peroxide [2% solution] for 1 hour, and remove all traces of pulp from seeds. Sow between moist paper towels [sealed in a zip-lock bag or wrapped in plastic if in a cold, dry environment] or in sterilised river sand in a humidity chamber, and keep in a warm, bright place. Check for mouldy seeds, and change paper towels if discoloured. Seed may take from 10 days to two months to germinate; at first sign of such, sow 2.5cm deep in sterilised seed compost, and water with 25% fungicide solution. When established, transfer to a pot or ground plot in compost; benefits from occasional fertilisation. Keep soil wet, but not waterlogged. Outside of its natural habitat, the plant will grow under 25% shadecloth in a greenhouse that gets good sun exposure, with high [c.70%] humidity inside the greenhouse. Leaf propagation [see **Psychotria**] might possibly be a viable option for cultivating this plant without seed (pers. comms.).

TACHIGALIA

(Leguminosae/Caesalpiniaceae)

Tachigalia paniculata *Aubl.* **(T. angustifolia** *Miq.***; T. eriocalyx** *Tul.***; T. sericea** *Tul.***)** – kö'-ma-na, ma-ka-pê-tê, mo-ka-pê-tê, barbasco

Tachigalia ptychophysca *Spruce*

In the Colombian Amazon, the Taiwano boil and eat the unripe seedpods of these two plants as an aphrodisiac. An infusion may also be vigorously rubbed over the chest to treat chest-pains, or to apply to ant-stings. The Makuna of Rio Apaporis rub a leaf decoction of T. paniculata on aching limbs as an analgesic. The Kubeo use the ashes of the burnt leaves for chewing with their coca powder [see **Erythroxylum**]. The Tikuna use a tea of T. paniculata as a powerful stimulant, and a decoction of the seedpod is used as a strong emetic (Schultes & Raffauf 1990).

T. paniculata has given negative results in alkaloid screening (Schultes & Raffauf 1990), though others found an 80% ethanol extract of the inflorescences to contain 0.009% *tryptamine* and 0.005% *N-methyltryptamine* (Svoboda et al. 1979).

Leaves of the related T. myrmecophila have yielded skatole [3-methylindole] and tannins (Svoboda et al. 1979).

Tachigalia paniculata is a tree c.6-15m tall, with an outspread leafy crown; young branchlets and petioles minutely tomentose, greyish or pale tawny, becoming glabrate. Leaves 4-6(-8)-jugate; leaflets ovate-oblong to elliptic, rarely almost narrowly oblong, acuminate, base unequal, rotundate or acute, c.7.5-15cm long, glabrous, or sometimes when young minutely puberulous or sericeous and shiny-white beneath, when mature often glabrous on both sides, shiny above, coriaceous, pinnately-veined, reticulate-venulose; petiolules short, thick; petioles c.7.5-15cm long, thick, acutely 3-angled or sometimes almost 2-winged, terminating in a bristle; stipules caducous, foliaceous, lanceolate or ovate, c.1.2cm long, laterally narrow, often very small. Racemes in upper axils, simple, terminally branched, shortly pedunculate, first short and densely-flowered, becoming c.30cm long, panicle base foliate, rhachi angulate or above subterete, tomentose canescent, rusty-red or pale-yellowish vestite; bracts from base broadly subulate, caducous; pedicels short, thick, c.2-4mm long; calyx tube strongly oblique, turbinate, costate, c.5-6mm long, lacinia subequal in length; limb 5-segmented, suborbiculate, obtuse, c.6mm long, at bottom otherwise small; petals 5, yellow, base dark-pilose, broadly obovate or suborbicular, calyx somewhat longer, at top equal, concave, otherwise not very oblique; stamens 10, declinate, incurved-ascending; filament bases dark-bearded, 7 less than half as long as petals, 3 larger, shortly oblong. Ovary above disc subsessile, reddish-hirsute or tomentose; style filiform; stigma terminal, very small. Legume shortly stipitate, oblong, plane, becoming glabrate; seeds ovate, compressed, slenderly albuminate.

In forest along Amazon & Solimoës rivers, and around Rio Negro near Manáos, Brazil; also in Surinam, French Guiana & Guyana (Fridericus & De Martius ed. 1965-1975).

TAGETES

(Compositae/Asteraceae)

Tagetes erecta *L.* **(T. major** *Gaertn.***; T. patula** *L.***)** – kobac piH, African marigold, Aztec marigold, French marigold, big marigold, flor de muerto

Tagetes lucida *Cav.* **(T. anethina** *Sessé et Moc.***; T. florida** *Sweet***; T. gilletii** *De Wild.***; T. pineda** *La Llave***; T. schiedeana** *Less.***; T. seleri** *Rydb.***)** – yauhtli ['the dark one'], pericon, anisillo, curucumin, flor de Santa Maria, hierba de Santa Maria, hierba anis, hierba de nube ['cloud herb'], tzitziqui, tumutsali, sweet mace, sweet-scented marigold, Mexican tarragon

Tagetes minuta *L.* **(T. bonariensis** *Pers;* **T. glandulifera** *Schrank***; T. glandulosa** *Link***; T. porophyllum** *Vell.***)** – Inca marigold, stinking roger, muster-John Henry

As 'yauhtli', T. lucida was used in sacrifice by the Aztecs – the powdered herb being thrown or blown into the faces of sacrificial victims [pre-sacrifice] to 'dull their senses' during the festivals of Huehueteotl. Sometimes today, it is used in cleansing ceremonies by shamans in the Mexican state of Morelos, and is sometimes burned as incense. It is also important in modern-day Mexican celebrations of the feast of St Michael, which replace the festivals of Huehueteotl – on the afternoon of Sep. 28, the flowers are collected and bunched together to form crosses, which are nailed over doorways to protect against devils during that night. The herb was also smoked to 'aid clairvoyancy'. It has also been said that the herb "alleviates crazy people and those astonished and frightened by the thunder" (Diaz 1979; Nicholson & Arzeni 1993; Siegel et al. 1977). A tea of the herb is sweet and anise-flavoured [see **Pimpinella**, **Illicium**]; several cups can have strong stimulating effects (Neher 1968).

T. lucida is also smoked by the Huichol for either recreation or ceremony, either alone or mixed 1:1 with tobacco [**Nicotiana** rustica, itself a potent intoxicant] – it is usually smoked alone, however, as it is more abundant than tobacco. It is usually smoked either in long, thin, cornhusk cigarettes, or in clay pipes. However taken, it is acknowledged to cause an 'intoxication', and also synergises with the tobacco – the intoxication is "marked by quiescence, lying down, a fixed gaze, and frequent periods of closed eyes...the smoker would often turn away from the fire and face the darkness". Sometimes, visual images are reported from behind closed eyes, accompanied with nausea and vomiting. Often, the herb is smoked to accompany ingestion of peyote [see **Lophophora**], fermented maize drinks ['quino' or 'nawa'], cactus distillate ['cai' or 'sotol'] or other alcohol ['tepe'], all of which help produce a stronger psychotropic effect than the herb produces alone. T. lucida also has its more everyday uses – it is crushed and held against the face as an aromatic inhalant, used in offerings, baptisms, and relaxing baths for rheumatism, and made into a tea to promote relaxation and sleep. The plant juice relieves insect bites, and the plant itself also acts as an aphrodisiac, antipyretic, emmenagogue, galactagogue, ecbolic, diuretic, fumigant and insect repellant (Diaz 1979; Jiu 1966; Nicholson & Arzeni 1993; Siegel et al. 1977). The dried, powdered leaves are used as a cooking spice; in Australia, T. lucida is commonly found as a culinary herb for sale in nurseries (pers. obs.). With T. lucida and T. minuta foliage, up to 2g dried, powdered herb taken orally with fruit juice was found to bring about a 'lucid' state with effects including "clarity, alertness, closed-eye visuals, body warmth, body tingles, feeling of well-being, and some time-distortion", as well as dream enhancement; effects lasted 2-3hrs. An alcohol tincture also worked, but lost activity after a week; a simple tea was not found to have any psychoactivity. When taken orally it was observed that eating something minimal [such as a cracker] appears to aid intestinal absorption (Lazar 2002).

T. erecta flowers are used by the Mixe of Oaxaca, Mexico, in divination. For this purpose, 9 flowers are macerated in hot water, and then strained out with a cloth; the juice is poured into a gourd of spiced maize gruel, and consumed at night to "uncover pending misfortune and all that is hidden". The seeds have sometimes been placed in another's food to harm them (Lipp 1990).

Flowers of T. erecta are sacred to Shiva in India and Nepal, and are used in offerings and worn by saddhus at festivals. Its flowers are also the source of a yellow dye (Hartsuiker 1993; Neher 1968; Rätsch 1992). T. erecta leaves are boiled by the Tikuna of the Amazon, and the cooled liquid is dropped into the eyes to relieve pain; it may also be bathed in to treat fever (Schultes & Raffauf 1990). The leaves and juice are said to be drunk as an aphrodisiac, stimulant and muscle-relaxant in Mexico, ground with water or wine, or decocted. T. erecta ia also extracted into liquid and drunk as a calmative in Argentina (Neher 1968). The leaf of T. minuta is said to be used in S. America as a stimulant, hysteria remedy, diaphoretic, anthelmintic, diuretic and emmenagogue; the plant juice is irritant to the skin and eyes. It is also decocted and drunk as a stimulant in Argentina. In Basutoland, Africa, the leaf is burned to ash and mixed with tobacco [see **Nicotiana**] for snuffing (Neher 1968; Watt & Breyer-Brandwijk 1962).

T. erecta contains pyrethrins (Cashyap et al. 1978), tagetiin, patuletin, allopatuletin, isoeuparin, quercetagitrin, galetin, rubichrome, 5-(3,4-diacetoxy-1-butyryl)-2,2'-bithiophene, 5-ethynyl-5'-(1-propynyl)-2,2'bithiophene and 5-(1-propynyl)-5'-vinyl-2,2'-bithiophene (Buckingham et al. ed. 1994).

T. lucida contains thiophene-derived terpenoids (Diaz 1979); a leaf extract acted as a CNS-depressant in rats (Jiu 1966).

T. minuta may yield 0.5-2% volatile oil [which is dark, sticky and strong-smelling], containing linalool, carvone, tagetone and either myrcene or ocimene (Watt & Breyer-Brandwijk 1962); it has also yielded pyrethrins (Cashyap et al. 1978), fumaric acid, phenyl-acetaldehyde, 4-

(2,2'-bithiophen-5-yl)-3-butyn-1-ol, 5-(4-chloro-3-OH-1-butynyl)-2,2'-bithiophene (Buckingham et al. ed. 1994) and α-terthienyl. The essential oil has shown tranquillising, spasmolytic, hypotensive, bronchodilatory and antiinflammatory activities (Rastogi & Mehrotra ed. 1990-1993); anxiogenic and antidepressant activity was also reported in rats, appearing to be due to negative modulation of *GABA* receptor systems (Martijena et al. 1998).

Tagetes lucida is a strongly-scented (reminiscent of anise and/or liquorice) perennial herb, to c.45cm high or more, freely branching, or simple and unbranched; stem terete, turning reddish, c.30cm, branches opposite, glabrous. Leaves opposite, sessile, simple, ovate-lanceolate, connate, margins serrulate, punctate with oil glands, tips of serrulations reddish, ciliate. Inflorescence consists of heads in dense terminal corymb- or cyme-like clusters, +- 10-12mm diam., 2-3-rayed, usually yellow to yellow-orange; peduncles short, without bracts, often biflorous; common calyx simple, monophyllous, tubulose, apex 9-dentate; corolla composite, deep yellow; hermaphrodites many in disc, tubulose, limb 5-fid, lacinia acutely villose; females 3(-4) radially, rotundate, subcrenate; stamens in female none, in hermaphrodites 5, short; anthers yellowish, cylindric. Ovary oblong, fertile; style filiform; stigma reflexed. Involucre c.1cm long, uniseriate, glandular-punctate, narrowly cylindrical with acute teeth. Achenes with aristate pappus of 2-3 short, obtuse scales and 2 longer awn-like bristles; seeds linear, compressed.

Mexico [esp. abundant in states of Nayarit and Jalisco], Guatemala. Cultivated horticulturally as an ornamental condiment/medicinal herb (Bailey & Bailey 1976; Cavanilles 1794; Schultes & Hofmann 1980). T. minuta occurs as an introduced weed in many areas, such as Australia [WA, SA, Qld, NSW, Vic].

To harvest, the Huichol cut off the top 15cm or so of branch, holding flowers and upper leaves, and hang it in bunches to dry in the shade of their homes (Siegel et al. 1977).

Root secretions of some Tagetes spp. repel rose, tulip and potato eelworms; T. minuta root secretions also deter some herbs or weeds, such as **Convolvulus**, couch-grass and ground ivy (Bremness 1994).

TANACETUM

(Compositae/Asteraceae)

Tanacetum boreale *Fisch. ex DC.* **(T. vulgare ssp. boreale** *(Fisch. ex DC.) Löve et Löve***; Chrysanthemum asiaticum** *Vorosch.***)**

Tanacetum cinerariifolium *(Trevir.) Sch. Bip.* **(Chrysanthemum cinerariifolium** *(Trevir.) Vis.***; Pyrethrum cinerariifolium** *Trevir.***)** – pyrethrum, Dalmatian daisy, Dalmatian pellitory

Tanacetum vulgare *L.* **(T. audibertii** *(Req.) DC.***; Chrysanthemum tanacetum** *Vis.***; C. vulgare** *(L.) Bernh.***)** – tansy, golden buttons, batchelor's buttons, solucanotu

The name of this genus and of 'tansy' derives from the Greek 'athanasia' ['immortality', or its elixir]. A classical legend tells of the beautiful young shepherd Ganymede, who was made immortal by an 'athanasia' brew, so that he would serve forever as Zeus' cup-bearer and lover. However, Zeus' wife, Hera, became jealous, and Ganymede was changed into the constellation of Aquarius (Bremness 1988; theobromus pers. comm.). T. vulgare was often used to preserve corpses; similarly, in times before refrigeration, meat was sometimes wrapped in 'tansy' leaves to preserve and flavour it, as well as repelling flies; it is also known to repel aphids, ants, fleas, mice and intestinal worms (Bremness 1988, 1994; Simonetti 1990). It is used by the Cherokee as a tonic and to treat back ache (Hamel & Chiltoskey 1975). The root is reputed to be an excellent remedy for gout. Tansy-flavoured cakes called 'tansies' were a traditional Easter food in Britain, though they are rarely made today (Grieve 1931).

T. vulgare acts as a nerve tonic, stimulant, anthelmintic, diaphoretic and emmenagogue; it may be toxic in large doses, causing vomiting, convulsions, respiratory and circulatory depression and coma, sometimes death. It should not be used by pregnant women (Foster & Caras 1994; Hutchens 1992; Mabey et al. ed. 1990). Tansy has also been used as a bitter and strongly-stimulating tea by some **Cannabis**-smokers in England (theobromus pers. comm.). Otherwise, the herb may be smoked for psychoactive effects (pers. comms.). The related T. cinerariifolium is dried, powdered, extracted in alcohol and diluted with water for use as an insecticide (Bremness 1994); in humans, this extract can cause CNS and PNS excitation, sometimes with convulsions (Katzung & Trevor 1995).

T. boreale essential oil contains *thujone* and isothujone, as well as 2,6,6-trimethyl-2-vinyl-5-OH-tetrahydropyran [major component], 2,6,6-trimethyl-2-vinyl-5-acetoxytetrahydropyran, and 2,6,6-trimethyl-2-vinyl-5-ketoxyhydropyran (Dembitskii et al. 1985).

T. cinerariifolium contains pyrethrins in aerial parts, mainly in flower heads; these consist of pyrethrin I & II, cinerin I & II, jasmolin I and jasmalin II (Cashyap et al. 1978).

T. vulgare has yielded 0.15% essential oil, consisting of 66-95% *thujone* [some chemical races contain none], 29.6% *camphor*, 24.7% umbellulone, 6% sabinene, 2.5% camphene, 5.1% 1,8-cineole, 1.5% terpinen-4-ol, 0.8% *borneol*, 1% p-cymene, 6.8% thymol, 0.7% carvone, 0.4% valeranone, 0.2% sabinol acetate, carvomentone, carvotanacetone, isopinocamphone and camphone; the herb has also yielded artemisone, piperitone, acacetin, armexifolin, crispolide, eupatillin, tanacetin and many other minor compounds (Battaglia 1995; Buckingham et al. ed. 1994; Chiej 1984; Hall 1973; Lawless 1995; Schearer 1984; Turner & Szczawinski 1991).

Interestingly, the related 'feverfew' [T. parthenium] has yielded 0.00014-0.00025% *melatonin* (Murch et al. 1997).

Tanacetum vulgare is an aromatic perennial herb; stems 30-150cm, branched above. Leaves alternate, pinnatipartite to pinnatisect, glabrous to sparsely hairy, glandular-punctate, lower cauline leaves more than 5cm, petiolate, oblong to oblong-ovate, the segments pinnatisect to pinnatilobed, linear-lanceolate to oblong-elliptical, upper cauline leaves similar but sessile. Capitula (5-)10-70(-100) in a dense, terminal compound corymb, rarely solitary, with or without ligulate florets; involucral bracts in 3 rows; involucre 5-8mm diam.; receptacle convex to subglobose, usually punctate-tuberculate; outer row of florets tubular, female, zygomorphic, 3-toothed, rarely shortly ligulate, or actinomorphic, 5-toothed, hermaphrodite, yellow, inner florets hermaphrodite, tubular, 5-toothed; stamens 5, epipetalous; anthers usually connate into a tube around the style. Ovary inferior, 1-locular; ovule solitary, basal, anatropous; style solitary, with 2 stigmatic branches. Achenes 1.2-1.8mm, 5-ribbed, with scattered epicarpic, sessile, transparent, non-mucilaginous glands; pappus 0.2-0.4mm.

Roadsides, river-gravels and waste places, in dry soil, in sun or part shade; extensively cultivated, and in some regions naturalised; almost throughout Europe (Tutin et al. ed. 1964-1980); in Australia naturalised in South Australia, Queensland, New South Wales, Victoria and Tasmania (Hnatiuk 1990).

TANAECIUM

(Bignoniaceae)

Tanaecium nocturnum *Bur. et K. Sch.* **(Osmhydrophora nocturnum** *Barb. Rodr.***)** – koribo, sape-mandur, erchu-chuá

The Paumari of the Brazilian Amazon use the leaves of this plant to make a shamanic snuff, known as 'koribo-nafuni'. It is prepared by roasting, pulverising and sifting the leaves, and mixing them with tobacco [see **Nicotiana**] prepared in the same way. This is taken by male shamans prior to diagnosing patients, and during ritual occasions. It makes a person dizzy, and feel like throwing themselves in the nearest body of water, as well as causing headache. A tea of the root bark [c.2 tab.] is used by women, producing "drowsiness, an inability to concentrate, and reduced awareness". The Choco of southern Colombia use it as an aphrodisiac. The Tikuna regard the plant as being poisonous. Some field researchers have experienced psychoactive effects simply from inhaling the plant's aroma. One felt so dizzy in a room in which the plants were hanging that he had to crawl out on all fours (Prance et al. 1977; Schultes & Raffauf 1990)! On a more benign note, the Yanomamo cook the leaves and rub the juice on the skin to relieve itching (Milliken & Albert 1996).

The leaves have a scent reminiscent of almond oil [see **Prunus**], and contain hydrocyanic acids in high concentrations, as well as saponins (Prance et al. 1977; Schultes & Raffauf 1990). However, it is unlikely that much HCN would survive the preparation of the snuff.

Tanaecium nocturnum is a lofty climbing shrub. Leaves large, conjugate, tendrilled terminally, simple, generally strongly persistent (rarely weakly caducous), fairly long petiolate, blade broadly elliptic, shortly acuminate, base acutely cordate, subtrinerved, c.14cm long, 10cm wide, besides basal nerves, 3-4 approximate lateral veins, transversely connecting lengthwise. Inflorescence decussate, few-flowered racemes; bracts and bracteoles caducous, 1.5-2mm long; rachide robust, alternate, complanate; raceme rachis 7cm long, 5-8 flowered; peduncles 12-20mm long; calyx tubular, irregular above, lobulate, with glands near base, 2.2-2.5cm long, coriaceous, trilobed; corolla white, 16cm long, lips obtuse, c.3cm long, recurved, tube narrowly cylindric, upper part of throat gradually widening, puberulous within beyond base; stamens 8-9cm, basally affixed in corolla tube, theca divaricate, arranged vertically, smaller ones 5.5cm, larger ones 6cm long. Disc moderately long, excavate above, 2.5-3mm high; ovary oviform, 5-6mm long, covered with small scales, base sessile, +- angustate; ovules many, as locules affixed in 4 rows, compressed, anatropous, erect; style exserted, c.15cm long; stigma rhomboid. Capsule scandent, often glabrous, thickly subcylindric or broadly elliptic in transverse section, woody; valves smooth externally; seeds many, compressed or saddle-shaped, nucleus and margin thick or ulterior membranaceous.

In young forest, upper Amazon, near Rio Purus and Mandos; Brazil (Fridericus & De Martius ed. 1965-1975).

TARCHONANTHUS

(Compositae/Asteraceae)

Tarchonanthus camphoratus *L.* **(T. abyssinicus** *Sch. Bip.***; T. camphoratus var. litakunensis** *(DC.) Harv.***; T. minor** *Less.***)** – Hottentot tobacco, wild cotton, sage wood, guitar wood, wilde-salie, kamferhout, kamferbos, sieriehout, vaalbos, veld-vaalbos

The leaves of this African shrub were once smoked by the Hottentot and Bushmen, and chewed by Mohammedans, for their 'narcotic' effect. Modernly, T. camphoratus is more commonly used as an analgesic. The Suto inhale smoke from the burning green branches to relieve headache. The Rolong do the same with the green root, and also smoulder green twigs to smoke rheumatic joints. They also infuse the leaf for stomach complaints. Early Cape settlers used a leaf infusion or decoction as a diaphoretic and asthma remedy, as well as an analgesic for toothache. The heavy wood from this plant is also used for fancy woodworking, and to construct musical instruments (Usher 1974; Watt 1967; Watt & Breyer-Brandwijk 1932).

The leaves have yielded 0.107% essential oil by steam distillation (Stefanis 1925), said to contain *camphor* [of which the plant smells strongly] and tarchonyl alcohol (Watt 1967); the plant has also yielded pinocembrin (Buckingham et al. ed. 1994).

Tarchonanthus camphoratus is a large shrub with a strong balsamic odour. Leaves alternate, petioled, coriaceous, 7.6-12.7 x 1.3-3.8cm, lanceolate-oblong or obovate, acute at base, subacute or obtuse at apex, entire or denticulate, young leaves densely velvety above, adult glabrous, finely reticulated above, reticulations either flat or hollow in the middle, as if pitted, tomentose and penninerved below. Inflorescence of terminal panicles, many-headed; heads dioecious, few or several-flowered; involucre of male flower of 5 scales, connate to their middle; of the female, of many separate scales, in a double row; receptacle hairy; corolla tubular-campanulate, 5-toothed, externally hairy and viscid, glabrous within. Male: anthers exserted, connate, with long setose tails and glabrous filaments; ovary abortive; nectary large, callous, hollow at top, simulating an ovary; style filiform, scarcely 2-lobed at point. Female: stamen abortive; nectary none; style exserted, bifid, lobes revolute. Achene very wooly, without pappus.

Common throughout S. Africa (Harvey & Sonder 1984).

TASMANNIA

(Winteraceae)

Tasmannia glaucifolia *J. Williams* – fragrant pepper bush

Tasmannia lanceolata *(Poiret) A.C. Smith* **(Drimys lanceolata** *(Poir.) Baill.***; Winterana lanceolata** *Poir.***)** – mountain pepper bush

Tasmannia pupurascens *(Vickery) A.C. Smith* **(Drimys purpurascens** *Vickery***)** – broadleaved pepper bush

Tasmannia xerophila *(Parm.) M. Gray* – alpine pepper bush

Leaves and fruits of these eastern Australian shrubs have a distinct acrid, peppery taste (pers. obs.). The seeds and bark of T. lanceolata have been used as a 'native pepper' (Hurst 1942), or substitute for **Piper** nigrum [see **Piper 1**]. T. lanceolata has also been used as a stomachic and scurvy remedy, like the closely-related **Drimys** winteri [see **Canella, Drimys**] (Lassak & McCarthy 1990).

The essential oils found in some members of this genus contain phenylpropenes and terpenoids which may be of interest.

T. glaucifolia essential oil yielded 5.8-16.9% *safrole*, 0-1.4% *eugenol*, 0.3-3.3% *croweacin*, 0.5-5.3% *myristicin*, α-thujene, α-*pinene*, β-*pinene*, sabinene, myrcene, phellandrene, limonene, p-cymene, 1,8-cineole, γ-terpinene, linalool and others.

T. lanceolata essential oil yielded mainly *pinene* and 1,8-cineole, as well as 0-5.1% *eugenol* and many other minor constituents.

T. purpurascens essential oil yielded mainly limonene and sabinene, as well as 1.5-4% *eugenol*.

T. xerophila essential oil yielded mainly α-*pinene*, α-phellandrene, and limonene, as well as 1-4.8% *eugenol* and 2.7-8.4% *myristicin* (Southwell & Brophy 1992).

Tasmannia glaucifolia is a 2-3m tall bushy shrub, with glossy maroon branchlets. Leaves alternate, sessile, aromatic when crushed, usually 4-6cm x 4-15mm, oblanceolate, with fine oil dots, lower surface glaucous and densely papillose. Inflorescence at first apparently a terminal umbel with single flowers in axils of closely spaced bud scales, becoming pseudowhorled by further growth of the shoot; apical buds scaly, glabrous; flowers usually white, sometimes yellow, c.5mm diam., usually unisexual; sepals fused, completely enclosing the bud, splitting into 2-3 lobes, often falling early; petals absent; stamens numerous, hypogynous, free, with slender filaments. Ovules 1-several, usually marginal; carpels 2-3, sessile, folded longitudinally, free, with stigmatic surface extended along suture; sterile carpels often present in male flowers. Fruit a cluster of berries, globose to ovoid, c.5mm diam., glossy, deep purple-black, 1-3 sessile on peduncle usually 5-10mm long. Fl. Nov.-Dec.

Along small creeks or drainage lines, near or along edge of Nothofagus moorei rainforest, 1200-1550m; Australia [New South Wales, recorded from Barrington Tops, Ben Hall's Gap and Point Lookout] (Harden ed. 1990-1993).

TAXUS

(Taxaceae)

Taxus baccata *L.* – English yew, Himalayan yew, manduparni

Taxus brevifolia *Nutt.* **(T. baccata ssp. brevifolia** *(Nutt.) Pilg.***; T. baccata var. brevifolia** *(Nutt.) Koehne***; T. baccata var. canadensis** *Benth.***; T. bourcieri** *Carriere***; T. lindleyana** *A. Murray***)** – Pacific yew, western yew

Taxus spp. – yew, ground hemlock, tree of death

Yews are very long-lived trees, being able to survive for 1,000 years or more. Bows and axe handles made from their wood have been found with a 5,000 year-old human corpse in the European Alps (Bremness 1994; Chiej 1984). Magic wands were also often made from yew wood, and the yew was sacred to the Druids, who associated it with immortality, and planted it at holy sites (Chevallier 1996). The Gauls reputedly used the juice of yew leaves to poison their arrows. It has also been reported that "the exhalation emanating from the tree may occasion vertigo, lethargy, and a kind of drunkenness". It was believed that one who slept for too long beneath a yew tree would never awaken (Felter & Lloyd 1898), though it has also been used in magical spells to attempt to raise the dead. The trees are a symbol of sadness, and have narcotic properties, as well as being very toxic (Cunningham 1994; Ott 1993; Turner & Szczawinski 1991). Slips of yew were an ingredient of the witch's potion in Shakespeare's 'MacBeth'. Native Americans of the Pacific n.w. sometimes smoke T. brevifolia leaves alone or mixed with 'bearberry' [see **Arctostaphylos**]; they are said to make one dizzy. The Klallam also use it as an analgesic (Ott 1993). In Nepal, T. baccata ssp. wallichiana ['barma salla'] is used as a shamanic incense (Müller-Ebeling et al. 2002).

A cooled leaf decoction of T. baccata is sometimes given to nervous, twitchy stock animals for its mild paralysing effect. The foliage may also be smouldered to repel mosquitos. In n. India, leaves and fruits of T. baccata are used as a sedative, antispasmodic and emmenagogue; the leaves alone are used to treat "hysteria, epilepsy and nervousness". Yew is also said to be able to procure abortion and restore menstrual flow (Bremness 1994; Chiej 1984; Nadkarni 1976). Some pagans in modern Britain have claimed that yew is 'hallucinogenic'. However, one person who suffered an accidental intoxication from inner bark powder through cuts in the hands, described "uncomfortable vomiting, aching joints and everything for a few days, and a mildly visual delirium". He further reported, "I have had more pleasant flu and would recommend avoiding this one" (theobromus pers. comm.)!

Yew leaves are considered to be the most toxic part, but the aril [minus the seed] is actually edible and sweet [though some don't like the texture]. Several seeds may kill a child. Symptoms of yew poisoning include drowsiness, dizziness, stiffness, trembling, abdominal pain, fever, nausea, vomiting, dry throat, diarrhoea, rash and pallor; severe poisoning also gives rise to irregular heartbeat, dilated pupils, convulsions, collapse and coma, followed by slow pulse and weak breathing, and sometimes death (Felter & Lloyd 1898; Turner & Szczawinski 1991). Today, yews [particularly T. brevifolia] are a source of taxol, a potential anticancer treatment, due to its ability to prevent cell division in humans (Bremness 1994; Chevallier 1996).

T. baccata leaves and twigs have yielded 0.93% taxine [a complex mixture of alkaloids, absorbed rapidly by human digestive system; may cause death due to cardiac and respiratory failure] and 0.0017% *ephedrine* (Callow et al. 1931; Gulland et al. 1931; Henry 1939; Turner & Szczawinski 1991), as well as taxicotine, milossin, tannins, resin, and an essential oil (Chiej 1984); some varieties also contain taxol (Chevallier 1996). Taxus spp. may contain the cyanogenic glucoside taxiphyllin (Conn 1973).

Taxus brevifolia is a tree 10-25m tall, with a straight, often fluted trunk, 20-120cm diam., with slender, spreading or drooping branches; bark c.6mm thick, covered with small dark reddish-brown scales; wood durable, elastic. Leaves 2-ranked, forming flat sprays, linear, flat, 12-16 x 1-2mm, acute, keeled above, deep yellow-green and shining above, much paler and stomatiferous beneath, margins revolute; persisting 4-5 years. Inflorescence dioecious, males and females usually on separate trees. Male flowers small globose catkins with bracts, of 4-8 stamens; pollensacs several, pendent in a circle around the filament. Female flowers solitary on rudimentary axillary branches, minute and green, fleshy apical discs with a few scales at base, maturing in autumn. Seed with a bony integument, ovate-oblong, c.8mm long, surrounded but free from the thickened, gelatinous, sweet, scarlet, cup-shaped aril.

In deep, coniferous woods in moist situations, widely distributed,

but rarely forming groves; Pacific n.w. region of North America (Abrams 1940-1944).

TELIOSTACHYA

(Acanthaceae)

Teliostachya lanceolata var. crispa *Nees* **(Asteracantha longifolia** *(L.) Nees***)** – toé negro

This plant is commonly used to treat stomach ache by the Siona and Secoya of Ecuador (Ott 1993), yet the Kokama of Amazonian Peru have some more interesting purposes for its use. As 'toé negro' ['toé' normally being a name for **Brugmansia** suaveolens], it is either used as an additive to their ayahuasca potions [for which 2 branches of it are boiled with 'yajé' vine (see **Banisteriopsis**) for 11 hours], or it is taken alone as an intoxicant [for which 10 leaves are boiled gently for 7 hours]. The effects of the plant are very strong, and are said to last for 3 days, during which time the shaman converses with the spirit of the plant. People also sometimes go blind for the duration of the effect (Schultes 1972; Schultes & Raffauf 1990).

Apparently the plant contains no alkaloids (McKenna et al. 1984a), yet some of the effects described allude to tropane-alkaloids or chemicals of similar pharmacology being present.

Teliostachya lanceolata var. crispa is a low-growing perennial shrub, multi-stemmed, stems repent, simply branched, branches erect. Leaves subentire, lanceolate, recurved, margin undulate-subcrenate, repand, decurrent to petiole, beneath (especially in midrib) greyish-white pubescent-hirsute, decurrent to petiole. Inflorescence a dense, terminal spike, cylindrical, verticillate, regular, interrupted at base, entirely fertile; bracts equal, many, subsessile, acute-setaceous; flowers small; calyx 5-fid, acute-setaceous, lobes oblong, subequal; corolla bilabiate, upper labia obtuse, bidentate, lower labia trilobed, lobes similar shape; stamens 4, didynamous, subincluded, united; anther bilocular, locules parallel, ovate. Capsule bilocular, bivalvate, at base 4-seeded, dissepiment rigid; seeds compressed.

Maynas [Peru] and around Amazon River (Fridericus & De Martius ed. 1965-1975).

TERMINALIA

(Combretaceae)

Terminalia bellerica *(Gaertn.) Roxb.* **(T. belerica** *Roxb.***; Myrobalanus bellirica** *Gaertn.***)** – belleric Terminalia, bahera, bahera nut, bastard myrobalan, belleric myrobalan, bedda nut, aksha, vipitaka, vibhitaka, rale-daru, baleela, ba ru ra, pili lè, mao-he-zi [fruit in TCM]

The fruits of this tree, which are acid-sweet and plum-like, are called 'belleric myrobalans', or simply 'myrobalans' [different types of myrobalan come from different Terminalia spp.], and are exported from India in large quantities. They are eaten raw or in preserves, and are also used for dyeing and tanning; the fresh fruits are eaten by monkeys, deer, sheep and cattle. In Ayurvedic medicine, the purgative dried fruits are used for stomach disorders; the dried pulp of one fruit is a sufficient dose. The fruit improves lung function and eyesight, also acting as an antipyretic and rejuvenative tonic. A fruit decoction is used as an eye lotion, and in some countries the plant is used to poison fish. The dried kernels are eaten by the Lodha of w. Bengal for 'hallucination', and this property is apparently known throughout s.e. Asia. In IndoChina, the fruit is regarded as purgative when green, and narcotic in large doses. Some people eat them without effect, perhaps due to an insufficient quantity being consumed. It is said that drinking water after eating the kernels helps the intoxication to 'kick in'. Symptoms first include nausea and vomiting, followed by narcosis, or giddiness and inebriation. Some yogis say that eating one kernel a day "increases the appetite for sexual indulgence". In India, fruits of the related T. chebula ['common myrobalan'] are used as a brain and eye tonic (Chopra et al. 1965; Frawley & Lad 1986; Nadkarni 1976; Pal & Jain 1989; Perry & Metzger 1980; Usher 1974), and in Nepal [as 'harro'] they are used in ritual incense (Müller-Ebeling et al. 2002).

In Africa, T. sericea is used to treat dysentery, diabetes and stomach disorders, and as an antipurgative. Deaths have occurred from drinking decoctions of the plant. In some areas, at times of planting and harvesting crops, and before hunting, a stick from the tree is put in the floor of the village shrine to pay homage to ancestral spirits. If the tree is cut when crops are growing, it is believed to bring hailstorms. In Zululand, a root decoction is used symbolically by sorcerers to kill an adversary from far away (Watt & Breyer-Brandwijk 1962).

In Australia's north, inner bark of T. carpenteriae is made into a paste with cold water and spread over the body. This is left on for 1 day, and is said to 'indirectly increase sense of well-being', and strengthen the tone of skin and muscle. The inner bark has shown astringent and antiseptic properties (Aboriginal Communities 1988). T. arjuna has been used traditionally in India as a cardiotonic, and to treat cancer. Modern testing has shown the bark, stem and leaves to inhibit cancer cell growth (Nadkarni 1976; Pettit et al. 1996). T. ferdinandiana ['billygoat plum'] has attracted attention due to the high levels of vitamin C found in the fruit pulp [0.4-3.15%] (Low 1990).

T. bellerica fruit has yielded phyllemblin [potentiates the activity of *epinephrine*], glycosides, polyphenols, tannins and a fixed oil (Mehra & Qadry 1963); the pericarp [fruit rind] also yielded gallic acid and egallic acid (Row et al. 1962), and the seed-coat yielded egallic acid and β-sitosterol. Both fresh and dry fruits also yielded chebulagic acid, mannitol, galloyl-glucose, glucose, galactose, fructose and rhamnose (Row & Murty 1970). Seeds have yielded a cardenolide, cannogenol-3-O-β-D-galactopyranosyl-(1→4)-O-α-L-rhamnopyranoside (Yadava & Rathore 2001). Stem bark has yielded triterpene acids [bellericagenins A & B, arjungenin, belleric acid], and their glycosides [bellericasides A & B, arjunglucoside I, bellericoside] (Mahato et al. 1992).

Terminalia bellerica is a large tree 18-25m tall, deciduous in the cold season. Leaves alternate, clustered towards the ends of branches, 7.6-15.2cm long, broadly elliptic, narrowed equally at both ends, entire or slightly crenulate, exstipulate, glabrous when mature, generally punctate on upper surface, the punctations much more permanent than in other species; petiole 2.5-3.8cm long, often with glands on petiole or near base of midrib beneath. Flowers small, in simple solitary axillary spikes, lower flowers hermaphroditic, the upper flowers males; narrow bract at base of each flower, soon deciduous; bracteoles minute; calyx tube produced above the ovary with a campanulate mouth, limb of 5 short valvate triangular lobes, deciduous, pubescent; petals 0; stamens 10, inserted on calyx tube. Disc epigynous, densely hairy; young ovary always tomentose, 1-celled, inferior; style long, simple; ovules 2-3, pendulous from summit of cell. Fruit 30-35mm long, 13-19(-27)mm diam., globular, suddenly narrowed into a short stalk, smooth, covered with silky appressed hairs, giving a velvety texture, greenish-brown, when dried obscurely 5-angled; seeds solitary, exalbuminous.

Throughout India, common in the plains and lower hills [not in the desert region of w. India], extending to Sri Lanka and Malaysia [Malacca] (Hooker 1875-1897; Mehra & Qadry 1963).

TESTULEA

(Ochnaceae)

Testulea gabonensis *Pellegr.* – izombe, ake, akewe, n'gwaki, n'komi, ngron

This tree from west tropical Africa [the only member of its genus] is occasionally used for its wood, which is valued in cabinet making. It has no recorded medicinal uses that I am aware of, yet contains some chemicals of interest.

T. gabonensis stem bark yielded 2.5% alkaloids, and root bark yielded 5% alkaloids – *N-methyltryptamine* [NMT] comprised c.90% of the total alkaloids, the remaining portion consisting of *DMT*, N-formyl-*NMT* and 2-methyl-THβC. The triterpenes friedeline and friedelinol were also isolated; epi-friedelinol was identified but not isolated (Leboeuf et al. 1977).

Testulea gabonensis is an upright tree 15-18m tall; trunk cylindrical, 70-90cm diam.; wood yellow-rosy. Leaves simple, grouped at ends of branches, oblong-lanceolate, entire, slightly undulate, to 35cm long, 8cm wide; stipules fused in a triangular, acute ligule on the inner face of the petiole; petiole very short. Inflorescence simple, terminal, clustered, longer than leaves; flowers hermaphroditic, actinomorphic, white-yellowish or rosy; sepals 4, unequal, free; petals 4, 2 broad and 2 narrow, free, subsessile; stamen 1, free, of many staminodes fused into a column enclosed by the 2 large petals, filaments persistent; anther linear, basifixed, opening by terminal pores. Ovary stipitate, eccentric; ovules many; style long and curved. Fruit a bivalved capsule, opening at maturity to release seeds; seeds winged.

In primary forest; Gabon, s. Cameroon (Hutchinson & Dalziel 1954-1972 [for some family details only]; Leboeuf et al. 1977).

A description of this species is also found in Bull. Soc. Bot. France, 1924 [Vol. lxxi:76], which I have been unable to locate. Due to this difficulty, I must thank M. Leboeuf et al. for my liberal use of their 1977 article.

TETRAPTERYS

(Malpighiaceae)

Tetrapterys methystica *Schultes* **(T. squarrosa** *(Griseb.) Griseb.***; T. styloptera** *A. Juss.***; Bunchosia squarrosa** *Griseb.***)** – caapi, weé-po-awk, bee-ra-ree'-a-ma, no-ree-a-mee-see, nö-ña'-mee-koo-ma

Tetrapterys mucronata *Cav.* **(T. crebriflora** *A. Juss.***; T. glaberrima** *Benth.***; T. silvatica** *Cuatrec.***; Triopterys acuminata** *Willd.***; Tr. mucronata** *(Cav.) Räusch.***)** – kai-ee'-ree-gê, dö-yet' ['fire vine']

The Makú of the Rio Tikie of Amazonian Brazil make a cold-water infusion of T. methystica bark to prepare a 'strongly hallucinogenic' beverage. Alternately, they use the stem bark as a basis for ayahuasca [see **Banisteriopsis**]. It is decocted by the Makuna and drunk as a febrifuge. Also, the Karapana of the Rio Vaupes use T. mucronata to prepare ayahuasca. Natives of the Rio Piraparana boil the bark with **Strychnos** erichsonii bark for 4-5 hours to make a weak curare dart poison. Other species are used to treat various infections (Davis 1996; Schultes 1950, 1957; Schultes & Raffauf 1990; Uscategui 1959).

Chemistry of these plants is unknown.

Tetrapterys methystica is a scandent bush; trunk with black bark; branches ashy-yellowish, internodes 4-10cm long; branchlets terete, lightly canaliculate, grey-sericeous when young, 0.8-3.3mm diam. Leaves chartaceous, ovate, rather long acuminate, basally mostly rounded, margin entire but slightly revolute, 6-8.5cm x 2.5-5cm, strongly discolourous, upper surface bright green, minutely and remotely sericeous, under surface ashy green, rather densely sericeous and waxy; stipules small, soon caducous. Inflorescences pseudocorymbose, 4-5 flowered, much shorter than leaves, 2.5-3cm long; pedicels rather densely sericeous; bracts subulate, 1.5mm long; bracteoles ovate-triangular or suborbicular, 1.5mm long; sepals thick, pilose throughout, ovate-lanceolate, subacute, 3mm long, with 8 black oval-shaped glands 0.5mm long; petals spreading, membranaceous, mostly yellow but red or brownish in centre, elongate-orbicular or oval, apically rounded, basally obtuse, marginally subcrenulate, 4mm long, mostly 2.5mm wide, claw fleshy, 0.5mm long; stamens not included, equal; anthers allantoid, 1.3mm x 0.4mm, arcuate, filaments flattened, 1.3mm long. Ovary densely albopilose; styles equal, recurved. Samara nut sericeous, glabrescent, complanate-ovoid, 5mm x 6mm x 2mm, ventral areole ovate, c.3mm tall; wings chartaceous, brownish, lower ones obcuneiform, apically truncate-rotundate, 12mm x 2.5mm, upper ones similar but often subovate or semi-orbicular and slightly larger; dorsal wing 2.5-5mm long.

Rio Vaupes Basin, near Colombian/Brazilian border (Schultes & Hofmann 1980).

THALICTRUM

(Ranunculaceae)

Thalictrum foetidum *L.* – meadow rue

This small European herb has been found to contain an important indole alkaloid [see below], as well as a great array of isoquinoline alkaloids. While it appears to have no indigenous use, several of its relatives do.

'Columbine meadow rue' [T. aquifolium] roots are eaten raw or cooked by the Ainu of n. Asia. Roots and leaves of T. angustifolium are decocted in the Ukraine as a diuretic, and the plant is fed to cows to stimulate milk production. T. collinum, from the same broad locale, is prepared as a flower and root decoction to treat stomach aches, scrofula, urine retention and to clean wounds. Also, the Central American T. hernandezii [T. lasiostylum], known as 'alboquillo de campo', is used for its root, which is decocted as a diuretic, purgative and rheumatism treatment (Usher 1974). T. foliolosum root is used in India as a bitter tonic. It relieves fever and toothaches, and when snuffed it "clears the brain" (Nadkarni 1976).

T. dasycarpum, also known as 'meadow rue', has been administered to horses as a stimulant snuff by the Omaha [see also **Clematis**]. It is applied with white clay to the nostrils of their horses by the Pawnee, for the same reason (Morgan 1981). The Chinese T. faberi is used in folk medicine as an antiphlogistic, and is given rectally to treat stomach cancer (Wagner et al. 1984). T. minus, T. revolutum, T. rochebrunianum and T. rugosum have shown hypotensive activity in animals (Patil & Beal 1987). T. foetidum itself has been shown to possess CNS-depressant, hypotensive, antispasmodic and antiinflammatory properties (Baser & Ertan 1990).

T. foetidum root has yielded *harmine* (Shulgin & Shulgin 1997). Of specimens collected in June at Keltepe [Turkey, 1950m], aerial parts yielded thalmelatine, thalictrogamine, thalipine and argemonine [see **Argemone**]; roots yielded thalidasine, thalrugosaminine, thaligosinine, berberine and magnoflorine [see **Magnolia**] (Baser & Ertan 1990). Specimens from Mongolia yielded thalactamine, glaucine, corunine, argemonine N-oxide, berberine, *protopine*, O-methylthalicberine, thaligosine, hernandezine, thalidezine and *foetidine* (Velcheva et al. 1990). The plant has also yielded berbamine, oxoglaucine, isoboldine [blocks *dopamine*-sensitive adenylate cyclase activity], isotetrandrine, reticuline [inhibits *dopamine*-binding], ocobotrine, bisocobotrine, sinacutine, thalidasine, thalrugosidine, thalibrine, thalflavine, thalfiline, thalfinine, thalicmidine, thalicarpine [causes pressor effects and tachycardia, hypotensive in larger doses], thalfoetidine, rhamnetin and cyclofoetigens A & B (Buckingham et al. ed. 1994; Patil & Beal 1987).

Similar tetrahydroisoquinoline alkaloids are found in the many other Thalictrum spp.; some exhibit cholinergic and/or dopaminergic interactions (Patil & Beal 1987). It may be likely that some species would contain irritating compounds such as those found in the related **Clematis** and **Ranunculus**.

Thalictrum foetidum is a glandular, foetid-smelling, shortly rhizomatous perennial 10-40cm tall, with some long eglandular hairs. Leaves 2- to 3-pinnate or -ternate, about as wide as long, sometimes stipulate; basal leaves 3- to 4-ternate, without stipels; leaflets 2-4mm long, suborbicular or broadly ovate, irregularly dentate in upper half. Inflorescence a panicle with long branches; flowers small, yellow, pendent; perianth segments 4-5, usually caducous, c.3mm; honey-leaves absent; filaments slightly thickened, filiform; stigma fimbriate; stamens numerous, conspicuous. Fruit erect; achenes c.10, sessile, compressed, ovate in outline, strongly ribbed longitudinally, less than 5mm long, beak nearly as long as achene.

Mountains of east, central and southwest Europe, westwards to e. Spain. Plants from the Pyrenees and Spain do not have the eglandular hairs and may be a different species, T. minus ssp. pubescens (Tutin et al. ed. 1964-1980).

THAMNOSMA

(Rutaceae)

Thamnosma montanum *Torr. et Frém.* **(T. montana** *Torr. et Frém.***)** – turpentine broom, Mojave desert rue, cordoncillo

Kawaiisu shamans of North America have been reported to drink an infusion of this obscure plant "to go crazy like coyotes" (Ott 1993). The plant has also been used in the Mojave Desert as a tonic, and to treat gonorrhoea (Kearney et al. 1951). In Africa, T. africana is smoked by the Ndebele to treat chest complaints, and to repel fleas and ants (theobromus pers. comm.).

T. montanum roots have yielded quinoline alkaloids – 0.1% γ-fagarine, 0.075% N-methylacridone and 0.005% *skimmianine*; and coumarins – 0.05% thamnosin, 0.0275% bergapten, 0.025% isoimperatorin, alloimperatorin methyl ether, 0.025% phellopterin, 0.016% thamnosmin, 0.01% xanthotoxin and 0.0075% psoralen; 0.005% β-sitosterol was also isolated (Kutney et al. 1972). In later studies, roots and rhizomes yielded quinoline alkaloids – 0.02% robustine [potentiates effects of barbiturates], 0.094% *skimmianine*, 0.0008% acridone, 0.014% N-methylacridone and 9(10H)-acridinone; and coumarins – 0.003% thamnosmonin, 0.0012% thamontanin and 0.042% 5-(3'-methyl-2',3'-dihydroxybutanyl)-8-MeO-psoralen. Aerial parts have yielded N-methylacridone (Baumert et al. 1994; Chang et al. 1976; Harborne & Baxter ed. 1993). Shoots, leaves and seed pods [combined] yielded 0.04% umbelliprenin, isoimperatorin, 0.152% alloimperatorin methyl ether, thamnosmin, phellopterin, 0.18% isopimpinellin, 0.14% 5(2',3'-epoxy-3-methylbutyl)-8-MeO-psoralen, and possibly psoralen, bergapten and xanthotoxin. Byakangelicin has also been reported from the plant (Kutney et al. 1972).

Thamnosma montanum is an erect, rigid, glandular-dotted shrub with a strong disagreeable odour, to 80cm tall with stoutish, yellow-green, often spine-tipped branches. Leaves simple, alternate, distant, soon deciduous, linear to narrowly-oblong, 5-15mm long, sessile, subfleshy and conspicuously pellucid-dotted. Flowers perfect, racemose; sepals 4, deltoid to broadly ovate, 2.5-3.5mm long, rounded or infrequently acute at apex; petals 4, almost erect, purplish, oval to oblong, 8-14 x 4-5mm, glandular-pellucid; stamens 8, +- equalling petals, with subulate or filiform filaments and inserted on an entire or crenate cup-shaped disc; anthers apiculate. Ovary stipitate, 2(-3)-celled, bilobed; ovules 5-6 in each cell; style filiform, slender, exserted 3-6mm; stigma capitate. Capsule 10-13mm wide along greatest diameter, 6-9mm high, on a stout stipe to 10mm long, opening apically; seeds 1-3 in each cell, cochleate-reniform, 4-6mm long, smooth or finely wrinkled, brown to black, dull. Fl. Feb.-Apr.

Grows on desert slopes and rocky mesas (Shreve & Wiggins 1964), generally in warm desert shrub communities and in Yucca brevifolia, Pinus spp. and **Juniperus** spp. woodlands (pers. comm.); mainly Lower Sonoran Zone, w. margins of the Colorado Desert, Mojave Desert, and to s. Utah, s.w. Arizona and n. Baja California (Shreve & Wiggins 1964).

THEOBROMA

(Sterculiaceae)

Theobroma angustifolium *Sessé et Moc. ex DC.* **(T. quinquenervia** *Bernoulli***; T. speciosum** *Willd. ex Spreng.***)** – cacao mico, cacao de sonusco, cacao silvestre, cushta

Theobroma bicolor *Humboldt et Bonpland* – Nicaraguan cacao, cacao blanco, cacahoapatlachtli, pataxte, pataste, ninichh cacao

Theobroma cacao *L.* **(T. leiocarpum** *Bernoulli***; T. sphaerocarpum** *A. Chev.***)** – cacao, cacao tree, cocoa tree, chocolate nut tree, 'food of the gods', cacahuatl, cacaoaquauitl, cacvaqualhitl, cacao dulce, cacao-cacao criollo, cumala, hach kakaw

Theobroma subincanum *Martius* **(T. ferruginea** *Bern.***; T. tessmannii** *Mildbr.***; Cacao sylvestris** *Aubl.***)** – cupuí, cumala, mee-ñé-ro, cacao, sacha cacao, cacahuillo

'Cacao' [generally bastardised as 'cocoa'] is a popular product all over the world – even more so its major commercial byproduct, chocolate [another bastardised term – see below]. The generic name Theobroma means 'food of the gods'. Believed to be native to the northern Amazon basin, T. cacao is also naturalised as far north as Chiapas, Mexico. Two main forms of this species are distinct – the Central American, known as 'criollo', which is of finer quality, and the South American, known as 'forastero'. 'Trinitario' varieties are intermediate forms between criollo and forastero types. True wild stands of criollo are considered rare or unknown, due to its long history of human cultivation. Cacao was the basis of a sacred beverage to the Aztecs. It was cultivated for them by the Maya and other groups then subject to Aztec rule. The harvested fruits were called 'cacvacentli', and the beans 'cachoatl'. The classic form of the beverage [often bastardised as 'chocolatl' from the Aztec 'cacahuatl'] was made from roasted, ground cacao beans, corn meal, vanilla beans [from Vanilla planifolia], 'achiote' seeds [from Bixa orellana], **Capsicum**, and a small amount of water. This was mixed and shaped into cakes, which were dried and stored until needed. To prepare the drink, a piece of the cake was mixed with water, and whisked to make it thick and frothy. This was known to be consumed by the court of Moctezuma II. It was not exactly palatable to the unrefined tongues of the newly-arrived Europeans, who had to add sugar and cinnamon [see **Cinnamomum**] to give it an acceptable taste. Cacao is still used in this latter form in Mexico today [though the 'cinnamon' used may actually be from a **Canella** or similar plant]. In South America, however, the fruits of the tree are usually used for their edible pulp, and the seeds are discarded (Wood & Lass 1985; Young, A.M. 1994).

The Aztecs are known to have used cacao beverages as delivery drinks for **Psilocybe** mushrooms, and other sacred plants (Ott 1993, 1994). In Central America, the beans were also used as currency, and as a form of tribute or tax to the Aztec rulers. It is said that in Nicaragua during the 1500's, one could hire the services of a prostitute for 10 cacao beans. Once Cortes the Spaniard noted the use of cacao in Mexico, he was impressed by its alleged aphrodisiac properties and ordered its cultivation. It was later introduced to Europe, and its cultivation and consumption grew rapidly. 'Eating chocolate', a European invention, was not developed until 1848, and in 1879 the Swiss developed the first milk chocolate. Currently, most commercial cacao comes from S. America and Africa. T. angustifolium and T. bicolor have also been used as types of cacao, but their use is not prevalent today; however they are still sometimes used as shade trees in cacao plantations (Emboden 1979a; Wood & Lass 1985; Young, A.M. 1994).

The leaf of T. cacao is infused and drunk as a heart tonic and diuretic in Colombia; also, the Ingano use the bark, and the Karijonas use the toasted seeds, to treat some skin conditions (Schultes & Raffauf 1990). A national beverage of Nicaragua, 'piñolillo', is made from the pulp of T. bicolor fruits. A beverage made from T. cacao pulp is also enjoyed in much of S. America (Young, A.M. 1994). In the Amazon, ashes of T. subincanum bark are added to the **Nicotiana** snuff used by the Jamamadi, Deni (Prance 1972) and Tikuna (Ott 1993). The ashes derived from the leaves, twigs, bark, or dried fruit husks of this same species [and sometimes others, such as T. bicolor] are also sometimes used to coat psychotropic **Virola**-paste pellets (Schultes 1969b; Schultes & Swain 1976), or are mixed with **Virola**-paste snuff (Prance 1972; Schultes 1955a; Schultes & Raffauf 1990). See **Virola** for more details.

The major constituents of T. cacao are mild CNS stimulants. Chemical content of the beans varies depending on the stage in production. In general, the main constituents are *theobromine* [up to 2% or more] and *caffeine* [up to 0.35%] (Lindner 1956). Beans may contain c.0.03% *caffeine*; cocoa powder 0.08-0.35% *caffeine* and 1.46-2.66% *theobromine*; dark chocolate 0.017-0.125% *caffeine* and 0.359-0.628% *theobromine*; milk chocolate 0.005-0.054% *caffeine* and 0.135-0.186% *theobromine*; dark sweet chocolate 0.033-0.047% *caffeine*; white chocolate 0.014-0.028% *caffeine*; and hot chocolate 2-10mg *caffeine* and 54-94mg *theobromine* per cup (De Camargo & Toledo 1999; Gilbert 1986; Gilbert et al. 1976; Lindner 1956; Zoumas et al. 1980). Also present are *phenethylamine* and *tryptamine* derivatives, as expressed in µg/g in each of 3 stages [fermented unroasted beans; fermented roasted beans; blended cocoa] – *tyramine* [3.4; 3.6-11.6; 8.3], synephrine [4.6; 4.7; 7.5], octopamine [1.2; 29.7; 35.8], metanephrine [1.1; 1.5; 1.7], normetanephrine [1.4; 3.2; 3.5], *tryptamine* [6.2; 1.1; 2.4] and *5-methoxytryptamine* [5.0; 0.9; 0.8] (Kenyhercz & Kissinger 1977, 1978), as well as behenoyl-*tryptamine* (Ehmann 1974) and c.0.0012% *phenethylamine*. Other constituents include 0.0025-0.0044% *salsolinol*, *choline*, cacaonin, procyanidin B, leucocyanidin, phloroglucinol, caffeic acid, ferulic acid, vanillic acid, lauric acid, 2-OH-phenylacetic acid, p-coumaric acid, catechin, 1-epicatechol, protocatechuic acid, tannins, carbohydrates and fats (Buckingham et al. ed. 1994; Kenyhercz & Kissinger 1978; Melziga et al. 2000; Riggin & Kissinger 1976; Schermerhorn et al. ed. 1957-1974). Recently, *anandamide* [a cannabinoid receptor ligand], as well as N-oleoylethanolamine and N-lineoylethanolamine [these latter two chemicals inhibit the hydrolysis of *anandamide* by the enzyme *anandamide* amidohydrolase, increasing *anandamide* levels; see also *Neurochemistry*] were detected in trace amounts [0.00005-0.009%] in cocoa powder and dark chocolate (Tomaso et al. 1996). Even more recently, β-carbolines [along with the previously-found *serotonin* and *tryptamine*] were found in cacao-products, prompting several friends to comment that "if you wait long enough, everything turns up in chocolate"! As µg/g, the following compounds were found in dark chocolate, milk chocolate, cocoa powder, and chocolate cereals – 1-methyl-THβC [0.05-0.21; 0-0.1; 0.05-0.11; 0-0.03], (1R,3S)-1-methyl-THβC-3-carboxylic acid [0.53-0.88; 0.18-0.25; 0.3-0.66; 0.14-0.27], (1S,3S)-1-methyl-THβC-3-carboxylic acid [1.37-2.0; 0.47-0.59; 0.76-1.55; 0.35-0.65], THβC-3-carboxylic acid [0.23-0.68; 0.07-0.13; 0.012-0.38; 0.06-0.85], 6-OH-1-methyl-THβC [1.46-3.92; 0.43-0.68; 0.72-2.3; 0.16-0.39], *tryptamine* [0.2-1.16; 0.05-0.23; 0.068-1.33; 0-0.07] and *serotonin* [1.37-5.08; 0.13-0.87; 0.4-3.3; 0-0.18] (Herraiz 2000a).

Theobroma cacao is a wide-branching evergreen tree, 5-8m tall; twigs pubescent. Leaves alternate, oblong-oval or elliptic-oblong, entire, thick, 15cm long or less, base rounded, apex abruptly acuminate, midrib strong, side veins paired or somewhat alternate and arching; petiole short. Flowers small, in fascicles directly on bark of trunk and main branches, c.2cm across when expanded; pedicels slender, 12mm or more long; calyx rose-coloured, deeply 5-parted, segments acuminate; corolla yellowish, petals 5, with a stalk-like claw and expanded blade; fertile stamens 5, opposite sepals. Ovary sessile, 5-celled, many-ovuled; style filiform. Fruit 30cm long or shorter, mostly 10cm or less diam., c.10-ribbed, red to yellow, purplish or brown, elliptic-ovoid; rind thick, hard and leathery; cells 5, each with 5-12 seeds ('beans') in a row embedded in a white or pinkish acidic pulp (Kirtikar & Basu 1980).

The main agricultural 'races' of T. cacao may be divided into three major types, each with various subvarieties.

'Criollo' – derived from T. cacao ssp. cacao. Varieties include Mexican, Nicaraguan ['cacao real'], Colombian, 'lagarto' ['pentagona'], 'angoleta' [a rarer Nicaraguan form, with small green pods] and 'cundeamor' [another rare Nicaraguan form, with long, bright red pods more constricted at the 'neck' and with a curved apex]. Criollos are more susceptible to pests and diseases than other types.

'Forastero' – derived from T. cacao ssp. sphaerocarpum. Varieties are divided into Upper Amazonian and Lower Amazonian ['amelonado'], and include regional varieties of 'amelonado', 'cacao nacional', 'común' and 'Matina' ['Ceylan']. Amelonado is the most widely cultivated type of cacao.

'Trinitario' – intermediates between criollo and forastero; have not been found in the wild (Young, A.M. 1994).

Cacao trees may be grown in tropical areas with adequate rainfall [1250-2800mm ann.], temperature [min. 18-21°C, max. 30-32°C], high humidity, moderate wind protection and shading. They tolerate a wide range of soils, but prefer deep, well-drained soils with organic matter. Soil should be dug at least 1.5m; a mix of 50% sand, 10-20% silt, 30-40% clay is best, with good layer of organic matter on top; pH [6-]6.5[-7.5]. Plants grow best with nitrogen-fixing legumes, such as **Erythrina** spp., Inga spp. and Gliricidia spp. Cultivate from cuttings or seed. Seeds may be kept in their pods up to 7-10 days before losing viability; if coated with talcum powder they may last up to 4 weeks. The seed is planted flat 1cm deep, after removal of the mucilage; germination beds should be under heavy shade, and germination occurs in 7-15 days. Water every 1-3 days, and plant out when 4 months old. Trees bear fruit after the 2nd year; yields increase with time, reaching a maximum 8-10 years after planting. A mature tree produces, on average, 30-40 pods per year, though under good conditions hundred of pods can be obtained. Pods are ready for harvest 5-6 months after flowers have been fertilised, and remain harvestable for up to 1 month. Pods are cut from the tree without wounding the plant, which can allow mould fungi to enter; they are opened with a knife or a rock, and the beans are removed and separated from their placentas.

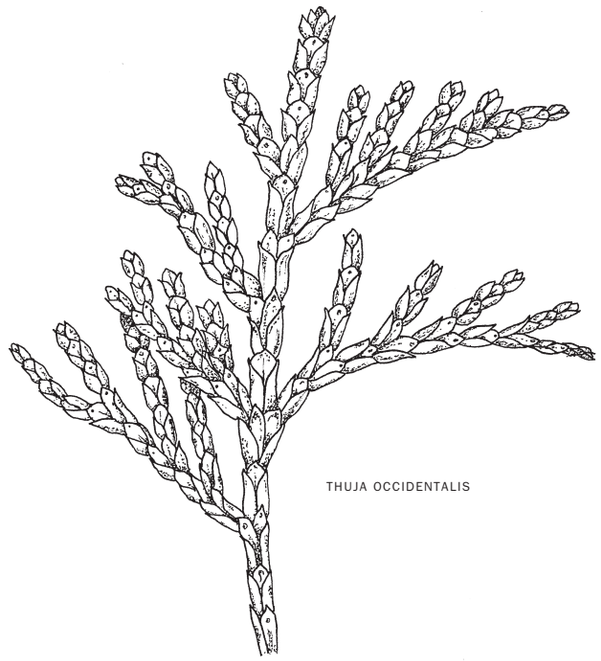
Cacao beans are fermented in boxes, baskets, or heaps for 6-8 days, with turning every 1-2 days. Drainage is allowed for, which removes most of the mucilaginous pulp in the sweat. The fermentation serves several purposes – to liquefy the pulp, kill the seed embryos, decrease astringency and bitterness, and develop the characteristic flavour and aroma. At the end of fermentation, the beans are dark and smell slightly of ammonia; they are then sun-dried, bringing moisture content down to 6-7%. The dryness can be tested by breaking half a bean – it should snap into 2 parts, and should not bend or shatter.

For chocolate making, the beans [after cleaning] are roasted at 100-120°C for 45-70min. [which helps develop the final taste and aroma], and the skins removed. The beans [more accurately now the cotyledons] are ground into 'cocoa mass' [cocoa liquor], which contains 55-58% fatty 'cocoa butter', which is mostly removed by hydraulic press [apparently much so-called cocoa butter available to the public, such as in health-stores, is

derived from coconut (Cocos nucifera)]. The remaining mass is 'cocoa powder', which still may contain 22-23% fats, and is used commercially in chocolate drinks. If the powder is re-pressed, a lower-fat [10-13%] product results, which is used for flavouring foods. Incidentally, although this cocoa butter consists of highly saturated fats, it is poorly absorbed, and scarcely affects serum cholesterol in the consumer. Chocolate is made from a mix of cocoa mass, cocoa butter and sugar, along with other ingredients specific to different types and brands. Milk is now a very common additive to chocolate, in the form of milk powder or sweetened condensed milk (Wood & Lass 1985; Young, A.M. 1994). The variety of possible additives might be limited only to the imagination, as chocolate has been used as a vehicle for psychotropic drugs including **Cannabis**, 'kava' [see **Piper 2**], Celastrus paniculatus seed oil [see *Endnotes*] and rose oil (theobromus pers. comm.).

THUJA

(Cupressaceae/Pinaceae)



THUJA OCCIDENTALIS

Thuja occidentalis *L.* **(T. obtusa** *Moench***; T. theophrasti** *C. Bauhin ex Nieuwl.***)** – arbor vitae, eastern white cedar, eastern arbor vitae, white cedar, false white cedar, yellow cedar, American cedar, feather-leaf cedar

Thuja orientalis *L.* **(Biota orientalis** *(L.) Endl.***; Platycladus orientalis** *(L.) Franco***)** – Chinese arbor-vitae, bo dze ren, bo zi ren, dhupi, mayur pankhi

Thuja plicata *Donn ex D. Don.* **(T. gigantea** *Nutt.***)** – western red cedar

Thuja standishii *(Gordon) Carrière* **(T. gigantea var. japonica** *(Maxim.) French. et Sav.***; T. japonica** *Maxim.***; Thujopsis standishii** *Gordon***)** – Thuja 'japonica'

In Europe, known as 'arbor vitae' ['tree of life'], Thuja spp. are often planted near graves and cemeteries. In Germany and England, they have had a place in folk medicine since at least the 1900's, to treat fever, menstrual disorders, and to procure abortion. Native North Americans used T. occidentalis both medicinally and mystically. Branches and inner bark were used for the same purposes as in Europe, as well as for coughs and headaches; twigs and foliage were burned as a ritual incense, and are said to protect against harmful magic. Modernly, Thuja is used in medicine for several ailments. Foliage treats bronchial, urinary and vaginal infections; twigs treat rheumatism, and their antiviral and antifungal properties are applied to treat warts and skin infections (Bremness 1994; Chevallier 1996; Rätsch 1992).

In TCM, T. orientalis seeds are taken in a 5-10g decoction as a sedative nutrient tonic, promoting semen production and tonifying the heart. Prolonged use is said to improve complexion, sharpen hearing and brighten the eyes. Leaves are also used as an astringent antipyretic, or infused in 60% alcohol for 1 week and applied as a hair tonic (Reid 1995). In Nepal, the plant is used as a shamanic incense (Müller-Ebeling et al. 2002).

Thuja spp. are fairly toxic if taken internally, leading to local irritation, long-lasting convulsions, liver and kidney damage, and bleeding from stomach mucosa (Frohne & Pfänder 1983). A more sensible route to intoxication is via smoke or vapour inhalation, but care should still be taken to avoid immoderate exposure to the fumes. These plants should be avoided by pregnant women, due to their high content of *thujone*, which is also probably one of the main inebriating principles.

T. occidentalis essential oil has yielded 60-65% *thujone*, 8-9.5% iso-*thujone*, 1% *camphor*, 1.2% camphene, 2% camphone, 14% fenchone [counterirritant], *borneol*, limonene [sedative, skin irritant, expectorant], 1.3% *pinene*, 1.8% d-sabinene, 1.2% terpinen-4-ol, 2.3% bornyl acetate and myrcene. The plant has also yielded diterpenes [including dehydroabietane, neothujic acids III & IV, (+)-7-oxo-13-epi-pimara-14,15-dien-18-oic acid, (+)-7-oxo-13-epi-pimara-8,15-dien-18-oic acid and isopimaric acid (these last 3 compounds have shown some potential anti-cancer activity)], the sesquiterpene alcohol (+)-occidentalol, lignans [including (-)-matairesinol, epi-pinoresinol, (-)-thujaplicatin methyl ether, (-)-wikstromol, (-)-deoxy-podophyllotoxin, (1S,2S,3R)-(+)-iso-picrodeoxy-podophyllotoxin and (-)-deoxy-podorhizone (these last 4 compounds have also shown potential anti-cancer activity)], a flavonoid glycoside, mucilage and tannins (Banthorpe et al. 1973; Battaglia 1995; Chang et al. 2000; Harborne & Baxter ed. 1993; Mabey et al. ed. 1990).

T. orientalis essential oil has yielded 53% *thujone*, 20% iso-*thujone* and 2% *camphor*. Leaf extracts have also yielded *apigenin*, quercitrin, cupressuflavone, kaempferol-7-O-glucoside, quercetin-7-O-rhamnoside and myricetin-3-O-α-L-rhamnoside (Banthorpe et al. 1973; Khabir et al. 1986).

T. plicata has yielded 0.8-2.3% essential oil, comprised of 76-88% *thujone*, 7-12% iso-*thujone*, 1-8% d-sabinene, and small quantities of d-α-*pinene*, d-limonene, camphene, p-cymene, 1,8-cineole, γ-terpinene, terpinolene, d-terpinen-4-ol and car-4-ene (Banthorpe et al. 1973; Rudloff 1962).

T. standishii essential oil has yielded 1% *thujone* and 27% *camphor* (Banthorpe et al. 1973).

Thuja occidentalis is a coniferous, conical tree with widely spreading branches, to 20m tall; bark orange-brown, peeling in vertical strips; ultimate branches very soft and flat, 1-2mm wide; foliage aromatic. Leaves opposite, scale-like, dark silver-green, appressed, closely imbricate, broadly ovate to rotund, 2-4mm long, obtuse, glandular, persisting on older branches for many years, becoming large and pointed. Flowers in separate clusters at the ends of shoots; perianth none. Male flowers globose, red; stamens several together, subtended by a scale; filaments +- united; anthers opposite, 2-4-celled, sacs globose, 2-valved. Female flowers ovoid or oblong, yellow-brown, small, scales opposite, with 2(-5) ovules; ovules with 2 integuments, borne on the surface of a scale. Cones oblong-ovoid, upright, yellow-green ripening to brown, coriaceous, opposite, 8-10 scales, outer scales nearly as long as inner, spreading when mature; seeds oblong. Fl. May-Jun.

In moist or wet soil in swamps, forming dense forests excluding other vegetation, and rocky mountain slopes, often on limestone; New Brunswick to James' Bay and Manitoba, s. to New Jersey, N. Carolina, Tennessee, Illinois, Minnesota (Gleason 1952).

TILIA

(Tiliaceae)

Tilia cordata *Mill.* **(T. parvifolia** *(Ehrh.) Ehrh. ex Hoffm.***)** – small-leaved lime, linden

Tilia mexicana *Schlecht.* – tilio, sirimo, jonote

Tilia tomentosa *Moench* **(T. argentea** *Desf. ex DC.***)** – linden

Tilia spp. – linden, lime tree, limeflower, tilleul

Leaves of T. cordata have been used as a tobacco additive [see **Nicotiana**] in the past (Lewis & Elvin-Lewis 1977), and in some parts of Asia imported T. tomentosa flowers [minus their bracts] are used as a tea substitute [see **Camellia**] (Landerer 1883). In Lithuanian religious rites, women make sacrifices to 'linden' trees, which in Europe may symbolise protection, luck and longevity, as well as being associated with love and Venus (Cunningham 1994). In Mexico, flowers of the endangered T. mexicana are used as a nerve tranquilliser, as well as to treat gastroenteritis, cardiac disorders, haemorrhoids and other ailments. The fresh flowers are considered more effective than dried flowers (Pavón 2000). The Winnebago of N. America use the root of T. americana ['basswood'] to treat 'female weakness' (Kindscher & Hurlburt 1998).

Very old, stale flowers of linden, particularly T. cordata, are said to be mildly intoxicating (Bremness 1994), and I have received an unsubstantiated [and most likely exaggerated] report that the fermented flowers are "hallucinogenic" (pers. comm.). A chloroform extract of commercial linden flowers [dry and old] had very potent sedative effects when smoked (theobromus pers. comm.).

Medicinally, linden flowers are infused and used as a nervine sedative relaxant; they lower blood pressure, reduce muscle tension, induce sweating, and treat colds, flu, arteriosclerosis and nervous indigestion. Water from infused flowers may also be used to bathe the skin to treat wrinkles and rheumatism. The inner bark treats kidney stones and gout, and is an antispasmodic, diuretic coronary vasodilator (Bremness 1994; Chevallier 1996; Chiej 1984; Mabey et al. ed. 1990; Polunin & Robbins

1992; Simonetti 1990).

The active agents in linden appear to reside in the flavonoid mixtures contained within, fractions of which bind to BZ-receptors (Medina et al. 1989; Viola et al. 1994). Tilia spp. flowers may yield largely the flavonoids kaempferol [MAOI (Sloley et al. 2000)] and quercetin, as well as aromadendrin [weak MAOI (Han et al. 2007)], fustin and pinobanksin; as well as tiliroside, vincetoxicoside A, c.3% mucilage, 0.02-0.1% volatile oil [including the phenylpropanoid caffeic acid (3,4-dihydroxycinnamic acid)] and tannins (Buckingham et al. ed. 1994; Chevallier 1996).

T. cordata flowers contain the flavonoids quercetin, quercitrin, hesperidin and astragalin; essential oil with farnesol and linden ether; and tannins, mucilage, saponins, sugars, acids [including ascorbic acid], carotene and manganese salts (Chiej 1984; Mabey et al. ed. 1990; Polunin & Robbins 1992).

T. mexicana leaves and flowers contain alkaloids, saponins, glucosides and an essential oil with hypotensive effects in animals (Pavón 2000).

T. tomentosa flavonoid extract had anxiolytic effects in animals; although the constituent kaempferol expressed low-level BZ-receptor binding, no chemical was isolated which shared the effects of the whole flavonoid extract (Viola et al. 1994).

Tilia cordata is a deciduous tree to 30m tall, with a large, spreading crown; young twigs glabrous or subglabrous. Leaves alternate, palmately veined, 3-9cm long, suborbicular, abruptly acuminate, acutely and finely serrate or denticulate, distichous, petiolate, cordate at base, glabrous except for some tufts of reddish-brown hairs in the vein-like axils beneath, tertiary veins not prominent; stipules caducous. Inflorescence axillary cyme-like clusters, obliquely erect, with 4-15 fragrant, white or cream coloured flowers; long peduncle adnate in basal half to the middle of a large, narrow, elongate, short-petioled foliaceous membranaceous bract; flowers perfect, 5-merous; sepals separate to the base, valvate in bud; petals usually present and conspicuous; stamens up to 80, free or in 5 antepetalous fascicles, one in front of each petal; epipetalous staminodes sometimes present. Ovary tomentose, 5-locular; stigma 5-lobed; style 1, dilated into a shallowly-lobed stigma; anthers 2-celled, opening longitudinally or by terminal pores. Fruit a unilocular nut, c.6mm, globose, tomentose, indehiscent, 1-3-seeded; pericarp of seed membranous, smooth or slightly ribbed. Fl. May-Jun.

Rich temperate woodland, throughout Europe except extreme north, extreme south, and some islands (Gleason 1952; Tutin et al. ed. 1964-1980); frequently cultivated in temperate zones worldwide, often lining streets.

TILLANDSIA

(Bromeliaceae)

Tillandsia mooreana *L.B. Smith* **(T. inflata** *Mez***)** – waráruwi, hichikoni, mescalito

Tillandsia purpurea *Ruiz et Pav.* **(T. azurea** *Presl***; T. longebracteata** *Meyen***; T. straminea** *Humb., Bonpl. et Kunth.***; Anoplophytum longebracteatum** *Beer***; Platystachys purpurea** *(Ruiz et Pav.) Beer***)**

Tillandsia usneoides *(L.) L.* **(Dendropogon usneoides** *(L.) Raf.***; Renealmia usneoides** *L.***)** – Florida Spanish moss, long moss, hanging moss, black moss, long-beard, tree-beard, vegetable hair

Tillandsia spp. – living air plants, tencho, soluchil

T. mooreana is regarded by the Tarahumara of Mexico as a companion to peyote [see **Lophophora**], and it is considered dangerous to damage the plant. Native informants have refused to divulge the importance of this bromeliad (Bye 1979b). It should be noted that to the Tarahumara, as with many other shamanic cultures, it is considered dangerous to harvest any sacred plant without the proper attending songs and ritual dedications for that plant, lest the plant spirit seek to harm the perpetrator of the desecration. The Tarahumara use a tea of T. benthamiana ['dowáka'] as an emetic purgative, and T. karwinskyana ['rereshiwasa'] to treat constipation. Tillandsia spp. are also applied as a body wash to treat rheumatism (Salmón 1995).

Interestingly, T. mooreana and T. recurvata are sometimes known in Sonora [Mexico] as 'mescalito', as is another bromeliad, a Hechtia sp. (Gentry 1942), though it was not made clear by Gentry where this naming originated from. This name has been associated with peyote by western drug-users (Trout & Friends 1999), yet is not known as properly being an indigenous term for peyote [outside of the fiction of Carlos Castaneda]. This reference, however, predates known use of the word in this context. Here it might simply mean 'little mescal', in reference to the superficial resemblance to Agave spp. [see *Methods of Ingestion*] (Trout pers. comm.).

T. purpurea and other Tillandsia spp. are depicted on pre-Incan Mochica pottery from northern Peru, in a context suggestive of possible psychoactivity. In Brazil, T. usneoides is used as an analgesic (Arslanian et al. 1986; Ott 1993). In other parts of South America, an unidentified Tillandsia sp. known as 'siempreviva' ['ever-living'] is sometimes added to San Pedro preparations [see **Trichocereus**] (Rätsch 1998).

T. purpurea has yielded many flavonoids, including retusin [5-OH-3,7,3',4'-tetramethoxyflavone; see **Ariocarpus**], artemetin [5-OH-3,6,7,3',4'-pentamethoxyflavone], possibly penduletin 4'-O-methyl ether [5-OH-3,6,7,4'-tetramethoxyflavone] and several other unisolated methoxylated 5-OH-flavones (Arslanian et al. 1986).

T. recurvata has yielded the unusual cycloartane triterpenes 25-hydroperoxycycloart-23-en-3β-ol and 24-hydroperoxycycloart-25-en-3β-ol [which decompose when the plant is dried], as well as cycloartanone, 24-methylenecycloartanone, cycloartenone, cycloartanol, 24-methylenecycloartanol, cycloartenol, lanostenol, lanosterol and 24-ethylcholest-4-en-3-one. All were found only in trace amounts (Cabrera & Seldes 1995).

T. usneoides has yielded the flavonoid 3,6,3',5'-tetramethoxy-5,7,4'-trihydroxyflavone; sterols such as β-sitosterol, cycloartenone, cycloartenol, cycloart-23-ene-3-β,25-diol, cycloart-25-ene-3-β,24-diol, 25-MeO-cycloart-23-ene-3-β-ol, 3-β-OH-cycloart-25-ene-24-one, cycloeucalenol and 24-methylenecycloartenol; and triterpenes [friedelin and 2 unidentified cycloartane triterpenes] (Atallah & Nicholas 1971; Lewis & Mabry 1977).

Raphides [bundles of tiny needle-like crystals of calcium oxalate] and proteolytic enzymes are present in the genus; raphides act as irritants, and their action is thought to be strengthened by the enzymes [see also **Spathiphyllum**] (Benzing 1980; Frohne & Pfänder 1983).

Tillandsia mooreana is an erect epiphyte, to c.1m tall when flowering. Leaves green, very numerous, simple, basal, spirally arranged forming a large cluster, blades flat, narrowly triangular, caudate-attenuate, 4cm wide, to 55cm long, densely and minutely pale-appressed-lepidote, sheathing below; sheaths elliptic, large, indistinct. Scape robust, erect or ascending, to 20cm long, glabrous; scape bracts foliaceous, spreading or reflexed-spreading, linear-lanceolate, filiform caudate, to 20cm long, many times as long as internodes, 25mm wide, coarsely pale-pruinose-lepidote towards apex. Inflorescence a terminal, bipinnate, paniculate spike 40-100cm long, 25cm diam.; primary bracts like the scape-bracts, the lower ones exceeding the axillary spikes, the upper shorter; spikes erect or divergent, oblong, 10-20cm long, 35-45mm wide, 14-20[or more]-flowered, rhachis straight, glabrous; floral bracts recurved-spreading and exposing the sepals and rhachis, 3-4 times as long as internodes, suborbicular, mucronulate, 3cm long, equalling or exceeding sepals, inflated, ecarinate, glaucous outside, lepidote inside, bright pink, finely nerved, fleshy-coriaceous, finely verrucose; flowers subsessile, divergent; sepals broadly elliptic, acute, 25-30mm long, ecarinate, subcoriaceous, even or nerved, glabrous, evenly connate for 3mm, dorsal side glabrous, smooth; calyx purple, tubular, exserted from bracts, petals purple, 4cm long, the claw linear, the blade elliptic, obtuse, narrowly white-margined; stamens and pistil exserted, stamens 6 in 2 series. Ovary superior, glabrous, 3-celled, placentation axillary; ovules numerous, caudate; style 3-parted. Fruit a septi-

cidal capsule; seeds erect, narrowly cylindric or fusiform, the plumose appendage basal, straight, white. Fl. Oct.

Shady side of cliffs in oak and 'short-tree' forest, epiphytic on Quercus albocincta or in rock of cliff-faces, from 600-1800m; w. slopes of Sierra Charuco and Sierra Saguaribo, Rio Mayo, Sonora, Jalisco, Guerrero, Oaxaca [Mexico] (Gentry 1942; Mez 1935; Shreve & Wiggins 1964; Smith & Downs 1977).

Two other, different, species have been known as T. inflata – T. inflata *(Wawra) Baker* [now known as Vriesea inflata *(Wawra) Wawra*], and T. inflata *Baker* [now known as V. heterostachys *(Baker) L.B. Smith*] (Smith & Downs 1977).

Many Tillandsia spp. absorb moisture through their highly-developed trichomes, or peltate scales, which cover the leaves; others collect water in the leaf-axils. After flowering, the mother-plant often gradually dies off, and produces offshoots which can be further propagated when larger, or left to form clumps over time. Some species do not produce offshoots, but instead produce copious seed. Tillandsia spp. require ample light, air circulation, and humidity to flower; to develop larger plants, flowering should be avoided if possible. In any case, the plants require fairly good access to light, especially indoors. Many species simply need a good anchor for their roots, and do not need to be planted in soil; large paddings of sphagnum moss should be avoided as a base, as it will encourage rot if kept damp. Drought-hardy. If natural humidity can not be simulated, submerge plants in water with a small amount of fertiliser, for several hours every couple of weeks. Additional misting can also be advantageous. Fertiliser should contain ammoniacal or nitrate nitrogen, phosphorous and potassium [2:1:3]; prefers water pH of 6 (Isley 1987).

TRACHELOSPERMUM

(Apocynaceae)

Trachelospermum asiaticum *(Sieb. et Zucc.) Nakai* **(T. asiaticum var. brevisepalum** *(C.K. Schneid.) Tsiang***; T. divaricatum var. brevisepalum** *C.K. Schneid.***; T. foetidum** *(Matsum. et Nakai) Nakai***; T. gracilipes** *Hook. f.***; T. jasminoides ssp. foetidum** *Matsum. et Nakai***; T. lanyuense** *C.E. Chang***; T. siamense** *Craib***; Malouetia asiatica** *Sieb. et Zucc.***; Melodinus cavaleriei** *H. Lév.***)** – luo shi teng, teikakazura

Trachelospermum jasminoides *(Lindl.) Lem.* **(T. adnascens** *Hance***; T. divaricatum** *Thunb.***; Rhynchospermum jasminoides** *Lindl.***)** – Chinese star jasmine, star jasmine, confederate jasmine, luo shi teng

The dried, leafy stem of 'luo shi teng' [usually T. jasminoides, or T. asiaticum] is used in TCM in a dose of 5-10g, to relax rigid muscles, stop bleeding, and restore the normal flow of vital energy. It also acts as a tonic, analgesic and emmenagogue (Huang 1993; Keys 1976). The plant is used in Indian and Pakistani folk medicine to treat rheumatism, wounds, gonorrhoea, sciatica, carcinomas and viper bites; the seeds have haemostatic and cardiotonic properties (Rahman et al. 1987). In India, T. fragrans ['dudhi'] is used as a substitute for 'dita', **Alstonia** scholaris (Nadkarni 1976).

Bioassays of a crude T. asiaticum [leaves and stems] extract, which was obtained in low yield, showed mild empathogenic or stimulant activity. At the dose that filled one 'vegicap', the extract showed empathogenic activity similar to low-dose *ibogaine*. Variation existed between different batches, with some appearing inactive, and others becoming so after a few days, possibly due to the auto-oxidation that is common in iboga alkaloids (theobromus pers. comm.). An extract of T. jasminoides [dose not stated] produced effects which were described as "quite psychedelic", but also "awful" – disturbing fluctuations in blood pressure were noted, as well as disturbed vision and moments of unconsciousness. Several days were required before the psychonaut felt normal again. Smaller doses of the same extract had a mild and pleasant effect (Torsten pers. comm.).

T. asiaticum leaves and stems have yielded pregnane glycosides, including teikaside A [0.002%] as a major component, as well as lignans (Abe & Yamauchi 1981). T. asiaticum var. intermedium stems have yielded *scopoletin*, vanillic acid, and the lignans arctigenin, matairesinol, trachelogenin, nortrachelogenin and (2R,3R)2-4"-OH-3"-MeO-benzyl-3-3',4',5'-trimethoxybenzyl-butyrolactone (Nishibe et al. 1981). Neither of these plants seems to have been analysed for alkaloids, though they potentially contain alkaloids similar to those found in T. jasminoides.

T. jasminoides has been found to yield several indole alkaloids [0.09% from leaves and stems], consisting of *ibogaine*, tabernaemontanine, *vobasine* and *voacangine*-7-OH-indolenine (Rahman et al. 1988); another study found instead *coronaridine*, *voacangine*, apparicine, conoflorine and 19-epi-voacangarine [see also **Tabernaemontana**, **Voacanga**] (Rahman et al. 1987). The herb has also yielded glycosides and other compounds – arctiin, dambonitol, tracheloside, nortracheloside, matairesinoside, matairesinol-4,4'-di-O-β-D-glucopyranoside, nortrachelogenin-4,4'-di-O-β-D-glucopyranoside and arctigenin-4'-β-gentiobioside (Buckingham et al. ed. 1994; Huang 1993; Nishibe et al. 1971b).

Trachelospermum jasminoides is an evergreen climber to 7m, with milky sap; shoots slender, hairy when young, becoming glabrous. Leaves opposite, entire, margin +- recurved, leathery, markedly veined, 4-7.5 x 1.25-2.5cm, oval-lanceolate, tapered at both ends, dark shiny green, lighter beneath and downy at first, apex acute mucronate, to +- acute, occasionally indented; petiole 3mm long. Flowers fragrant, white, in glabrous axillary and terminal cymes; calyx 5-lobed, lobes lanceolate, reflexed; corolla with cylindrical tube 0.75-1cm, and 5 spreading twisted lobes overlapping to the right, c.2.5cm across limb, lobes narrow, wavy; stamens short, included; anthers united and attached to stigma; ovary of 2 carpels. Fruit a pair of terete follicles to 15cm; seeds comose. Fl. summer.

Native to China; used in horticulture as an ornamental climber, of which there are several varieties -

var. japonicum – leaves veined white, turning bronze in autumn

var. minimum – dwarf plant, leaves mottled

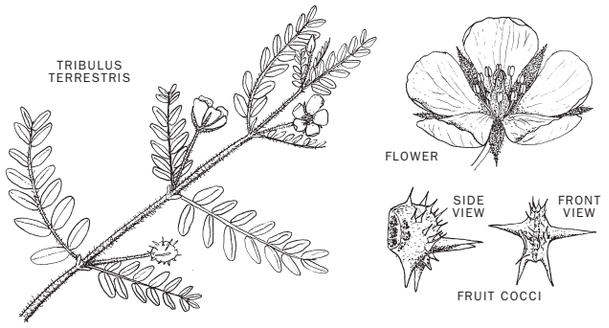
var. variegatum – leaves ovate to almost linear-lanceolate, with white and milk-green stripes, often tinged pink to red-bronze

var. wilsonii – leaves ovate to linear-lanceolate, veins distinct, flushed red-bronze to maroon in winter.

Propagate by seed, layering or semi-ripe cuttings in summer; grow in well-drained, moderately retentive soil in sun or with dry part shade; water moderately, maintain good ventilation. Tolerates winter min. of 5-7°C; should be grown in a conservatory in cold climates (Burras ed. 1994). Personally, I have found T. jasminoides [what is probably var. wilsonii] to tolerate winter temperatures at or below 0°C overnight for numerous nights in a row, though it may not fare as well with harsher extended frosts (pers. obs.).

TRIBULUS

(Zygophyllaceae)



Tribulus terrestris *L.* – caltrop, cathead, goat's head, yellow vine, California puncture vine, bear medicine, bear tobacco, ji li zi, ji li dze, ci ji li, gokshura, trikantah, shvadamstra, zama, chota gokhru, hommos el-harib, hasak, sa'adan, tadjnouft

Tribulus spp. – caltrop

The dried fruits of T. terrestris are used medicinally in scattered areas of the world. The plant is known to cause poisoning in sheep and cattle when feeding on it for long periods [as well as causing mechanical injury from the spiky fruit], with symptoms including CNS-derangement, jaundice, weakness of hind-limbs, photosensitisation and liver damage. Sometimes sudden death occurs from nitrate poisoning when the young plant is grazed (Bourke 1984; Gardner & Bennetts 1956; Lamp & Collet 1989; McBarron 1983). The hind-limb weakness has also been observed in sheep poisonings resulting from ingestion of T. micrococcus (Bourke & MacFarlane 1985).

In TCM, the fruit of T. terrestris is considered to have bitter, acrid and slightly cold properties, with an affinity for the lungs, spleen, liver and kidneys. Decocted in doses of 5-12g, it is a tonic, nutrient, antispasmodic, diuretic, slight hypotensive, galactagogue, blood-purifier and uterotonic. It strengthens bone and sinew, promotes semen production and improves vision, as well as treating vertigo (Huang 1993; Keys 1976; Reid 1995; Tierra 1988). In Ayurvedic medicine, its CNS properties are more recognised. A milk decoction of the fruit or aerial parts is known to be aphrodisiac. The fruit is also regarded as nervine, rejuvenative, tonic and analgesic, and is used to treat urinary tract disorders, gout, rheumatism, cough and infertility (Chopra et al. 1958; Frawley & Lad 1986; Nadkarni 1976). In Iraq, T. longipetalus [T. alatus] is used for the same purposes as T. terrestris (Chakravarty 1976).

In Ladakh, India, T. terrestris fruits and young twigs are dried, powdered, then roasted and dissolved in milk. This infusion is aged for 3-4 days to form a preparation known as 'zimpating', which is drunk after meals, and causes 'delirious' conditions when taken in excess. In the same area, the fruits are used in the manufacture of the local barley-based beer [Hordeum vulgare], 'chhang' [see *Methods of Ingestion*], also containing Delphinium cashmerianum roots [see *Endnotes*] and **Artemisia** tournefortiana twigs, as well as wheat flour (Navchoo & Buth 1990).

In India, T. terrestris fruits have also been used mixed in equal parts

with **Mucuna** pruriens seeds as an aphrodisiac, taken as a dose of c.1.8g with sugar and tepid milk (Dutt 1989; Nadkarni 1976). Given in higher doses, this combination could possibly act as a kind of ayahuasca analogue [see *Methods of Ingestion*], due to the potential MAOI effects of T. terrestris. However, high levels of *L-DOPA* from **Mucuna** could perhaps prove dangerous with MAO-inhibition (pers. obs.).

The powdered, dried fruit or seed of T. terrestris [15-17g] and a commercial powdered extract [concentrations of 1:5 and 1:10] equivalent to that amount have been successfully used as an MAOI in ayahuasca analogues by some people (friendly pers. comm.; Raver pers. comm.; pers. comms.), although others have found no apparent MAOI activity with this herb (Trout pers. comm.; pers. comms.). One of these combinations [with **Evodia** rutaecarpa unripe fruit extract – see **Evodia** for further discussion] could not accurately be described as an ayahuasca analogue for its effects, although definitely psychoactive. Attempts at combining the same T. terrestris extract with other *tryptamine*-containing plants resulted in no apparent MAOI activity (friendly pers. comm.). Another bioassay with a low-alkaloid extract of a **Desmanthus** sp. found T. terrestris to be seemingly effective as an MAOI, though the total effects were mild and inconclusive (Raver pers. comm.). Following reports of synergy and potentiation between **Psilocybe** mushrooms and **Peganum** harmala seeds, I combined an extract of T. terrestris fruit [calculated to chemically approximate several grams of P. harmala] with a mild dose of mushrooms of known potency, yet no extra psychotropic contribution was noted from this addition of T. terrestris (pers. obs.). The extract of T. terrestris most commonly used [and that used by myself previously] is prepared from material of Indian origin, though Chinese material has been used more commonly as the whole dried fruit. In either form it has been observed to be psychoactive on its own, similar to the effects of **Peganum** harmala but milder, and without gastric upset. One person used 30g of Chinese material for these effects – a decoction drunk over the course of a day resulted in "a definite mood lifting similar to chewing caapi" [see **Banisteriopsis**]. Anecdotal reports suggest that T. terrestris root bark is also psychoactive (friendly pers. comm.; Raver pers. comm.; Reville pers. comm.). It seems that T. terrestris is highly variable in chemical content and individual responses to its consumption, and that it is not a reliable MAOI, unless at some point the potent strains are isolated and put into circulation. Any MAOI activity observed from some batches might possibly be due to non-alkaloidal components of the herb (pers. obs.). Some people suspect the herb may be toxic with any regular consumption (Trout pers. comm.), which remains to be seen. As always, however, caution is advised, despite the seeming innocuity of this herb.

In Afghanistan, T. terrestris is also used as a spasmolytic and diuretic (Ott 1993). The Navajo smoke T. terrestris [usually the roots], 'bear medicine', as part of their smoking mixtures for performing the Bear Chant ritual (Winter 1998). In n. Queensland, Australia, T. cistoides is used by some indigenous people of the Pennefather River area to treat toothache, by keeping a portion of the plant between the gums and cheek (Cribb & Cribb 1981; Lassak & McCarthy 1990); it has been reported to be toxic, presumably to livestock (Gardner & Bennetts 1956).

T. cistoides whole plant from the US tested alkaloid-positive (Fong et al. 1972). Aerial parts have yielded *GABA* (Durand et al. 1962), steroid saponins including the cardioactive cistocardin, as well as 5'-(hydroxysulphonyloxy)-jasmonic acid, D-(+)-pinitol, sucrose and N-acyl-*tyramine*s (Achenbach et al. 1994); leaves have also yielded cardioactive saponins, as have the roots, which also yielded tribulosin, cholestane glycosides, D-(+)-pinitol and sucrose (Achenbach et al. 1996).

T. terrestris has been analysed for alkaloids numerous times. Fruits from Israeli plants tested weakly to strongly positive for the presence of alkaloids in several tests (Fong et al. 1972). Whole plant material from Toowoomba [Qld, Australia; harv. Nov.] tested weakly positive for alkaloids (Webb 1949); aerial parts have yielded from 0.001-0.0044% alkaloids, which in one Australian sample [mature parts collected in midsummer] 91% consisted of a mixture of *harman* and *norharman* (Bourke et al. 1992a; Chopra et al. 1958). One analysis of seeds [probably whole fruits] detected *harman* and *harmine* (Lutomski et al. 1968a); another detected traces of *harmine*, and no *harman* (Lutomski & Nowicka 1969). One analysis detected *harmol* and *harman* in unspecified parts (Gill & Raszeja 1971); another found *harman*, *harmine*, *harmaline* and *harmalol* (Tosun et al. 1995), and *leptaflorine* has also reportedly been found (Shulgin & Shulgin 1997). The plant has tentatively tested positive for the presence of traces of *5-methoxy-DMT* (Trout ed. 1997d). Fruits have also yielded lignanamides derived from *tyramine* [all showed some cytoprotective activity] – N-trans-feruloyltyramine, N-trans-coumaroyltyramine, tribulusamides A & B, and terrestriamide; as well as β-sitosterol (Li et al. 1998). Aerial parts and fruits also yielded 2.8% steroid saponins, including terrestroside F, *diosgenin* glycosides, tigogenine glycosides, tribuloside, dioscine, graciline, protodioscone, tribulosine, desoxydiosgenin, ruscogenin, chlorogenin, gitogenin, tigogenin, neotigogenin, hecogenin, neohecogenin, spirosta-2,5-diene, hecogenone, 25R-spirostan-4-ene-3,12-dione, (5-α,25R)-spirostan-3,6,12-trione and 25R-spirostan-4-ene-3,6,12-trione; flavonoids, such as astragalin [kaempferol-3-glucoside] (Buckingham et al. ed. 1994; Festi & Samorini 1997; Huang 1993; Iskenderov 1971; Kintya et al. 1973; Rastogi & Mehrotra ed. 1990-1993; Tomowa et al. 1974; Wu, G. et al. 1996; Xu et al. 1998; Yan et al. 1996), kaempferol-3-rutinoside, kaempferol [MAOI (Sloley et al. 2000)], quercetin, isorhamnetin [MAOI (Sloley et al. 2000)] and rutin; as well as potassium nitrate, linoleic acid, behenic acid, ascorbic acid, phylloerythrin, peroxidase, phlobaphenes, 0.4% oxalates, essential oil and tannin. The whole plant tested positive for HCN (Buckingham et al. ed. 1994; Festi & Samorini 1997; Rastogi & Mehrotra ed. 1990-1993; Reid 1995; Tierra 1998; Watt & Breyer-Brandwijk 1962; Zafar & Nasa 1988).

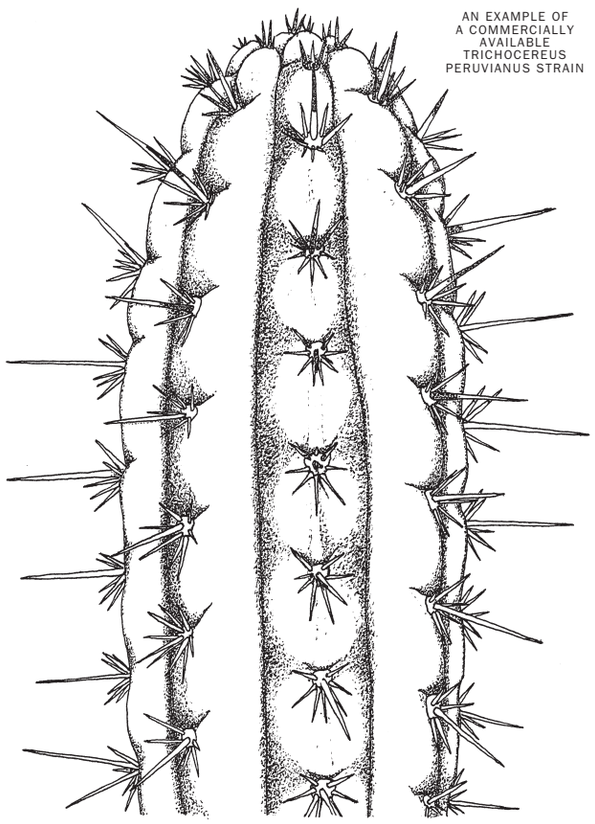
Tribulus terrestris is an annual herb, growing profusely after summer rains; extremely variable in habit, with spreading prostrate branches up to 2m long, +- pubescent, sometimes hairless, sometimes woody at the base. Leaves unequal, the larger up to 6cm long, usually much smaller, with up to 8 pairs of leaflets; the smaller up to 3.5cm long, usually much less, with up to 6 pairs of leaflets; leaflets 4-15 x 1.5-7mm, rather oblique, oblong to ovate-lanceolate, apex acute or subobtuse, hairy on both surfaces or nearly hairless; stipules up to 10mm long, linear or linear-lanceolate, acute. Peduncle usually shorter than, or as long as, subtending leaf; sepals c.3.6mm long, linear-lanceolate, usually hairy outside; petals 5, light-yellow, 3-8(-12)mm long, broadly cuneate, usually shorter than sepals; filaments c.3mm long; anthers 0.5-1(-2)mm long. Ovary with stiff, bulbous-based hairs; style very short; stigma 0.8-1.2mm long, hemispheric, mostly assymetrical and nearly sessile on ovary. Fruit breaking up into 5 cocci, each with 2 strong divergent spikes in the upper and 2 smaller ones in the lower part, usually crested on the back (Exell et al. ed. 1960-1993).

Widespread. Noxious weed in Australia [Vic., SA & NSW].

In Australia, T. terrestris occurs as a complex containing four different taxa, T. terrestris 'long-style' [style 0.6-1.3mm long, cocci not dorsally rounded, cocci spines long median], T. terrestris 'short style' [style 0-0.3mm, cocci not dorsally rounded, cocci spines long median], T. micrococcus [style 0.7-1.4mm, cocci dorsally rounded, cocci spines median, lacking or short] and T. minutus [style 0.2-0.7mm, cocci dorsally rounded, cocci spines median, lacking or short] (Barker 1998).

TRICHOCEREUS

(Cactaceae)



Trichocereus atacamensis *(Philippi) Marsh.* **(Cereus atacamensis** *Phil.***; Echinopsis atacamensis** *(Phil.) Friedrich et Rowley***; Helianthocereus atacamensis** *(Phil.) Backeberg***)**

[Note: most, if not all Trichocereus spp. are now classified under Echinopsis spp. – see discussion below]

'San Pedro' [T. pachanoi] is widely used traditionally in areas of Peru [a practice dating back to at least c.1000BC], where it is consumed by 'maestros' [shamans]. Usually, it is consumed by both the shaman and the patient in all-night healing sessions, whereby the shaman divines the nature and cause of the illness or spiritual-affliction, and which herbs to prescribe. However, in these circumstances, often the dose administered is insufficient for notable visionary activity. Shamans also take the cactus as a solitary practice, in larger doses, to learn. Wild plants are considered more potent than cultivated ones; the strength of cultivated plants is considered to be increased by planting near sacred ruins. The cactus is harvested with a brand-new knife, at a time favourable according to moon phases; the person harvesting the plant must have kept a diet [no onion, garlic, chilli (**Capsicum** anuum), salt, pork fat or blood] and abstained from sex, as well as observing rituals with offerings for harvest. Rituals are usually held on Tuesday or Friday nights, sunset to midnight, as these are considered the most efficacious times for shamanic work. A piece of the cactus [dosage being adjusted to suit the patient's size and the characteristics of their illness] is sliced and boiled for several hours in a tin of water, and the concentrated liquid drunk. Some may also add **Brugmansia** arborea ['misha'] and other **Brugmansia** spp. in careful amounts [a practice considered dangerous], **Lycopodium** spp. ['condorillo', 'condor misha'], a **Tillandsia** sp. ['siempreviva'], **Valeriana** adscendens ['hornamo morado'] and many other potential 'magical' additives. Emetic herbs are usually also given after these additives are used. Some also consume a liquid tobacco preparation [see **Nicotiana**] by pouring it into the nostrils, before and during the ceremony. The shaman is usually consulted at his 'mesa' [table, or more specifically in this case, altar], which may consist of an array of ritually-powerful objects laid out in meaningful positions on a mat or small altar before the shaman. In northern highland areas, the tip of the cactus is often a central object on the mesa, acting as a "cosmic tree" and considered the most powerful part of the plant [though maybe not pharmacologically – see below]. Singing, whistling, prayer, and use of rattles and percussion may often accompany some stages of the ritual; it is often forbidden to see lights for several hours after consumption. More problematic cases are treated around certain high-altitude lakes, where the most efficient medicinal herbs may be gathered and where spirit forces are strongest; the long pilgrimage to the lakes also involves ritual bathing in the waters, for the purpose of spiritual rebirth or cleansing. The ritual is closed with the shaman blowing 'arranque' [see **Citrus**] over everyone, and giving each person some to drink to terminate the effects. The day after the ceremony, the same diet must be kept, and bathing, alcohol and seeing fire are prohibited (Davis 1983; De Feo 2003; De Rios 1968, 1977; Joralemon 1984; Ostolaza 1984; Polia & Baranchi 1991; Sharon 2001; Trout & Friends 1999).

T. pachanoi has been claimed to have been an ingredient of a drink called 'cimora' [thought to be once consumed around Huancabamba], which was also said to contain Neoraimondia macrostibas, a Pedilanthus sp. ['cimora misha'; see *Endnotes*], **Isotoma** longiflora, **Datura** stramonium and other plants. However, it is now thought that such a mixture may never have existed under that name, and that the term 'cimora' refers to a number of different plants [particularly **Brugmansia** spp.] which are sometimes considered to have malevolent properties. One native informant reported that cimora "is a conceptual term referring to 'algo malo' – something bad" (Davis 1983; Schultes 1967a). Nevertheless, these plants [with the exception of Neoraimondia macrostibas] and many others were reported by Rätsch (1998) to be used as additives to San Pedro brews in Peru [see also *Endnotes* for some of these].

T. peruvianus is believed to have been used as a visionary plant [as well as T. pachanoi] in Peru since ancient times, and is still used in the same manner as T. pachanoi. Both [though usually one or the other] have been depicted in motifs and figurines decorating ceramics from both Incan and pre-Incan cultures including the Cupisnique, Moche, Paracas, Wari, Chimú, Chavín and Nazca (De Feo 2003; Ostolaza 1995, 1996, 1997, 1998, 1999). In many areas of Peru, T. pachanoi is planted near the entrance to the house, as it is believed to act as a 'supernatural guardian', scaring away intruders with unearthly cries (Rosa 1999). T. bridgesii is also known in Peru to have psychoactive properties, and may have had a history of use in Bolivia (Davis 1996; Rätsch 1998), where it is known to cause 'drunkenness'. Although some modern-day Bolivians near La Paz do use this species as a shamanic ally, signs of traditional use have so far been elusive (Kavlin, in White 2000).

A bioassay of a very small amount of the outer skin from a single rib of Chilean T. atacamensis [c.15-20cm long section] produced strong stimulation (pers. comm.). Spines of this species have been found in prehistoric sites in the Atacama desert [n.e. Chile] in connection with psychoactive snuff-powders [**Anadenanthera** peregrina], possibly having been used to clean the snuffing tubes. In Peru, archaeological remains indicate that the Chavin culture there [1000-300BC] also used T. pachanoi as well as A. peregrina. T. pasacana has been found in Argentinian earth-layers dating back to 7670-6980 BC; later, these finds occur together with 'coca' leaf [see **Erythroxylum**], and in the same area today, the fruits [minus the seeds] and flowers are used to make alkaline ash for use with coca. The Mataco use the flesh of T. terscheckii and T. poco for this purpose, and they are said to improve the flavour and increase the strength of the coca. Taken alone, T. terscheckii is said to be equal in effect to T. pachanoi, though some strains are apparently inactive [see below]. Also, in n.w. Peru, the rare T. peruvianus var. truxilloensis is cultivated with 'trujillo coca' [**Erythroxylum** novogranatense var. truxillense] to shelter the latter plants (Rätsch 1998; Torres 1993, 1995). T. cuzcoensis has been depicted on some Mochica pottery, often in the context of hunting or battle. The Incas were reported to have eaten the cooked flowers. Its fruits are edible, and a substance obtained from them called 'nopal gum' is used in Cuzco as "a mucilaginous additive to whitewash". The Incas also used cacti, such as T. cuzcoensis, in strengthening the walls of dwell-

ings, due to the strong vascular bundles of the stems. T. peruvianus was also proposed to have been so used (Ostolaza 1995, 1998, 2000; Towle 1961). In Peru, the sap of T. cuzcoensis is used to treat 'cancerous lesions', and in Chile unspecified parts of T. chiloensis are used against tumours (Hartwell 1968).

In n. Argentina, fishermen and other folk sometimes consume a stew of [what was reported to be] T. pasacana as a recreational inebriant. Bioassays using young, seed-grown plants [a single plant several inches in diameter, for a dose] revealed definite psychoactivity, though insufficient material has prevented experiments with larger doses, or older plants. The effects were subjectively deemed to have some *mescaline*-like qualities, though another psychoactive component predominated. The inebriation was described as being on the threshold of a visionary or psychedelic experience (Thompson pers. comm.). Others have described stimulant activity from ingesting T. pasacana (Trout ed. 1999). To confuse the matter, Thompson regards T. terscheckii as a low-altitude variety of T. pasacana [a synonymy strongly disputed by others], and as such the plants reported by him to be consumed in Argentina may have been T. terscheckii. The bioassays mentioned above were conducted using plants that were more typical of T. pasacana. Most specimens of the two species are quite distinct from one another macroscopically, though they are known to interbreed, producing offspring which are less easily identified. Perpetuating the confusion, some specimens of T. terscheckii and T. pasacana in the Huntington Botanic Gardens [California] are clearly mislabelled (pers. obs.). It has been reported that "men and animals on the deserts of Argentina's Northwest in time of drought may find relief by drinking the juice of the crushed plant" of T. terscheckii, aparently without intoxication (Reti & Castrillon 1951), yet this might perhaps also be a confusion with another similar species.

In the last few decades, T. pachanoi [and rarely other Trichocereus spp., such as T. bridgesii, T. macrogonus and T. peruvianus; see below under the chemical listings for lesser-used species] have been used as psychoptics by western experimenters and others, usually unrelated to traditional use. In fact, T. scopulicola appears to have been used by many for quite some time, in the belief that it was T. pachanoi! These two species are so superficially similar [complicated by the near unavailability of published descriptions of T. scopulicola], and of similar potency and chemical content, that the differences were only noticed recently, at least amongst psychonauts who have been prepared to discuss their experiments. The general dosage for fresh T. pachanoi or T. scopulicola may be a piece of the branch c.30-40 x 7-10cm [or c.0.8-1kg w/w], though sometimes up to 60cm of length may be required.

The best time to harvest *mescaline*-containing species [for highest potency] is considered to be during summer and autumn. Some people prefer to deprive the plant of water for up to 2 months before harvest. These cacti become more potent with age. Older growth is more potent than growing tips, but very old, woody growth is usually not very potent at all (pers. comms.). It has recently been established through numerous bioassays that the flowers are psychoactive, and surprisingly, more potent than the branches of active Trichocereus spp. This is most likely due to a high alkaloid concentration in the green fleshy parts of the flower calyx (Trout pers. comm. 2004). Regarding traditional knowledge of potency and effects, in n.e. Peru a variegated form of San Pedro with white and red flowers, known as 'San Pedro misha', is said to be particularly strong. Plants growing on rocks are also regarded as more potent compared to those growing in soil, and specimens in arid zones are more potent than those in humid zones. A specimen growing near fire is thought to have no potency. Regarding the number of ribs, 12-ribbed plants are used for divination; 4-7-ribbed plants for curing; and 5-ribbed plants for 'protection rites' (De Feo 2003).

To harvest, the branch should be cut [with a very sharp, clean blade] in dry weather at a slight angle so that water will not accumulate in the wound, which will be cup-like in the centre when healed. The cutting should be cleaned of spider webs and other matter with a small brush. Some prefer to let it sit for a month or more to lose some water, to reduce the end volume to be consumed. The spines may be removed with a sharp knife, by cutting them away at the base with a small v-shaped notch of flesh. This is not necessary unless on stoutly-spined species, if intending to strain the brew by hand, or if your straining material will allow fragments to pass through. Freezing the cactus prior to preparation will break down cell walls and aid in efficient extraction once thawed. The cactus is chopped finely or sliced, and most people boil it gently in water [preferably acidified with lemon or lime juice] for several hours, with frequent stirring, and removal of surface scum. Often the pulp is then strained out, and the extract concentrated with gentle heating to minimise volume. Some prefer to only use the inner layer of flesh just under the skin, as this portion has the highest concentration of *mescaline* [the core and surrounding flesh contain much less, but can still be used]. This can be dried, powdered, and encapsulated for ingestion, though a large amount of material is still needed. Sometimes the liquid extract is reduced to a gummy concentrate to be rolled into small pills and swallowed – this method may cause greater gastric distress on an empty stomach than liquid consumption. Of course, people are ingenious and many methods of consumption have been devised and put into practice.

A simple modification offered by K. Trout (Trout & Friends 1999) stems from two important observations – that prolonged heating and volume-concentration seem to enhance the nausea produced by the resulting brew, and that minimising the amount of water added is also desirable to reduce nausea. The [once-frozen] thawed cactus is chopped or blended, then mixed with lime juice [2-3 limes per kg of cactus] and put in a non-aluminium pot. Slowly it is brought to the boil with stirring, and [still stirring] simmered gently for another 20-30 minutes. It is cooled and strained roughly through a sieve, then again through a fine filter [without squeezing pulp]. The pulp is returned to the pot and the process repeated; a little water may be added only if necessary. The second time, it is strained finely and the pulp squeezed dry. The resulting brew is best drunk cold, and as quickly as possible.

Liquid cactus preparations are very bitter, often with an unpleasant 'snotty' texture, and many say they should be drunk over a period of an hour or so to lessen sudden gastric disturbance. In practice, stretching it out does not help, and may actually make it more difficult to consume the full dose. Nausea and physical discomfort usually occur in the first hour or two after consumption, if at all [some people never get sick], and vomiting often occurs shortly afterwards. After this, or after the 3-hour mark if it is still down, the nausea and most of the discomfort disappear and the psychoactive effects begin to fully manifest. Often the effects come on in waves, and the full peak may not be felt until about 3-4hrs or more after onset; the whole experience may last up to 12hrs or more, depending on dose, and [in the case of most T. pachanoi] is characteristic of the *mescaline* experience, being a 'classic' psychedelic with a vivid colour aspect, and strong CNS stimulation (pers. comms.; pers. obs.).

It was observed by Agurell (1969a) that Trichocereus spp. with stems that branch or form candelabras produce *mescaline*, and that columnar, creeping, or low species produce N-methylated *tyramines* and/or disubstituted *phenethylamines*. There are, however, many exceptions to this.

It should also be noted that many of the plants analysed by Agurell and associates were of cultivated, European origin (Agurell 1969a), and that many of the extraction methods used would not have recovered all *mescaline* present. It has been observed that active species with less internal slime produce less nausea (Trout & Friends 1999). All yields given below are from fresh material unless otherwise specified.

T. bridgesii was found to contain more than 0.05% alkaloids, mostly *mescaline*, with smaller amounts of *tyramine*, 3-MeO-*tyramine* and *DMPEA* (Agurell 1969a); analysis of dry material yielded 0.56% *mescaline* (Cjuno et al. 2007). The triterpenes bridgesigenins A and B were isolated, but much of the yield was probably formed as an artefact of the extraction process, through hydrolysis of unidentified glycosides (Kinoshita et al. 1992; pers. comm.). Bioassays show it to have similar potency to T. pachanoi (Davis 1983; pers. comm.), or even more potent. Other strains of this species, such as the 'Eusaporus' clone and the monstrose strain, T. bridgesii forma monstrosa [see below], have been found to be particularly potent (Trout ed. 1999; Trout & Friends 1999; pers. comms.).

T. candicans was found to contain more than 0.05% alkaloids, including N-methyl-*tyramine* [0.004% d/w], *tyramine*, *hordenine* [major compound] and candicine [4-OH-N,N,N-trimethyl-PEA], as well as 2 unidentified alkaloids in trace amounts (Agurell 1969a; Mata et al. 1976). Extracts of the plant induced secretion of *epinephrine* from the adrenal glands in animals (Lewis & Luduena 1934); stimulation of respiration and cardiac activity, hypertension, protrusion of the eyes, mydriasis and incoordination were observed in dogs; in toads, *nicotine*-like toxicity was observed (Luduena 1934).

'T. cordobensis' has not been chemically analysed. Specimens believed to represent this species [cultivated in e. Australia] have been found to be psychoactive similarly to T. pachanoi or T. scopulicola, though less potent (pers. comms.). Myself and others have been unable to find a source or author for this species name (pers. obs.; Trout pers. comm.).

T. cuzcoensis was found to contain more than 0.05% alkaloids, mostly 3-MeO-*tyramine*, with 1-10% each of *mescaline* and *tyramine*, and traces of 3-OH-4,5-dimethoxy-*phenethylamine* (Agurell et al. 1971); later analysis of specimens from 4 locations found no *mescaline* (Serrano 2008). Most human bioassays of this species [wild-harvested from near Cuzco, Peru] have been negative, but there is one positive report using the same material. Proper identification of this species is in dispute (Trout & Friends 1999).

T. fulvilanus was found to contain more than 0.05% alkaloids, mostly *tyramine* and N-methyl-*tyramine*, with traces of *mescaline* (Agurell et al. 1971). There is one report of a positive bioassay, but identification of the material might have been in error (Trout & Friends 1999).

T. grandiflorus seems to exist in at least 3 varieties – a white, nocturnally flowering type, which was claimed to be '*mescaline*-active' in a human bioassay; a red, day flowering type [sometimes referred to as Helianthocereus grandiflorus, as a separate variety] which seemed to contain *DMT* in preliminary analysis by A.T. Shulgin; and a yellow flowered type which did not contain *DMT*. There is the possibility that contaminated equipment gave a false-positive indication for the presence of *DMT*, and Shulgin himself doubts the validity of the results obtained (Shulgin

pers. comm.; Smith 2000). The taxonomical status of what is referred to as T. grandiflorus greatly needs clarification.

T. huanucoensis has produced strong stimulation in a human bioassay, but remains chemically unanalysed (Trout pers. comm.).

T. huascha was found to contain 0.001-0.01% alkaloids, over 50% of which was *hordenine* (Agurell 1969a).

T. knuthianus was found to contain 0.01-0.05% alkaloids, consisting of 10-50% each of *tyramine* and N-methyl-*tyramine* (Agurell et al. 1971).

T. lamprochlorus was found to contain 0.01-0.05% alkaloids, over 50% of which was *hordenine* (Agurell 1969a); others have found traces of candicine (Trout ed. 1999, citing Reti & Arnolt 1935. Actas y Trabajo del V. Congr. Nac. de Medicina, Rosario 3:39).

T. macrogonus was found to contain 0.01-0.05% alkaloids, mostly *mescaline*, with lesser amounts of *tyramine*, 3-MeO-*tyramine* and *DMPEA* (Agurell 1969a). Human bioassays so far have given mixed results – some have claimed high potency [2-2.5 times as potent as 'average' T. pachanoi], whilst others have found it to be less potent, or even inactive. Proper identification of this species is still disputed [see below], and some believe much of the material sold as T. peruvianus is actually T. macrogonus; sometimes the reverse may be true (Trout ed. 1999; Trout & Friends 1999; pers. comms.).

T. manguinii was found to contain 0.01-0.05% alkaloids, consisting of 10-50% each of *tyramine*, N-methyl-*tyramine* and *hordenine*, and 1-10% 3-MeO-*tyramine* (Agurell et al. 1971).

T. pachanoi has yielded 0.05-0.23% alkaloids, mostly *mescaline*, with lesser amounts of 3-MeO-*tyramine*, *DMPEA* [c. 5% of the amine fraction], and traces of *tyramine*, 3,5-dimethoxy-4-OH-*phenethylamine*, 3,4-dimethoxy-5-OH-*phenethylamine* and *anhalonidine* (Agurell 1969a, 1969b; Agurell & Lundstrom 1968; Lundstrom 1970); dry samples have yielded 0.09-2.4% *mescaline* (Cjuno et al. 2007; Crosby & McLaughlin 1973; Gennaro et al. 1996; Helmlin & Brenneisen 1992; Poisson 1961); Brown et al. (1968) found several alkaloids which they did not identify. Also found [in a plant cultivated in Japan] were triterpenes – pachanols A & B, and bridgesigenins A & B. Enzymatic degradation of the extract resulted in the formation of pachanols A & C, and bridgesigenins A & C (Kinoshita et al. 1995). For mention of the possible artificial origin of the triterpenes [which may nonetheless occur naturally in much smaller amounts], see the T. bridgesii entry above.

T. pallarensis was psychoactive and indicated to contain *mescaline* from human bioassays; it was claimed to be superior to T. pachanoi in potency (Trout & Friends 1999).

T. pasacana yielded 0.08% candicine, *tyramine*, N-methyl-*tyramine* and *hordenine* (Agurell 1969a; Meyer & McLaughlin 1980). It is very similar to T. atacamensis [which is sometimes considered a variety of T. pasacana, and has not been chemically analysed].

T. peruvianus was found to contain 0.001-0.01% alkaloids, mostly *tyramine*, and traces of 3-MeO-*tyramine*, with no *mescaline* detected (Agurell 1969a); others have obtained much higher yields [from the KK242 strain], up to 0.82% *mescaline* [d/w], with traces of the *tyramine*-derivatives, as well as *DMPEA* and 3,5-dimethoxy-4-OH-*phenethylamine* (Pardanani et al. 1977). There have been mixed degrees of success, and some failures, with human bioassays of this species, most likely due in part to the unclear taxonomic status of the many varieties which change hands as T. peruvianus (Trout & Friends 1999; pers. comms.). It is important to note that Karel Knize, who made the KK242 collections, recognises "at least 9 different plants he considers to be KK242". Plants obtained directly from Knize, as KK242, differ considerably in comparison to material propagated from KK242 seed in the US, and it is this seed-grown material which is most commonly encountered commercially as KK242 (Trout pers. comm.).

T. poco was found to contain 0.001-0.01% alkaloids, over 50% of which was *hordenine* (Agurell 1969a).

T. puquiensis has a *mescaline*-positive bioassay report, from a c.50cm-long section of a monstrose variety; the diameter of the section was not reported (Trout pers. comm.). Analysis of specimens from 4 locations in Peru found 0.11-0.5% *mescaline* [d/w] (Serrano 2008).

T. purpureopilosus was found to contain 0.01-0.05% alkaloids, consisting of 10-50% each of *tyramine* and N-methyl-*tyramine*.

T. santaensis has been found to have *mescaline*-like activity in human bioassays, with around 455g reported to give perceptible effects (Trout pers. comm.).

T. santiaguensis was found to contain 0.001-0.01% alkaloids, consisting of 10-50% each of *tyramine* and *hordenine* (Agurell et al. 1971).

T. schickendantzii was found to contain 0.001-0.01% alkaloids, over 50% of which was *hordenine*, with traces of N-methyl-*tyramine* (Agurell 1969a).

T. schoenii was found to contain 0.14-0.24% *mescaline* [d/w] (Cjuno et al. 2007; Serrano 2008).

T. scopulicola has not been chemically analysed, yet bioassays indicate it contains similar levels of *mescaline* to T. pachanoi. It appears to be similarly variable in potency. Bioassays of 800-1000g [w/w] have resulted in experiences ranging from mild to intense full-blown psychedelic effects (pers. obs.).

T. skottsbergii has yielded 0.01-0.05% alkaloids, consisting of over 50% *hordenine* and 1-10% *tyramine* (Agurell et al. 1971).

T. smrzianus was psychoactive in a human bioassay, but may contain active compounds other than *mescaline*, as it was said to be "different than San Pedro [T. pachanoi]" (Trout ed. 1999).

T. spachianus has yielded 0.01% candicine, *hordenine* [major alkaloid], 0.004% *tyramine*, and 0.007% N-methyl-*tyramine* (Agurell 1969a; Mata et al. 1976); a specimen cultivated in Indiana apparently yielded *mescaline* (Rätsch 1998), though this requires verification and is likely to be an error. There is one report of a human bioassay claiming it was psychoactive but "different than San Pedro [T. pachanoi]"; other bioassays have been unanimously negative (Trout ed. 1999).

T. strigosus has yielded [d/w] 0.14% *hordenine*, 0.11% candicine, and traces of *mescaline* and *tyramine* (Nieto et al. 1982). Agurell et al. (1971) found 0.01-0.05% alkaloids, which was entirely *hordenine*.

T. taquimbalensis was found to contain 0.01-0.05% alkaloids, mostly *mescaline*, 1-10% *hordenine*, and traces of 3-MeO-*tyramine* and *DMPEA* (Agurell et al. 1971).

T. terscheckii dried branches yielded 0.25-1.2% alkaloids; epidermis yielded 29% of the total alkaloids; central parts yielded 45% of the total alkaloids. They consisted of trichocereine [N,N-dimethyl-*mescaline*] and *mescaline*, in a 5:1 ratio. Some samples contained no *mescaline* in the alkaloidal constituents (Reti & Castrillon 1951). Fresh samples in other tests yielded 0.01-0.05% alkaloids, over 50% of which was *mescaline*, with lesser amounts of trichocereine (Agurell 1969a). It has proven active in human bioassays, some specimens strongly so. Trichocereine was inactive at up to 550mg orally in human experiments (Trout & Friends 1999). However, compared with *mescaline*-dominant species such as T. pachanoi the psychedelic experience obtained from T. terscheckii was described as qualitatively "messier" (R.S. pers. comm. 2002). This species was once thought to contain *DMT* [N,N-dimethyltryptamine] (Schultes & Hofmann 1992), but this was probably a confusion derived from the reported presence of N,N-dimethyl-*mescaline*.

T. thelegonoides yielded 0.01-0.05% alkaloids in fresh material, which was entirely *hordenine* (Agurell et al. 1971); other tests revealed traces of *mescaline* (Siniscalco 1983).

T. thelegonus has yielded 0.01-0.05% alkaloids, consisting of over 50% *hordenine*, and traces of N-methyl-*tyramine* (Agurell et al. 1971).

T. sp. 'Tom Juul's Giant' has proven to be highly variable in potency, from human bioassays, ranging from inactive to "twice as potent as San Pedro". Reports indicate that active compounds besides *mescaline* may be present, though *mescaline* does occur. However, there appear to be at least two varieties of this unclassified species in circulation. The active variety, which has a slight yellowish mottling of the skin, was shown in preliminary analysis to contain *mescaline*, comprising less than 10% of the total [unidentified] alkaloids. The other variety, which lacks mottling, did not contain any *mescaline*, but did contain unidentified tetrahydroisoquinoline alkaloids (Trout & Friends 1999; Trout pers. comm.).

T. uyupampensis has been found to have *mescaline*-like activity in human bioassays (Trout pers. comm.).

T. validus has yielded over 0.05% alkaloids, mostly *mescaline* (Agurell et al. 1971). Apparently a different plant is available horticulturally under this same name; it is a clumping plant with red flowers (Smith 2000), as opposed to the large columnar plant with white flowers described by Curt Backeberg (Backeberg 1959). It is most likely Backeberg's species that was used in Agurell et al's analysis (Smith 2000).

T. vollianus has yielded traces of *mescaline* (Siniscalco 1983).

T. werdermannianus has yielded 0.01-0.05% alkaloids, mostly *mescaline*, with lesser amounts of 3-MeO-*tyramine* and *DMPEA*, and traces of *tyramine* and 3,5-dimethoxy-4-OH-*phenethylamine* [0.1% of total alkaloids] (Agurell 1969a, 1969b). It has ranged from weakly active to highly potent [2-3 times as potent as 'average' T. pachanoi] in human bioassays (Trout & Friends 1999).

An unidentified Trichocereus sp. has been claimed to contain *caffeine* in the seeds, a report which needs verification (Trout ed. 1999).

Trichocereus pachanoi is a cactus to 6m tall, with numerous strict branches, bluish-green, slightly glaucous when young and on new growth (sometimes glabrous), dark green in age, branches up to c.10cm thick, some starting from the base; ribs 4-7(-14), broad at base, obtuse, with slight horizontal or V-shaped depression above areole; areoles small, c.2cm apart; spines 1-4(-7), unequal, very small or completely absent, the longest 1-2cm long (usually much less), dark yellow to brown. Flower buds pointed; flowers very large, funnel-shaped, 19-25cm long, to 20cm diam., white, borne near top of branches, night-blooming, very fragrant; outer perianth segments brownish-red; inner perianth segments oblong, white; flower tube bearing numerous scales, their axils bearing long hairs; filaments long, weak, greenish; style greenish below, white above; throat stamens clearly separate, numerous, filiform, arranged in 2 groups; stigma lobes numerous, linear, yellowish; ovary covered with black curled hairs; axils of scales on flower tube and fruit bearing long black hairs. Fruit without bristles or spines, dull coloured.

Andean Ecuador & Peru (Britton & Rose 1963; Cullman et al. 1986; Ostolaza 1984; Trout & Friends 1999; pers. obs.).

There is a great deal of confusion over the taxonomy of the genus Trichocereus. Many of the original descriptions have proven insufficient in reliably separating species. This is largely due to botanists not examining a wide variety of material from different locations, and growing under different conditions. Even within one batch of seed for a given species, much variation will be noted in the resulting plants; large variations in morphology can also occur through different stages in the life of a plant. T. bridgesii, T. macrogonus, T. pachanoi and T. peruvianus all have inadequate descriptions which do not firmly distinguish these species from one another, as a group, or from other lesser-known species of similar appearance. All of them have been observed to intergrade to varying degrees, and hybrids are known, as they are also with T. scopulicola and T. sp. 'Tom Juul's Giant', two more similar species. T. pachanoi, and some of the variable forms of T. bridgesii, are usually easy to distinguish at species level from the others. However, long-spined forms of T. pachanoi and short-spined forms of T. peruvianus are also known, which further confuses matters (pers. obs.; Trout pers. comms.). Interestingly, in n.e. Peru the 'wild' San Pedro ['San Pedro cimarrón'] said to be more potent than 'true' or cultivated San Pedro ['San Pedro legitimo'] has long spines and may in fact be T. peruvianus (De Feo 2003). T. macrogonus and T. peruvianus are also difficult to separate in practice, due to the insufficient description of the former. There are also problems with both botanists and horticulturalists lumping many different, but similar species, into one designation, particularly with T. peruvianus, which was described by Ritter as a form of T. pachanoi. It seems very likely that there are as-yet undescribed species, which are morphologically similar to other known Trichocereus spp. It is also a strong likelihood that many of the intergrading plants found in this genus are natural hybrids that have become firmly established over hundreds or thousands of years. Many species are showing up in cultivation which have not been neatly fitted to any known and described species. This is a vague and highly confusing area even for the 'experts'. Clearly much work needs to be done to revise the classification of this genus (pers. obs.; Trout pers. comms).

Many cultivators of plants from this genus feel that the currently accepted reclassification of all species into Echinopsis (see Rowley 1974; and the highly confusing and seemingly irrational reclassifications listed in Hunt 1999) is too broad a generalisation, although the dividing lines between these genera are not firm. The best compromise may be to classify Trichocereus as a subgenus of Echinopsis. Coordinated work is needed between cultivators, collectors and botanists worldwide to clarify this taxonomic mess, as well as to classify the unidentified species or strains, and determine the extent of their relationships in the wild. The main problem with the classifications and synonyms given by Hunt (1999) and Rowley (1974) is that no new descriptions were written to clarify and justify the revisions, and it is even doubtful that any taxonomic study of living specimens was undertaken, with much relying solely on seed morphology analysis. Comparison of horticultural material with that from the wild, at all stages of growth and from many locations, as well as genetic and chemotaxonomic study, is well overdue. It would be a shame if the chemical content of some of these species were a factor in preventing such scientific work. See Trout & Friends (1999) for a more in-depth discussion of this grey area.

Cereus peruvianus is sometimes misrepresented as being T. peruvianus by unscrupulous cactus-dealers, due to the reputation of the latter as having a high alkaloid content. T. peruvianus [a very poorly defined species] appears broadly similar to T. pachanoi, but has larger spines and areoles, as well as sometimes having a partially prostrate habit with age. It is now sometimes considered a variety of T. pachanoi.

As mentioned earlier, the distinctions between T. macrogonus and T. peruvianus are unclear, and T. cuzcoensis is easily confused with much of what is circulated commercially as T. peruvianus (pers. obs.). T. cuzcoensis is usually distinguished by the yellowish spines [later darkening and turning amber] (Ressler 2000) with swelling at the base, and young growth that is green and not glaucous (Britton & Rose 1963). At least one person believes that active species can be distinguished from inactive species of similar appearance by the presence of glaucous new growth, and a pronounced bluish tinge to the skin. He believes such specimens to be T. macrogonus rather than T. peruvianus (pers. comm.). T. santaensis also lacks a really good description and may be confused with T. cuzcoensis and T. peruvianus.

T. scopulicola is similar in appearance to T. pachanoi, and in Australia, it is much more commonly available from nurseries. Mature plants differ from T. pachanoi in having a more club-shaped branch apex, usually thicker branches, usually only [4-]5[-6] ribs, frequently more depressed and smaller areoles, less prominent spines, and duller skin [not glaucous] with a slightly roughish texture. The quickest way to differentiate between these two species seems to be comparison of the rib profile, between areoles. T. pachanoi generally curves upwards, as though supporting the areole at the top of its curvature; T. scopulicola generally curves downwards, as though slightly over-hanging the areole at the bottom of its curvature, or simply indenting. When closely inspected, the areoles and spination of these two species are also markedly different (pers. obs.). To add to the confusion, the mysterious 'T. cordobensis' has also been confused with T. pachanoi and T. scopulicola, sharing similarities with both. It appears to have a skin texture more similar to T. scopulicola, but new growth appears more like that of T. pachanoi [though larger and more robust]. Spines become stout [though short] and angled, in large areoles [much smaller on some, but not all young growth]. Branches are typically stout. I suspect it might perhaps be a hybrid between T. pachanoi and T. scopulicola (M.S. Smith pers. comm.; pers. obs.).

Cereus colossus [Trout suggests it should be re-named Trichocereus colossus, due to its hairy flower buds] is a poorly defined species. A plant bearing this label at a Botanical Garden in California is superficially similar in appearance to T. scopulicola and T. sp. 'Tom Juul's Giant' [from a distance], and is clearly a Trichocereus sp. rather than a Cereus sp. This plant, whatever it its identity, is suspected of being active. However, the Cereus colossus sign in front of this specimen may represent a deceased plant, according to collection records, leaving the identity of the remaining plant even more unknown [if that is possible!]. The equally poorly-defined T. argentinensis is also suspected of being active (Trout & Friends 1999; Trout pers. comm.).

T. bridgesii is recognised by some taxonomists as three forms [not including monstrose varieties]. T. bridgesii var. brevispinus has 7-8 ribs, and very short spines. T. bridgesii var. lageniformis has clavate stems, 6-7 ribs, and numerous short spines. T. bridgesii var. longispinus has 4-5 ribs, with very long central spines (Marshall & Bock 1941). The monstrose varieties, all falling under the name T. bridgesii f. monstrosa, are very easy to recognise, though they can still be variable in form. The most commonly encountered form is a low, clumping plant, completely or mostly spineless and cylindrical, with a linear indentation at the apex. It vigorously produces offsets all over the plant, with branches remaining short. In later growth, irregular monstrose and spined portions occur, with usually longer and stronger spines than 'normal' T. bridgesii varieties. Often these plants form a mass of short branches or joints, with new shoots emerging from older branches [which still may be only 6cm long or less at the time], and sometimes from relatively young shoots. The other main variety produces mostly only longer branches, exceeding 30cm in length and mostly spineless. All such monstrose varieties share the fact that their ribs are absent, or indistinct at best. T. bridgesii f. monstrosa is often quite slow-growing, though I have seen it put out bursts of rapid growth that were surprising in their vigour (Backeberg 1959; pers. obs.)! T. bridgesii is highly variable in spination, even on the same plant over time, and firm distinctions between the proposed varieties can sometimes be difficult or impossible to make, as Backeberg (1959) noted.

Trichocereus spp. are easy to grow from seed [treat like other cacti seed, though artificial heat is often not needed], and very easy to grow from cuttings [for most species]. These plants constantly amaze me with their vitality and persistence! I have seen new growth emerge from a small piece of branch-cutting which had been left inside sitting on a piece of glass for months, and had been assumed to be dead. It had only been kept to that point because I couldn't bring myself to dispose of it. They like to be planted in well-drained ground when older, and once established will show much more growth than if kept potted. Regular feeding with dilute [1/5-1/10 of recommended concentration] organic fertiliser will improve growth and [reputedly] alkaloid content – the latter especially if using fertiliser high in ammoniacal nitrogen. Many species can handle daily watering when hot and sunny, though water should not splash on the plant itself. This may cause sunburning. Full sun is appreciated for some of the day, but young plants and those bought from indoor nurseries need to be adjusted to it gradually. Most species prefer strong light, but not full sun. T. bridgesii should be watered less than many other Trichocereus spp. – the monstrose form needs even less water. Avoid calcareous soils for this species. Patience will be required for many of the larger species, which can be very slow-growing. Most of the 'pachanoid' or 'peruvianoid' species are fast-growing when happy and healthy (Trout & Friends 1999; pers. obs.).

TRICHOCLINE

(Compositae/Asteraceae)

Trichocline dealbata *(Hook. et Arnot) Benth. et Hook. f. ex Griseb.* **(Chaetanthera dealbata** *Hook. et Arn.***; C. parviflora** *Phil.***)** – coro, contrayerba

Trichocline exscapa *Grisebach* – coro, contrayerba

Trichocline reptans *(Wedd.) Rob.* **(Bichenia reptans** *Wedd.***; Gerbera incana ssp. reptans** *(Wedd.) Kuntze***)** – coro, contrayerba

The roots of these Argentinian herbs were once added to the alcoholic 'chicha' brew [see *Methods of Ingestion*] of the Calchaqui. More recently, they have been reported to be powdered and smoked, alone or with tobacco [see **Nicotiana**], as a narcotic by the Mocovie, Toba and Mataco. T. reptans is the species most often used, as it is most common. The roots are also used as a fumitory and stomach-ache treatment (Zardini 1977).

Chemical studies are lacking for the above species (Zardini 1977).

T. incana leaf and stem [harv. Jan., Salta Prov., Argentina] yielded

furocoumarins, including 0.88% trichoclin, 0.23% phellopterin and 0.1% isopimpinellin (Miyakado et al. 1978).

Trichocline dealbata is a rhizomatous perennial herb, rhizomes dense, vertical or oblique, much-branched. Leaves in basal rosettes, leaves obovate or spatulate, obtuse, attenuate at base to a large petiole, margin irregularly crenate, wooly or glabrescent on upper side, densely tomentose on underside, 5-12 x 3-6mm; petiole 6-20mm long. Inflorescence a scape, 15-50mm long, arising from base, wooly or downy; flowers yellow or orange, capitula solitary, involucre hemispherical, 10mm high x 10-15mm diam., receptacle flat; involucral bracts overlapping, in 4-5 series, lanceolate, acute, tomentulose on dorsal side, herbaceous or membranaceous; marginal flowers female, c.20, corolla long and bilabiate, outer lip liguliform and tridentate at apex, inner lip bifid, tomentose within, 8-9mm; disc flowers hermaphrodite, corolla bilabiate with lips +- the same length, outer lip tridentate and inner lip bifid; anthers sagittate, connective lanceolate, acute, lateral half ending below in long, linear tails; style short, bilobed, lobulate, redundant in apex. Achenes short, turbinate, densely papillose; pappus white, formed by numerous simple hairs, denticulate.

Endemic to the mountain range of Mendoza, and north of Neuquen, to 2000m; Argentina (Correa 1971).

TURBINA

(Convolvulaceae)

Turbina corymbosa *(L.) Rafinesque* **(Convolvulus corymbosus** *L.***; C. multiflorus** *Kunth***; C. sidaefolius** *Kunth***; Ipomoea burmannii** *Choisy***; I. corymbosa** *(L.) Roth ex Roem. et Schult.***; I. sidaefolia** *Choisy***; Legendrea corymbosa** *(L.) Ooststr.***; Rivea corymbosa** *(L.) Hallier f.***)** – ololiuqui, coaxihuitl, coatlxoxouhwui, piule, xtabentum, amukia, nosolena, yucayaha, bado, bado shnaash, quahn shnaash, ma'zhun paHK ['bones of the children'], snake plant, Christmas vine

The seeds ['ololiuqui' – roughly translated as 'round thing'] of this plant ['coaxihuitl' or 'coatlxoxouhwui' – 'snake plant'] were used by the ancient Aztecs and probably the Mayans, primarily as a sacred shamanic plant for divination. The flowers are believed to be depicted on the statue of the Aztec deity Xochipilli, 'Prince of flowers', which shows him permanently enthroned in a state of shamanic voyage. The seeds are still used by the Zapotec, Yucatan Maya, Chinantec, Mazatec and Mixtec in Mexico, consumed at night in dark and silence for divination. The seeds were once ground and drunk with milk and pepper [see **Piper 1**] as a kind of panacaea, specifically treating pain and inflammation. Often, however, the leaves are the part used for medicinal purposes, except for in aiding childbirth, when c.33 seeds may be taken. The Aztecs used it, mixed with peyote [see **Lophophora**], **Psilocybe** mushrooms and **Datura** to treat 'aquatic fever', which was probably malaria. It was also given topically mixed with **Psilocybe** mushrooms and **Datura** to treat gout. The seeds may also have been mixed with tobacco [see **Nicotiana**] and the burnt remains of venomous insects, and rubbed over the body by shamans as a topical inebriant.

Today, the seeds are used by traditional healers in Mexico as an aphrodisiac which treats menstrual disorders, infertility and fever. For divination, Mixe shamans are known to ingest them ['ma'zhun paHK'] in a dosage of 26 seeds, which are ground in a metate by a 10-15 year-old virgin, and infused in cold water before being strained out and the water drunk [see **Ipomoea**]. In San Baltazar Guelavila, the remaining seed paste is also spread over the top of the head and the veins of the arms, for topical absorption. Zapotec shamans end their curing ritual with the seeds by 'sucking' ['se chupa'] parts of the patient's body [often done with mezcal or water in the mouth], to remove the effects of the sacrament. It is said that insanity can result if this final procedure is not carried out. The shaman begins with the tip of one of the little fingers, proceeding to the other fingertips, up one side of an arm to the shoulder, then on the inside arm from wrist to shoulder, with the same on the other arm, then the middle of the forehead, sides of the forehead, and each side of the head from behind the ear to the shoulder; this may need to be repeated several times, at intervals of a few hours (Diaz 1979; Emboden 1979a; Fields 1969; Lipp 1990; Ott 1993; Rätsch 1992; Schultes & Hofmann 1980, 1992; Wasson 1961, 1963, 1973).

The traditional dosage of the seeds is often stated as the amount it takes to fill a bottle cap; this may be up to 100 seeds or more. They are finely ground and infused in cold water for several hours or up to 1 day, before being strained finely and drunk. Effects are sometimes similar to low doses of LSD, yet with more sedation and physical side-effects [abdominal cramps, nausea, vertigo etc.]. See **Ipomoea** for further discussion. The seeds contain ergot-type indole alkaloids [see **Claviceps**] which are uterotonic, and should not be taken by pregnant women (Osmond 1955; Ott 1993; Wasson 1963).

T. corymbosa seed has yielded [w/w] 0.012-0.06% indole alkaloids – of this, 16.2% may be *tryptophan*, 6.9% *chanoclavine*, 33.7% a mixture of *penniclavine* and isoergine [or up to 34.88% isoergine alone], 18.3-47.33% *ergine*, 2.7% *elymoclavine*, 3.7% *ergonovine* and 3.3% ergometrinine, as well as *agroclavine*, *lysergol*, lysergene, molliclavine, isosetoclavine, lysergic acid α-OH-ethylamide and its iso-derivative, and 9 other unidentified indole alkaloids; the levels of total clavine alkaloids may be as low as 16.2% of the total alkaloids. Seeds also contain the diterpene glycosides ent-16-α-17,19-kauranetriol-17-O,19-O-di-O-β-D-glucopyranoside and turbicoryn, as well as purgative resins and galactomannan; lipids may account for up to 8% of the seed, and one new diterpene glycoside was found at 0.2%. Alkaloids appear to be concentrated entirely in the embryo of the seed; none were found in the seed coat (Chao & Der Marderosian 1973a; Der Marderosian & Youngken 1966; Federico et al. 1993; Franco et al. 1990; Genest 1965; Genest & Sahasrabudhe 1966; Hofmann 1961, 1963; Nair et al. 1987; Ott 1993; Taber et al. 1963a). Leaves and stems, but not the roots, also contain indoles. The content increases with age; 9 month old plants yielded 0.027% alkaloids from leaf, and 0.012% from stem. These consisted of *ergine* and isoergine, as well as at least 2 other unidentified ergot-type alkaloids (Taber et al. 1963b). It should also be noted that the samples in this test were not exhaustively extracted, and the true alkaloid levels are probably higher.

The related T. abutiloides contains calystegines [see **Convolvulus**] in its roots (Schimming et al. 1998).

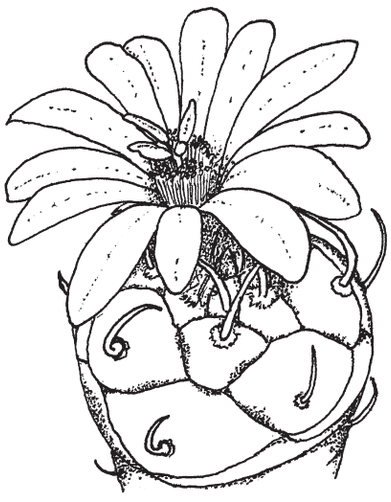
Turbina corymbosa is a large herbaceous or nearly woody climber. Leaves alternate, heart-shaped, ovate, to 10.2cm long, 4.5cm wide, base cordate, margins entire. Inflorescences many-flowered cymes; calyx lobes ovate to oblong, obtuse, enlarging in fruit; corolla white with greenish stripes, campanulate, 2-4cm long, to 3.8cm wide, centre yellowish, glabrous or sparsely hairy outside along stripes. Fruit dry, indehiscent, woody or leathery, enclosed in enlarged calyx, ovoid-oblong to ellipsoidal with persistent enlarged sepals; bears a single seed, hard, roundish, irregularly ovoid, greyish to light brown, 3-5.5mm long, 3-3.5mm wide, ventral surface with a very slight central shallow longitudinal groove near the proximal end of which is a circular hilar depression with numerous trichomes on its periphery.

Native to tropical America; introduced and naturalised in the old world (Bailey & Bailey 1976; Der Marderosian et al. 1964; Schultes & Hofmann 1980).

To cultivate from seed, nick the coat or soak in just-boiled water for several hours before planting; plant 1cm deep, at least 15cm apart, in a strong, well-drained soil with plenty of sun and water. In colder climates they may need to be started indoors in a greenhouse. Frost sensitive (Grubber 1973; pers. obs.).

TURBINICARPUS

(Cactaceae)



TURBINICARPUS SCHMIEDICKIANUS VAR. SCHWARZII

Turbinicarpus alonsoi *Glass et Arias*

Turbinicarpus lophophoroides *(Werd.) Buxb. et Backeberg* **(Strombocactus lophophoroides** *F. Knuth et Backeb.***; Thelocactus lophophoroides** *Werd.***; Toumeya lophophoroides** *Bravo et Marshall***)**

Turbinicarpus pseudomacrochele *(Backeb.) F. Buxb. et Backeb.* **(Strombocactus pseudomacrochele** *Backeb.***; Toumeya pseudomacrochele** *Bravo et Marshall***)**

Turbinicarpus pseudomacrochele var. krainzianus *(Frank) Glass et Foster* **(T. krainzianus** *(Frank) Backeb.***; Toumeya krainziana** *Frank***; To. pseudomacrochele var. krainziana** *Kladiwa***)**

Turbinicarpus pseudopectinatus *(Backeb.) Gl. et F.* **(Pelecyphora pseudopectinata** *Backeb.***)**

Turbinicarpus schmiedickianus *(Bödeker) Buxb. et Backeb.* **(Echinocactus schmiedickianus** *Bödeker***; Strombocactus schmiedickianus** *Berger***; Toumeya schmiedickianus** *Bravo et Marsh.***)**

Turbinicarpus schmiedickianus var. flaviflorus *(Frank et Lau) Gl. et F.*

Turbinicarpus schmiedickianus var. schwarzii *(Shurly) Gl. et F.* **(Strombocactus schwarzii** *Shurly***; T. polaskii** *Backeb*. is apparently a brown-stemmed form**; T. schwarzii** *Backeb.***; Toumeya schwarzii** *Bravo et Marsh.***)**

T. pseudomacrochele first attracted attention as it was believed to possibly be a 'peyotillo', or peyote substitute [see **Lophophora**]. This was due to finding the plant in an area where the researchers were told they could find peyotillos (Bruhn & Bruhn 1973), certainly a dubious basis from which to make such a claim. However, some species have recently been shown to contain low levels of *mescaline* and related alkaloids, warranting a return of interest for the phytochemically-minded.

All yields given below are w/w. Plants analysed by Štarha were cultivated in greenhouses in the Czech Republic.

T. alonsoi yielded 0.0066-0.0084% 6,7-dimethoxy-1,2-dimethyl-1,2,3,4-tetrahydroisoquinoline [6,7-dimethoxy-1,2-dimethyl-THIQ; methyl-*salsolinol*], 0.0044% N-methyl-*tyramine*, 0.004-0.0056% *hordenine* and 0.0015-0.0025% N-methyl-*DMPEA* (Štarha et al. 1999b).

T. lophophoroides yielded more than 0.5% alkaloids, comprising traces of *mescaline*, 0.4-0.62% N-methyl-*mescaline*, traces of N,N-dimethyl-*mescaline* [trichocereine], 0.77-1.31% *phenethylamine*, 1.65-1.99% *tyramine*, 0.02-0.24% N-methyl-*tyramine*, 91.15-92.23% *hordenine*, 0.52-0.57% O-methylanhalidine, 0.07-0.23% anhalinine, 2.25-2.49% *anhalonidine* and 0.38-0.54% *pellotine* (Štarha et al. 1999a).

T. pseudomacrochele has yielded 0.001-0.01% *hordenine* (Bruhn & Bruhn 1973).

T. pseudomacrochele var. krainzianus yielded 0.25-0.5% alkaloids, comprising 2.29-2.67% *mescaline*, 3.18-3.36% N-methyl-*mescaline*, 2.74-3.04% trichocereine, 0.99-1.25% *phenethylamine*, 0.8-1.16% *tyramine*, traces of N-methyl-*tyramine*, 49.05-50.15% *hordenine*, 0.73-0.81% O-methylanhalidine, 29.2-29.28% anhalinine, 2.31-2.57% *anhalonidine* and 0.28-0.44% *pellotine*.

T. pseudopectinata yielded more than 0.5% alkaloids, comprising 0.98-1.24% N-methyl-*mescaline*, traces of trichocereine, 0.86-1.1% *phenethylamine*, 2.99-3.37% *tyramine*, 23.94-26.36% N-methyl-*tyramine*, 59.69-64.53% *hordenine*, 1.77-2.07% O-methylanhalidine and 2.73-3.03% anhalinine (Štarha et al. 1999a); an earlier analysis found more than 0.05% alkaloids, over half of which was *hordenine* (Bruhn & Bruhn 1973).

T. schmiedickianus yielded 0.1-0.25% alkaloids, comprising 0.81-1.23% N-methyl-*mescaline*, traces of trichocereine, 0.89-1.13% *phenethylamine*, 5.32-5.6% *tyramine*, traces of N-methyl-*tyramine*, 41.16-44.88% *hordenine*, 2.34-3.18% O-methylanhalidine, 16.19-18.19% anhalinine, 18.45-21.27% *anhalonidine* and 8.96-9.08% *pellotine*.

T. schmiedickianus var. flaviflorus yielded 0.1-0.25% alkaloids, comprising traces of *mescaline* and N-methyl-*mescaline*, 0.8-1.32% *phenethylamine*, 3.0-3.16% *tyramine*, traces of N-methyl-*tyramine*, 91.34-92.76% *hordenine*, 2.43-3.35% O-methylanhalidine, traces of anhalinine, 0.76-1.0% *anhalonidine* and 0.08-0.22% *pellotine*.

T. schmiedickianus var. schwarzii yielded 0.25-0.5% alkaloids, comprising 2.29-2.67% *mescaline*, 3.18-3.36% N-methyl-*mescaline*, 2.74-3.04% trichocereine, 0.99-1.25% *phenethylamine*, 0.8-1.16% *tyramine*, traces of N-methyl-*tyramine*, 49.05-50.15% *hordenine*, 0.73-0.81% O-methylanhalidine, 29.2-29.28% anhalinine, 2.31-2.57% *anhalonidine* and 0.28-0.44% *pellotine*.

T. schmiedickianus var. dickisoniae was also analysed, but was devoid of *mescaline*, N-methyl-*mescaline*, or trichocereine (Štarha et al. 1999a).

Turbinicarpus schmiedickianus var. schwarzii is a solitary cactus c.4-5cm wide, to 5cm tall, body like **Lophophora** spp., pale green to bluish- or brownish-green; tubercles arranged in 5-8 spirals, 4-angled and completely flat, with fine spots; spines 1-5, usually only 1, to 2cm long, strong, long, curving upward, some projecting above the crown, pale to dark, soon falling off. Flowers white to lavender coloured, 3cm long, 2.5-4cm wide; fruit a laterally bursting berry.

Mexico [San Luis Potosi] (Cullmann et al. 1986; Innes & Glass 1991); usually under shrubs in heavy, black earth.

May be prone to rot, but can withstand low temperatures for brief periods (Trout & Friends 1999).

TURNERA

(Turneraceae)

Turnera diffusa *Willd. ex Schult.* **(T. aphrodisiaca** *Ward***; T. diffusa var. aphrodisiaca** *(Ward) Urb.***; T. humifusa** *Endl.***; T. microphylla** *Desv.***)** – damiana, Mexican damiana, mis kok ['asthma broom'], x misib kok, granizo, hierba de la pastora ['herb of the shepherdess'], hierba del venado ['herb of the deer'], oreganillo, mejorana, cumana, salvia amarilla ['yellow sage']

Turnera opifera *Cambess*

Turnera ulmifolia *L.* **(T. alba** *Liebm.***; T. angustifolia** *Mill.***; T. caerulea** *DC.***; T. mollis** *Kunth***; T. peruviana** *Willd. ex Roem. et Schult.***; T. trioniflora** *Sims***; T. velutina** *C. Presl***)** – la coquette ['the pretty one']

'Damiana' [T. diffusa] is a popular female aphrodisiac herb which has long been used by Mexican women, who may consume a cup of the infused herb several hours before sexual intercourse. It has sometimes been added to 'pulqué', the fermented drink made from Agave spp. [see *Methods of Ingestion*]. The Mayans used it to treat asthma, and as an aphrodisiac. The herb acts as a stimulating nerve tonic, diuretic, mild laxative, and antiperiodic, increases blood flow to the lower abdominal area, and is mildly irritating to the genito-urinary tract when excreted. A usual dose for infusion [or brief light decoction] is 2 tablespoons; the herb may be extracted more efficiently into alcohol. The herb may also be smoked for its mild euphoriant effects; good results may also be obtained by smoking the herb at the same time as drinking the tea, and smoking it mixed with other psychotropic herbs. Some find the smoke quite harsh, and prefer to smoke it through a water-pipe (Heffern 1974; Hutchens 1973, 1992; Jiu 1966; Miller 1985; Rätsch 1990; Siegel 1976). In general, women seem to find the effects of damiana stronger than do men (pers. comms.). Rat experiments have shown that the herb has little aphrodisiac effect in 'sexually potent' rodents, but produced improvements in impotent or sluggish animals (Arletti et al. 1999).

In Australia and other countries, the herb has been a common major ingredient of commercial 'mull-mix' herbal smoking mixtures intended for use with **Cannabis**, as an alternative to tobacco [see **Nicotiana**] (pers. obs.). However, few vendors seem to admit to the identity of any ingredients, and commonly claim the mixtures consist of 'horse chaff' [probably to discourage people from making their own]. Of course, given the number of rip-off merchants lurking around these days, it would not be unlikely that some people are being sold 'horse chaff'.

In Brazil, T. opifera and T. ulmifolia are made into a tea and drunk daily as a tonic. In the Republic of Seychelles, the latter is used to treat eye ailments (Rätsch 1990). In Mexico, Chrysactinia mexicana ['false damiana'] is sometimes used as a substitute for true damiana (Dominguez & Hinojosa 1976).

T. diffusa leaves have yielded 0.2-0.9% essential oil, containing 2% α-*pinene*, β-*pinene*, 11% 1,8-cineol [sometimes not present], p-cymene [sometimes not present], thymol, α-copaene, β-cadinene, calamenene and β-sitosterol; as well as arbutin, triocosanone, triacontane, hexacosanol-1, 14% resin, 3.5% tannin, 6% starch, the flavone gonzalitosin I [5-OH-7,3',4'-trimethoxyflavone], a cyanogenic glycoside and a bitter amorphous substance called damianin. *Caffeine* has also been reported, though this has not been followed up for verification (Dominguez & Hinojosa 1976; Hutchens 1973; Mabey et al. ed. 1990).

T. ulmifolia contains cyanogenic glycosides, including deidaclin; it is sometimes fed on by a **Heliconius** sp. (Spencer 1988).

Turnera diffusa is a shrub 30-200cm tall, with slender brownish branches. Leaves estipulate, alternate, oblong to rhombic-ovate, 1-2cm long, cuneate at base, acute to obtuse at apex, pilose to tomentose beneath, dark green and often glabrous or essentially so above, margin crenate-serrate to dentate, often with 2 glands at base; petioles short. Flowers axillary and usually solitary, perfect; calyx tubular or campanulate, 5-toothed, 4-5mm long, yellowish, the narrowly-lance-triangular teeth nearly as long as the tube; petals 5, bright yellow or orange-yellow, 8-12mm long, inserted on calyx tube, distinct, contorted in bud; stamens 5, inserted at base of corolla tube; anthers 2-celled, splitting lengthwise. Ovary superior, 1-celled, with 3 parietal placentae; style branches 3; stigmas fringed apically. Fruit a capsule 2.5-5mm long, loculicidally 3-valved, valves widely spreading at dehiscence, a placenta in the middle of each valve; seeds pitted, arillate. Fl. Jan.-Jul.

Dry ridges and hillsides; Lower Sonoran Zone to Tropical Zone, s. Baja California, central Sonora and Texas south through Mexico, the West Indies, and C. America to S. America (Shreve & Wiggins 1964).

Propagation from seed is very difficult due to naturally low seed viability. Export of live plants or seeds from Mexico is prohibited (Torsten pers. comm. 2001). Grow in good quality soil with full sun; water freely from spring to autumn, sparingly in winter. Grow outdoors in hot climates, in a greenhouse in colder climates. Harvest leaves when plant is flowering, and dry them in a cool, shady spot (Grubber 1973).

UNCARIA

(Rubiaceae)

Uncaria acida *(Hunt.) Roxb.*

Uncaria attenuata *Korth.*

Uncaria barbata *Merr.*

Uncaria borneensis *Havil.*
Uncaria callophylla *Korth.*
Uncaria canescens *Korth.*
Uncaria elliptica *R. Br. ex D. Don.*
Uncaria gambir *(Hunt.) Roxb.* **(Nauclea gambir** *Hunter***)** – gambir, pale catechu, khadir, katha
Uncaria guianensis *(Aubl.) Gmel.* **(U. aculeata** *Willd.***; U. spinosa** *Räuschel***; Nauclea aculeata** *(Willd.) Willd.***; Ourouparia guianensis** *Aubl.***)** – garabata
Uncaria nervosa *Elmer*
Uncaria orientalis *Guill.* – tevi-cow
Uncaria quadrangularis *Geddes* **(U. homomalla** *Miq.***; Uruparia homomalla** *(Miq.) Kuntze***)**
Uncaria rhynchophylla *(Miq.) Miq. ex Havil.* **(Nauclea rhynchophylla** *Miq.***; Ourouparia rhynchophylla** *(Miq.) Matsum.***)** – pale catechu, cho-to-ko, gou teng
Uncaria sessilifructus *Roxb.* **(U. tonkinensis** *Havil.***; Nauclea sessilifructus** *(Roxb.) D. Dietr.***; Uruparia sessilifructus** *(Roxb.) Kuntze***)** – gou teng, day cau muc
Uncaria sinensis *(Oliv.) Havil.* **(U. membranifolia** *F.C. How***; Nauclea sinensis** *Oliv.***)** – gou teng
Uncaria tomentosa *(Willd. ex Roem. et Schult.) DC.* **(U. surinamensis** *Miq.***; U. tomentosa var. dioica** *Bremek.***; Nauclea aculeata** *Kunth***; N. tomentosa** *Willd. ex Roem. et Schult.***; Ourouparia tomentosa** *(Willd. ex Roem. et Schult.) K. Schum.***)** – una de gato, cat's claw
Uncaria spp.

U. guianensis is used as an ayahuasca additive in Amazonia [see **Banisteriopsis**] (McKenna et al. 1995), though it is unclear whether its presence is for therapeutic or psychotropic reasons. A leaf decoction of the plant is sometimes made to treat dysentery (Usher 1974). U. tomentosa is used traditionally in Peru in the form of a bark infusion, to treat arthritis, gastritis, asthma, weakness, wounds, inflammation, menstrual difficulties, cancer and some skin diseases. It is also used as a disease-preventative tonic (Aquino et al. 1989; Jones 1995; Laus et al. 1997). In animal experiments, a water-extract of the herb has been shown to stimulate immune function and DNA repair, as well as being non-toxic with extended use (Sheng et al. 2000). Anti-tumour activity has also been reported (Mohamed et al. 2000). U. tomentosa has become popular in the west as an all-round tonic medicine, and as a result of its mass-consumption, it is becoming threatened in its natural range (Jones 1995; pers. comms.; pers. obs.).

Several Uncaria spp. are used in TCM [as 'gou teng'] – U. hissata, U. macrophylla, U. rhynchophylla, U. sessilifructus and U. sinensis are all used interchangeably. The dried stem and hooked thorns of the plants are used as an antispasmodic sedative to treat dizziness, hypertension-related headache, cerebral arteriosclerosis, and childhood epilepsy. The herb is also sometimes given in the 8th month of pregnancy, to reduce foetal movement and post-partum spasms (Bremness 1994; Huang 1993; Kanatani et al. 1984; Keys 1976). U. sinensis has been shown to improve "the disruption of spatial cognition in rats" (Mohamed et al. 2000).

U. sessilifructus bark is chewed in Indochina as a betel nut substitute [see **Areca**], and the leaves of U. gambir are sometimes chewed with betel nut. U. acida has been similarly employed (Cooke 1860; Gowda 1951; Phillipson et al. 1978; Usher 1974). Also in this part of the world, leaves of U. quadrangularis are often chewed as a 'kratom' substitute [see **Mitragyna**] (Tantivatana et al. 1979). It is said that elephants will become docile after having Uncaria spp. rubbed on them (Phillipson et al. 1978). A dried water extract of U. gambir young leaves and shoots constitutes the astringent drug 'pale catechu' or 'catechu pallidum' [see also **Acacia**] (Felter & Lloyd 1898).

'Gou teng' antagonises *caffeine*-induced CNS-stimulation and reduces cortical excitation, as well as lowering blood pressure over time. The drug contains indole-type alkaloids including rhynchophylline [stimulates respiration and lowers blood pressure in small doses, paralyses respiration and causes ataxia in high doses; antipyretic, paralyses sympathetic nerve endings], isorhynchophylline [competitive 5-HT2a receptor antagonist], corynoxeine, corynantheine [partial 5-HT receptor agonist, inhibits *serotonin* binding], isocorynoxeine [competitive 5-HT2a receptor antagonist], hirsutine [depresses nerve response] and hirsuteine (Harborne & Baxter ed. 1993; Huang 1993; Kanatani et al. 1984; Kawazoe et al. 1991; Keys 1976; Matsumoto et al. 2005). Indoles found in the genus, consisting mostly of representatives from the oxindole, hetero-*yohimbine*, β-carboline, roxburghine, and pyridinoindoloquinolizidinone groups, have varied physiological activities, and their presence in different species may vary greatly.

U. acida leaf has yielded 0.03-2.03% alkaloids, including *harman*, rhynchophylline and isorhynchophylline (Phillipson et al. 1978); others did not find any alkaloids (Kam et al. 1992).

U. attenuata leaf has yielded 0.03-2.32% alkaloids, including *harman*, corynoxeine, isocorynoxeine, rhynchophylline, isorhynchophylline, hirsuteine, dihydrocorynantheine [same *serotonin* activity as corynantheine – see above], dihydrocorynantheine pseudoindoxyl, epiallocorynantheine, uncarines A & B [isomers of *mitraphylline*], *mitraphylline*, isomitraphylline, akkuamigine, 3-iso-*ajmalicine*, 19-epi-3-isoajmalicine, speciophylline [uncarine D], pseudoyohimbine, rotundifoline, isorotundifoline, 7-OH-3-oxo-3,7-secorhynchophylline, 14-α-OH-rauniticine, rauniticine and salacin (Buckingham et al. ed. 1994; Harborne & Baxter ed. 1993; Phillipson & Hemingway 1975a; Phillipson et al. 1978).

U. barbata leaf has yielded 0.07-0.42% alkaloids, including *harman* (Phillipson et al. 1978).

U. borneensis has yielded *harman*, rhynchophylline, isorhynchophylline, corynoxeine, isocorynoxeine, allo-*yohimbine*, pseudoyohimbine and 3-epi-β-*yohimbine* (Kam et al. 1992; Phillipson et al. 1978).

U. callophylla leaves yielded dihydrocorynantheine, callophylline and gambirine as major alkaloids, as well as *yohimbine*, α-*yohimbine*, β-*yohimbine*, pseudoyohimbine and other alkaloids (Kam et al. 1992).

U. canescens leaf has yielded 0.09-1.79% alkaloids, including *harman* and unidentified oxindole alkaloids; stem yielded 0.53% alkaloids of similar composition (Phillipson & Hemingway 1975a; Phillipson et al. 1978).

U. elliptica leaf has yielded 0.19-1.69% alkaloids, including *harman*, roxburghines, rhynchophylline, *ajmalicine* and other alkaloids; stem has yielded 3.87% alkaloids (Phillipson et al. 1978); no roxburghines were found in another test (Kam et al. 1992).

U. ferrea [from Queensland, Australia] yielded 0.39% alkaloids from leaves and stems, consisting of pteropodine [uncarine C], isopteropodine [uncarine E], speciophylline and uncarine F. In mice, the total alkaloids [oral] had no effect at 100mg/kg; 250-1,000mg/kg resulted in death. In cats, 35mg/kg [i.p.] "led to weak CNS depression, spastic locomotion and crying". Given p.o. [50-100mg/kg], some analgesic and antipyretic effect was observed (CSIRO 1990).

U. gambir leaf has yielded up to 1.1% alkaloids, including tetrahydroalstonine, dihydrocorynantheine, rhynchophylline and other alkaloids; stems also yielded *mitraphylline* (Phillipson et al. 1978); others found no alkaloids (Kam et al. 1992).

U. guianensis has yielded 0.14% alkaloids from leaves [rhynchophylline, isorhynchophylline] and 0.04% from stems [50% speciophylline, 40% pteropodine and 10% *mitraphylline*] (Lavault et al. 1983; Phillipson et al. 1978).

U. longiflora leaves have yielded 1.3% alkaloids, including *mitraphylline*, isomitraphylline, speciophylline, pteropodine, isopteropodine, and their N-oxides, as well as uncarine F (Phillipson & Hemingway 1973a).

U. macrophylla leaves yielded 0.14-0.42% alkaloids, including rhynchophylline, isorhynchophylline, corynoxine [not the same as corynoxeine] and corynoxine B (Phillipson & Hemingway 1973b).

U. nervosa has yielded *harman* and other alkaloids (Phillipson et al. 1978).

U. orientalis leaf has yielded 0.11-1.72% alkaloids, including *harman*, *mitraphylline*, *mitraphylline* N-oxide, isomitraphylline, isomitraphylline N-oxide, pteropodine, pteropodine N-oxide, isopteropodine, isopteropodine N-oxide, *ajmalicine* and speciophylline N-oxide (Phillipson & Hemingway 1975a; Phillipson et al. 1978).

U. quadrangularis leaves have yielded *mitraphylline* and isomitraphylline; bark has yielded pteropodine and isopteropodine (Tantivatana et al. 1979).

U. rhynchophylla – see 'gou teng' above; also, extracts of U. rhynchophylla have shown strong binding to α-2 adrenoreceptors, 5-HT1, 5-HT1A, *dopamine*-1, *GABA*a, *GABA*b and opiate receptors, as well as to the Ca+2 channel (Zhu et al. 1996a).

U. sinensis stems and hooks have been shown to contain rhynchophylline, isorhynchophylline, corynoxeine, isocorynoxeine, hirsutine, hirsuteine, corynantheine, dihydrocorynantheine and geissoschizine methyl ether [inhibits *serotonin* binding, partial 5-HT receptor agonist] (Kanatani et al. 1984).

U. tomentosa root bark has yielded *mitraphylline*, isomitraphylline, speciophylline, uncarine, pteropodine and isopteropodine; the plant has also yielded rhynchophylline, isorhynchophylline, isoajmalicine, akkuamigine, dihydrocorynantheine, corynoxeine, isocorynoxeine, tetrahydroalstonine, speciophylline, hirsutine and hirsuteine (Laus et al. 1997; Sturm & Stuppner 1992). Powdered commercial material [probably stem-bark] yielded 0.35% crude alkaloids, including 0.106% isopteropodine, 0.025% pteropodine, 0.005% *mitraphylline*, 0.027% isorhynchophylline and 0.003% rhynchophylline. An extract of the total alkaloids, as well as the individual constituents rhynchophylline, isorhynchophylline and isopteropodine [as well as pteropodine and *mitraphylline*, which were less potent], antagonised the memory-deficit induced by *hyoscine* (Mohamed et al. 2000).

Harmine and *harmaline* have been said to reside in the genus (Shulgin & Shulgin 1997), though this may be in error, as is the similar generic claim for *mitragynine* (Buckingham et al. ed. 1994), which refers to Phillipson & Hemingway (1975b), who refer to these alkaloids as reference compounds, but do not mention their extraction from, or detection in, any Uncaria spp. Chemical variation within species exists with this genus, and chemotypes probably exist (Laus et al. 1997).

In U. rhynchophylla, and probably other Uncaria spp., oxindole alkaloid content in stem and hooks is highest in the stem parts nearest to the

hooks (Kawazoe et al. 1991).

Uncaria quadrangularis is a climbing shrub, branches 4-angled, hooked, at first pubescent, later glabrous. Leaves ovate-elliptic, apex acuminate, base truncate, 7.5-11.5 x 2.5-4.5cm, upper side reddish-brown, especially near nerves puberulous, under side yellowish-brown, pubescent, lateral nerves on both sides 6, prominent on under side; petiole 6mm long, upper side canaliculate, pubescent, subtended with lanceolate stipules, bifid, 5mm long. Flowers in axillary, solitary heads 2.5cm diam., peduncle 3-4cm long, puberulous, soon subtended with hooks, bracteolate; calyx tube 2mm long, base pilose, bearing long hairs, lobes 5, linear, 1mm long, ciliate; corolla tube 6mm long, externally pubescent, lobes 5, obtuse, 2mm long, upper surface pubescent; stamens 5, filaments very short, attached near base of corolla tube; anthers 1.5mm long, apex obtuse, base sagittate. Ovary 2-loculate; style c.11mm long; stigma fusiform, 2.7mm long.

In scrub, 1300m, Nan, Pu Huat; Siam (Geddes 1928).

UROLOPHUS

(Urolophidae/Dasyatidae)

Urolophus jamaicensis *Cuvier* **(U. torpedinus** *M. et H.***; Urobatis sloani** *Garman***)** – yellow stingray, raya

The pre-Columbian Maya apparently used stingray spines [the stings], often by drawing strings of them through the tongue or other body parts, in the performance of ritual blood-letting. This was a practice of spiritual importance which is thought to have been intended to bring one into contact with the 'vision serpent' as part of the ordeal (Schele & Miller 1986). There is some suggestion that the venom of the species used [thought to have been U. jamaicensis] served as an aphrodisiac and intoxicant at the same time (Rätsch 1992).

Normally, these stingrays sting if stepped on, whipping their tails around from one side to lacerate the flesh with their sting apparatus. The sting possesses a sheath, which is easily damaged and is torn when it enters the skin, exposing the dentate sting itself, and the venom is then released. The main symptom of a sting is pain. Low doses of the venom may cause either peripheral vasodilation or vasoconstriction, while larger doses cause only vasoconstriction. The venom affects the CNS, and other symptoms include irregularities in breathing and heart-rate, vomiting, diarrhoea, sweating and hyperactivity, followed by ataxia and sometimes convulsions.

The venom consists of c.30% protein, 3% nitrogen, 3% carbohydrate, *serotonin*, 5-nucleotidase and phosphodiesterase. It loses its toxicity after 4-18 hours at room temperature, but is more stable at lower temperatures or in 20-40% glycerol (Halstead 1988).

Urolophus jamaicensis is a small stingray to 76cm long; disc (body) smoothly rounded, rhomboid, longer than wide, snout slightly pointed; tail shorter than the disc and with a distinct tail fin at its extremity; tail with a venomous spine near the end, a serrated dagger close to the tail fin. Densely spotted with yellow dots on a variable brownish dark background, with larger pale blotches around disc; ventrally yellowish-white.

Confined to shallow water, usually on sandy or muddy bottoms. It buries itself in the seabed by flapping its pectoral fins, and is said to feed on small fish, shrimps and worms it disturbs. They also raise the front of their disc to form a tunnel to attract prey seeking shelter. Gives birth to live young in litters of 3-4. Easily approached, very common in harbours and bays.

West tropical Atlantic from s. Caribbean to Florida, occasionally to N. Carolina (Halstead 1988; Lieske & Myers 1994).

URTICA

(Urticaceae)

Urtica dioica *L.* **(U. galeopsifolia** *Wierzb. ex Opiz***)** – common nettle, stinging nettle
Urtica parvifolia *Buch.-Ham.* – stinging nettle
Urtica pilulifera *L.* – Roman nettle, stinging nettle

Most people know of nettles only as the small weeds that cause a painful sting when touched [the sting loses its power when the herb is heated or dried], though the juice of the plant can treat the same sting! The cooked young greens make a nutritious vegetable, and the plant is also an excellent fertiliser. The whole plant is used to treat digestive problems, haemorrhoids, skin complaints, arthritis and gout, stimulate circulation, and act as an astringent diuretic. The rhizome may be used as a scalp tonic, and the seeds treat tuberculosis and bronchitis. It also has a reputation as a blood purifier, probably due to its nutritive and diuretic properties (Bremness 1994; Chevallier 1996; Chiej 1984). Magically, nettles have been used to ward off negative influences, or to induce lust (Cunningham 1994). One means of attaining these aphrodisiac effects is to whip your partner's naked genitals with the fresh plants (Rätsch 1990! A friend reported enjoying a satisfying stimulation from smoking commercially obtained dried nettle leaves [possibly U. dioica] (Baill pers. comm.), which might be explained by some of the known chemical constituents of these herbs.

U. dioica contains *serotonin*, *histamine* and *acetylcholine* in the stings, leaves, and stems (Collier & Chesher 1956; Smith 1977b); the herb also has yielded *acetophenone* (Harborne & Baxter ed. 1993) and glucoquinone, and is rich in minerals, such as iron, calcium, potassium and silicic acid (Chevallier 1996). Roots contain *scopoletin*, lignan glucosides, flavonol glycosides and phenylpropanoids (Chaurasia & Wichtl 1987).

U. parvifolia contains *serotonin*, *histamine* and *acetylcholine* in the leaves (Rastogi & Mehrotra ed. 1990-1993).

U. pilulifera leaf and stem contain *serotonin* (Smith 1977b) and *bufotenine* (Regula 1973a).

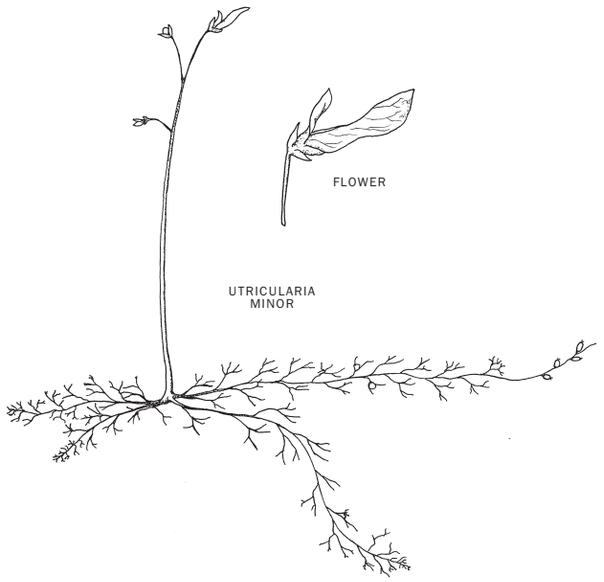
Leaves and stems of U. cubensis, U. ferox, U. membranacea and U. thunbergiana [but not U. urens] contained *serotonin* at levels of 0.000042-0.000126% [w/w]; *serotonin* was also found in the isolated stings of these first 4 species (Regula & Devide 1981).

Urtica pilulifera is an annual, monoecious herb 30-100cm tall, with stinging hairs. Leaves opposite, 2-6cm long, ovate, truncate to subcordate at base, serrate or entire, green below; petiole almost as long as leaf blade; 4 stipules at each node, free. Inflorescence an axillary unisexual raceme, with clustered cymes; females long-pedunculate spikes with flowers in globose heads; males spicate. Female flowers with inflated, deeply-lobed 4-merous perianth, perianth segments +- unequal, the 2 larger enclosing the achene; often with small staminodes; ovary superior, 1-locular, sometimes adnate to perianth; ovule 1, orthotropous; style simple. Male flowers with 4 stamens opposite the perianth segments, inflexed in bud, often with rudimentary ovary. Fruit an achene; seeds usually with endosperm, embryo straight.

S. Europe, often naturalised elsewhere (Tutin et al. ed. 1964-1980).

UTRICULARIA

(Lentibulariaceae)



Utricularia minor *L.* – lingna, bladderwort

In Ladakh, deep in Himalayan India, the dried, powdered leaves of this small aquatic plant are first roasted on a flat stone [which is being heated on a fire], before being mixed with water and kept underground in a tightly sealed bottle for 10-15 days. The resulting drink is usually consumed only in winter, and is highly intoxicating, occasionally causing death (Navchoo & Buth 1990).

The chemistry of this plant is relatively unknown. Perhaps the presence of a toxic and psychoactive mould [eg. see **Aspergillus**] in the preparation explains some of the above effects. Such a mould could feasibly enter the bottle through air or soil exposure prior to sealing, being prepared in [presumably] unsterile conditions. It is also possible that the plant collects its own active chemicals by leaching toxic algal metabolites from the water [see **Acanthurus et al.**]. The carniverous bladder-traps of some Utricularia spp. have been shown to contain thriving algal populations [especially Cyanophyta] (Botta 1976; Mosto 1979). However, some carniverous plants are known to produce their own toxic psychoactive alkaloids, such as *coniine* produced by Sarracenia flava (Mody et al. 1976).

U. minor from Sweden tested positive for the presence of c.0.003% al-

kaloids (Hultin & Torssell 1965).

The related U. australis has yielded iridoid glycosides, including 0.014% aucubin, 0.0003% gardoside, 0.005% mussaenosidic acid and 0.01% 6-deoxycatalpol (Damtoft et al. 1985).

Utricularia minor is an aquatic herb, with stems creeping on the bottom of shallow water; stems often 10-30cm long, leafy. Leaves alternate, once to several times finely to dichotomously branched, rarely up to 8mm long, often bearing 1-2 bladders; width of segments scarcely reduced after each successive dichotomy, the ultimate segments flat, entire, sharply acuminate; leaves at base of scape linear or spatulate, often evanescent before flowering; scales of scape and branches attached by their bases. Peduncles up to 15cm long, 2-8-flowered, usually minutely bracteate, bearing around the middle a cluster of oblong vesicles; pedicels bracteate and often 2-bracteolate, soon becoming curved and the capsules nodding; scapes simple or branched; racemes few- or many-flowered, rising above the surface of the water; flowers yellow; calyx 2-partite, lobes equal and entire or nearly so, often enlarged in fruit; corolla 8-9mm, 2-lipped, spurred, spur reduced to a mere sac, upper lip entire or emarginate, lower lip 3-6-lobed, 4-8mm long, c. twice as long as upper; palate hardly developed; filaments broad; anthers ovate, 2- or sub-1-celled. Style short; stigma unequally 2-lobed. Capsule globose, as long as calyx; seeds smooth, ellipsoid or ovoid, scrobiculate or glochidiate, testa reticulate. Fl. summer.

Sometimes washed ashore and blooming in wet soil – under these circumstances the dissected leaves may be scarcely apparent, and may be mistaken for other species; it is distinguished by its basally attached lateral bracts.

Alpine w. Himalaya, 3350m; Europe, w. & c. Asia, Greenland, Canada, south to Virginia, Indiana, California and S. Carolina (Gleason 1952; Hooker 1875-1897).

Utricularia spp. are interesting carniverous plants, mostly of aquatic habit. They are called 'bladderworts' because of the bladder-shaped traps which grow from the leaves of aquatic species, and from any part of terrestrial and epiphytic species. These traps are 'set' by expelling water from within themselves, producing a low internal pressure and sealing the door of the trap shut. The bladders have 'hairy' protrusions which funnel the prey [small creatures such as insects and baby fish] close to the door of the trap. Brushing past these hairs triggers the door of the trap to open, causing an influx of water, carrying the prey. The door then shuts and the prey is consumed by the activity of enzymes and bacteria living within the bladders, before the trap re-sets itself to await further food (Pietropaolo & Pietropaolo 1986).

VACCINIUM including some Sclerotinia parasites

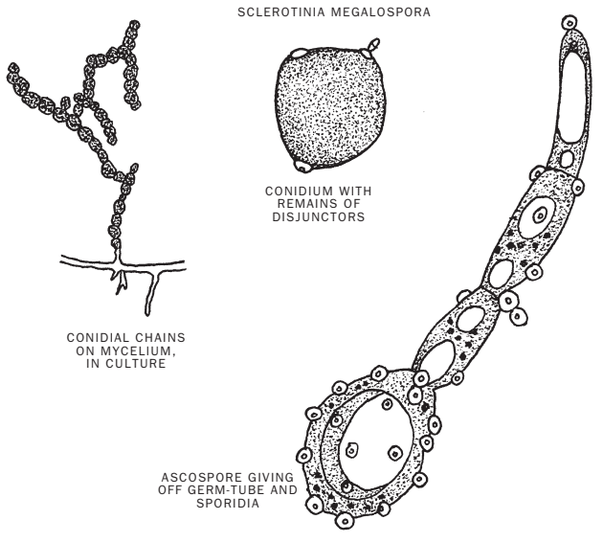
(Ericaceae)

Vaccinium floribundum *Kunth* **(V. crenulatum** *Dunal***; V. dasygynum** *Blake***; V. marginatum** *Dunal***; V. moritzianum var. ovatum** *Klotzsch***; V. mortinia** *Benth.***; V. polystachum** *Benth.***; V. ramosissimum** *Dunal***; V. tatei** *Rusby***; Metagonia marginata** *(Dunal) Nutt.***)** – Andean blueberry, Colombian blueberry, borrachero ['intoxicant'], agraz, chivaco, macha-macha, mortiño

Vaccinium uliginosum *L.* **(V. gaultherioides** *Bigalow***; V. pedris** *(Harshb.) Holub***; V. pubescens** *Wormsk ex Hornem.***; Myrtillus uliginosa** *(L.) Drejer***)** – bog bilberry, bog blueberry, bog whortleberry, northern bilberry, alpine blueberry, trunkelbeere ['drunken berry'], rauschbeere ['inebriating berry'], schwindelbeeren ['dizzy berries'], odon, juolukka

Vaccinium vitis-idaea *L.* **(V. jesoense** *Miq.***; V. vitis-idaea var. genuinum** *Herder***; Rhodococcum vitis-idaea** *(L.) Avror.***)** – cowberry, bog cranberry, rock cranberry, mountain cranberry, foxberry, partridge berry, lingonberry, whortleberry, whimberry, kokemomo

(Helotiae)



Sclerotinia megalospora *Wor.*
Sclerotinia minor *Jagger*

V. uliginosum, a small Eurasian bush, is closely related to the large cranberry [V. macrocarpon], small cranberry [V. oxycoccus], blueberry [or 'bilberry', 'wimberry'; V. myrtillus] and the dingleberry ['mountainberry'; V erythrocarpon]. It was once [and possibly still is] used in Siberia for its berries, which were mixed with **Amanita** muscaria preparations for consumption, and said to have an intoxicating and narcotic effect. Today in Germany and Austria, the berries are reputed to have toxic properties, and children are warned not to eat them lest they "lose their wits". However, despite sometimes causing mild intoxication, the berries are usually considered edible (Rätsch 1992; Von Bibra 1855). Some people have eaten huge quantities with no effect, while one subject reported dizziness, tiredness, visual troubles, bursts of heat and difficulty swallowing after eating 300g of the berries. The typical intoxication also includes psychomotor excitation, mydriasis and vomiting. It has been proposed that the effects may be due to the obscure ascomycete [Sclerotinia megalospora] which often grows parasitically on the leaves and berries, as well as on berries of Empetrum nigrum ['crowberry'] (Festi & Samorini 1996; Von Tubeuf 1897), which has been known as 'rauschbeere' ['inebriating berry'] (Rätsch 1992). Perhaps psychoactive compounds are produced by the plants in response to fungal infection (theobromus pers. comm.). Unfortunately, the chemistry and toxicology of Sclerotinia spp. has been poorly studied, with most research focusing on methods for their eradication from plant crops.

Shakers of N. America smoked V. vitis-idaea as a favoured replacement for **Arctostaphylos**, and it may have inebriating properties (Emboden 1979a). V. reticulatum, a Hawaiian endemic species often growing on new lava flows, is known as ''ôhelo' or ''ôhelo-'ai', and its fruiting branches are thrown into a fiery pit at Kilauea as an offering to Pele, the volcano goddess. The berries are edible, and the dried leaves are sometimes made into a tea (Palmer 2001; Pukui & Elbert 1971). V. floribundum is known as 'borrachero' ['intoxicant'] in Venezuela, and is thus suspected of being psychoactive (Festi & Samorini 1996). Blueberry [V. myrtillus] fruits are used to make a wine in central Europe called 'Heidelbeersejt', or 'Heidelbeerwein', which may be distilled to make a spirit known as 'Heidelbeergeist' (Usher 1974).

V. corymbosum fruits have been shown to contain a large number of compounds, including *eugenol*, iso-*eugenol*, *myristicin* and α-*pinene* (Hirvi & Honkanen 1983).

V. myrtillus leaves, stems, and fruits were shown to contain monotropein [see **Monotropa**] (Swiatek & Komorowski 1973) and arbutin (Trzaski 1954), though another study found no arbutin in the leaves (Walewska 1966); leaves have also yielded hydroquinone [in cats, hydroquinone was toxic orally either in repeated doses of 30-50mg/kg, or single doses of 60-100mg/kg, causing haemolysis and eventual death from respiratory paralysis] (Oettel 1937). The plant has given positive tests for the presence of alkaloids (Zolotnitskaya 1954). Fresh aerial parts yielded traces of the quinolizidine alkaloids myrtine and epimyrtine, via a mild extraction (Slosse & Hootelé 1978, 1981). Berries have been shown to contain a large number of compounds, including methyl-salicylate, *eugenol* and iso-*eugenol* (Hirvi & Honkanen 1983). The leaves of this species are often infected by Sclerotinia baccarum (Von Tubeuf 1897).

V. oxycoccus fruits have yielded β-carboline alkaloids called cannaguinines (Jankowski et al. 1972, 1974).

V. uliginosum leaves have yielded the triterpenes friedelin, ursolic acid and α-amyrin; the sterols β-sitosterol and β-sitosterol-β-D-glucoside;

and condensed tannins. They may also contain oleanolic acid (Nees et al. 1973). Arbutin has been found in the plant (Trzaski 1954). The berries have been found to contain quercetin-3-monogalactoside (Kawaguti et al. 1939), acetic acid, hexanoic acid, hexan-1-ol, cis-3-hexan-1-ol, trans-2-hexen-1-ol, hexanal, trans-2-hexenal, benzyl alcohol, benzaldehyde, α-terpineol, phenol, 4-vinylphenol, 2-MeO-5-vinylphenol, 2-phenylethanol, trans-cinnamylalcohol, and traces of limonene, linalool, myrcenol, nerol, pentan-1-ol, 3-methylbutan-1-ol, octan-1-ol, pentylfuran, vanillin, guaiacol and pyrocatechol (Hirvi & Honkanen 1983).

V. vitis-idaea leaves and stems have yielded monotropein (Swiatek & Komorowski 1973), and up to 10.4% arbutin (Fromard 1985; Trzaski 1954); highest arbutin levels were found in leaves, with highest yields obtained in late summer and autumn (Drathschmidt & Zechner 1939). Pyroside is present in fully-developed leathery leaves, and not in young leaves (Walewska 1966). Leaves have also yielded hydroquinone (Oettel 1937) and quercetin-3-monogalactoside (Kawaguti et al. 1939). V. vitis-idaea leaves and berries are often infected by Sclerotinia vaccinii [S. urnula]; S. oreophila has also been observed on the leaves (Von Tubeuf 1897).

Sclerotinia libertiana [S. sclerotiorum] growing on **Brassica** napus yielded an unidentified alkaloid with uterotonic properties. This species is also found on other vegetable plants, particularly of the Leguminosae (Gradnik 1951).

S. minor mycelium and sclerotia have shown anticholinergic properties, and have been found to contain an alkaloid that was tentatively identified as either *atropine* or *hyoscyamine* (Mutschler & Rochelmeyer 1960).

Vaccinium uliginosum is a deciduous shrub, with stems up to 75(-100)cm, erect, freely branched, arising from a creeping rhizome; twigs terete, usually glabrous, brownish. Leaves alternate, subsessile or very shortly petiolate, 6-25(-35) x 4-12(-20)mm, obovate, entire, obtuse to subacute, glabrous, glaucous, margin slightly revolute. Flowers 4-5-merous, in racemes of 1-3 which terminate short branches bearing only scale-leaves; bracteoles absent; sepals largely, often almost completely connate; calyx lobes rounded, scarious, reddish; corolla rotate to globose, 4-6mm, urceolate, white, usually tinged with pink; lobes short, revolute; stamens 8 or 10; filaments glabrous; anthers with small, subulate appendages, each lobe prolonged apically into a tube with a pore at apex. Ovary included; style inferior. Fruit a berry, 7-10mm, globose to ellipsoid, bluish-black, sweetish.

Widespread in moors, heaths, coniferous woods, subalpine pastures and tundras; n. & c. Europe, extending southwards in mountains to Sierra Nevada, n. Appennini, Albania and Bulgaria (Tutin et al. ed. 1964-1980).

Sclerotinia megalospora is noticeable on the leaf and fruit of the infected plant; observed as a white conidial cushion on midrib of leaf, causing it eventually to wither; sclerotia take over the berry by 'mummification', turning it white and deformed; sclerotia give rise to smooth stalked cup-like ascocarps, their stalks not producing rhizoids; asci containing 8 unicellular hyaline spores, elliptical or spindle-shaped, of varying size; conidia forming chains from mycelium; paraphyses thread-like; rhizoids absent; ascospores large, similar to each other, in a gelatinous envelope, later giving off a germ tube and sporidia; sporocarps consisting of a pseudoprosenchyma (Von Tubeuf 1897).

S. libertiana ['cottony softrot', 'watery softrot', 'white mould'] is a common fungal disease of many plants, particularly **Camellia** spp., Chrysanthemum spp., Dahlia spp., **Narcissus** spp. and **Nicotiana** spp. (Fox 1996).

VALERIANA and some close relatives

(Valerianaceae)

Valeriana adscendens *Trel.* – hornamo morado
Valeriana angustifolia *Turcz.* **(V. officinalis var. latifolia** *Miq.***)**
Valeriana alliariifolia *Vahl*
Valeriana capensis *Thunb.*
Valeriana celtica *L.*
Valeriana dioica *L.*
Valeriana edulis ssp. procera *(Kunth) F.G. Mey.* **(V. 'mexicana'** *DC.***)**
Valeriana excelsa *Poir.*
Valeriana glechomifolia *Meyer*
Valeriana kilimandscharica *Endl.*
Valeriana officinalis *L.* **(V. baltica** *Pleijel***; V. exaltata** *J.C. Mikan***; V. hortensis** *Lam. nom. illeg.***; V. palustris** *Kreyer, non Gars***; V. sylvestris** *S.F. Gray***)** – common valerian, all heal, setwall, garden heliotrope, bloody butcher, vandal root, Capon's trailer, phu, antamilla, tagara, sugandhwala
Valeriana palustris *Gars*
Valeriana phu *L.*
Valeriana sambucifolia *Mik.*
Valeriana simplicifolia *(Rchb.) Kabath*
Valeriana sitchensis ssp. scouleri *(Rydb.) Piper* **(V. scouleri** *Rydb.***)** – Pacific valerian
Valeriana thalictroides *Graebn.*
Valeriana tiliifolia *Troitzky*
Valeriana tripteris *L.*
Valeriana wallichii *DC.* **(V. harmsii** *Graebn.***; V. jatamamsi** *Jones***; V. mairei** *Briq.***; Nardostachys jatamamsi** *(D. Don) DC.***)** – jata mamsi, nakpo, somana, sungandhaval, Indian spikenard
Valerianella olitoria *(L.) Poll.* **(V. locusta** *(L.) Later.***)**
Centranthus angustifolius *(L.) DC.*
Centranthus calcitrapa *(L.) Dufr.*
Centranthus longiflorus *Steven*
Centranthus macrosiphon *Boiss.*
Centranthus ruber *(L.) DC.* – red valerian
Fedia cornucopiae *(L.) Gaertner*
Fedia sulcata *Pomel*
Patrinia scabiosifolia *Fisch. ex Trevir.*
Plectritis spp.

The generic name Valeriana derives from the Latin valere, 'to be in health'. Cats and rats are attracted by the smell of valerian, and it has even been said that the Pied Piper of Hamelyn carried valerian root to lure the rats away from the town, his music being a decoy. The powdered root is sometimes used as 'graveyard dust' in magical practices. The Greeks hung a sprig of it under windows to dispel evil; it was also said to attract lightning and bring a lover. The root used to enjoy huge popularity as a nervine sedative [since the late 16th century in Europe], particularly for symptoms of the so-called 'women's hysteria' or 'vapours'. It returned to popularity during the first two World Wars, for treatment of shell-shock and nervous stress. Valerian root has been used historically by Persian, Nordic, Indian and Chinese herbalists. In Ayurveda and TCM, V. wallichii is used as well as V. officinalis. V. wallichii is said to have similar properties to V. officinalis, yet is more desirable for 'strengthening the mind and promoting awareness'. Excessive use of V. officinalis, however, is said to dull the mind. The most notable property of valerian is its strong nervine action, excellent for promoting sleep. Some studies, and practical experience, have found it to act as a sedative for agitated people, and as a stimulant in the fatigued; old roots are more likely to produce stimulation. It may also be less effective for younger, more energetic people. It has been used to treat anxiety, nervous tension, depression, insomnia, headache, stomach cramps, irritable bowel, diarrhoea, bloating, muscle pain, bronchial spasms, cough, nervous heart conditions, bedwetting, Parkinson's disease and PMS (Bremness 1988; Cunningham 1994; Emboden 1979a; Hobbs 1993; Frawley & Lad 1986; Lawless 1995; Leathwood et al. 1982; Nadkarni 1976; Tucker & Tucker 1988).

The root of the related V. capensis from S. Africa is used for epilepsy and hysteria, and has antispasmodic actions (Watt 1967). In Peru, V. adscendens aerial parts are sometimes added to brews prepared from **Trichocereus** pachanoi to increase the effects; the whole plant has strong purgative properties (Davis 1983; De Feo 2003). In Nepal, V. wallichii rhizome is used in ritual incense (Müller-Ebeling et al. 2002).

Centranthus spp. are also well known sedatives, with chemistry similar to that of Valeriana spp., and C. longiflorus is used as such in Turkey (Demirezer et al. 1999). Though Fedia spp., Patrinia spp. and Plectritis spp. do not have any notable use to date, they also bear similar chemistry or effects to Centranthus spp. and Valeriana spp., and might potentially be used in the same way (Foerster et al. 1984; Funke & Friedrich 1975).

The active compounds in Valeriana and Centranthus are monoterpenoid iridoid esters called valepotriates [sedative, spasmolytic, anticonvulsant, increase *GABA* levels, reduce alcohol-induced concentration deficits; cytotoxic and mutagenic in large amounts], the most important being the valtrates [*valtrate*, isovaltrate, *dihydrovaltrate*, acevaltrate, homovaltrate and IVHD-*valtrate*]; essential oil components [sesquiterpenes]; and small amounts of alkaloids. The valepotriates are unstable, and decompose rapidly to baldrianal and homobaldrianal with the influence of heat, water or stomach acids. These latter two compounds are better absorbed than the valepotriates, and have stronger sedative qualities. Drying the root causes enzymatic formation of isovaleric acid, which creates the characteristic odour of dried valerian root [described by some as 'mousy', or like old socks]. Essential oil makeup is very variable. Excessive use can cause excitability, headaches, uneasiness, insomnia and cardiac irregularities; very high doses can cause CNS paralysis, and should be treated with gastric lavage, charcoal and sodium sulfate.

Fresh or freshly dried roots are more desirable than old roots; most potency may be lost after 1 year. A dose of 1 tsp ground root may be sufficient. The herb may be extracted into alcohol and water as a tincture, or may be steeped as a tea; although the valepotriates and essential oil are not water-soluble, water extracts still have activity (Foerster et al. 1984; Fugh-Berman 2000; Hendricks et al. 1981; Hobbs 1993; Wagner et al. 1980). The official drug consists of the rhizome, roots and stolons, dried below 40°C (Bruneton 1995).

Valeriana adscendens aqueous extract has CNS-depressant effects, and inhibits *GABA* uptake (De Feo 2003).

Valeriana angustifolia has yielded 0.5-6% essential oil [51% acetate, 16% camphene, 7% α-*pinene*, 6.5% β-*pinene*, 5.5% carveyl acetate, 2% limonene, 2% dihydrocarveyl acetate], valepotriates, kanokosides A, B, C

& D, and kessane derivatives. The essential oil is protective against pulmonary oedema in rats, contracts coronary vessels, and is antiarrhythmic (Hobbs 1993).

V. celtica essential oil contains 1.3% *nepetalactone* [see **Nepeta**] (Tucker & Tucker 1988), and mostly isovaleric acid, seychellene and patchouli alcohol [53.4% combined] (Hobbs 1993).

V. edulis ssp. procera root has yielded 7-8% valepotriates (Bruneton 1995; Dossaji & Becker 1981), including *valtrate*, isovaltrate and *dihydrovaltrate* (Hobbs 1993).

V. glechomifolia [harv. Apr., s. Brazil] yielded *valtrate*, acevaltrate, diavaltrate, *dihydrovaltrate*, AHD-*valtrate*, 1-β-aceacevaltrate and dihydrocornin; aerial parts and roots had similar chemical composition (Salles et al. 2000).

V. kilimandscharica has yielded valepotriates including isovaltrate and *valtrate* [major constituents], and traces of *dihydrovaltrate*, acevaltrate and IVHD-*valtrate*; leaves yielded up to 5.89% valepotriates, 5.15% in rhizomes, 3.84% in flowers and 3.17% in stems (Dossaji & Becker 1981).

V. officinalis root has yielded up to 1% essential oil, including valerenic acid, 3-16% valerenal, 0-18% valeranone, valerenol, OH-valerenic acid, acetoxyvalerenic acid, valerenyl esters, valerenone, valene, 0.7-8.6% pacifigorgiol, 2-12% elemol, 9-10% α-kessyl alcohol, maali alcohol, patchouli alcohol, 31% bornyl acetate, 8.2% carvone, 4.3% thymol, isovalerate, caryophyllene, camphene, *pinene*, *borneol*, myrtenol, myrcene, limonene, phellandrene, carvacrol, terpinene, terpinolene, p-cymene, α-fenchene, guaidol, eudesmol, bisabolol, cadinene, curcumene, ergonophylene, kessane, azulene, β-ionone, faurinone, bornyl formate, 1-myrtenyl acetate, 1-myrtenyl-isovalerianate, valenol, kanokonole, *valtrate* and valeridin. Root has also yielded 0.2-2% valepotriates, including *dihydrovaltrate* [breaks down to valtroxal, which is a more effective sedative], isovaltrate [0.25-0.75% of whole root], acevaltrate, isovaleroxy-OH-*dihydrovaltrate*, *dihydrovaltrate*-hydrin [valechlorine], *valtrate*-hydrine B1, *valtrate*-hydrine B2, acetoxyvaltrate-hydrine, and valepotriate glycosides valerisodatum, patrinoside, kanokosides A & B; carboxylic acids, including isovaleric, malic, stearic, palmitic and acetic acids; alkaloids *actinidine* [see **Actinidia**], 8-MeO-*actinidine*, isovaleramide, 0.01% chatinine, 0.01% valerianine, Δ-methylpyrrylketone and dipyridylmethylketone; as well as isoeugenyl-isovalerate, behenic acid [see **Calonyction**], hesperitinic acid, *chlorogenic acid*, caffeic acid, luteolin, diosmetin, kaempferol [MAOI (Sloley et al. 2000); in aerial parts], arachidonic acid, *choline*, *GABA*, *glutamine*, *tyramine* and tannins. Valepotriate content decreases in autumn (Bruneton 1995; Hobbs 1993; Johnson & Waller 1971; Nadkarni 1976; Pethes & Verzár-Petri 1977; Tucker & Tucker 1988).

V. sitchensis ssp. scouleri has yielded 1.12% valepotriates from roots, and 0.033% from leaves, as well as a large quantity of essential oil (Hobbs 1993).

V. thalictroides roots have yielded 14.5% valepotriates, consisting mainly of isovaltrate, as well as *valtrate*, IVHD-*valtrate*, *dihydrovaltrate*, homovaltrate and acevaltrate, in decreasing order of magnitude (Becker et al. 1983).

V. wallichii root has yielded 2.8-3.5% valepotriates, and the flavonoid linarin-isovalerianate, as well as alkaloids; leaf has yielded 1% valepotriates (Bruneton 1995; Dossaji & Becker 1981; Funke & Friedrich 1975; Hobbs 1993). The defatted extract has good sedative properties (Chatterjee et al. 1965).

V. alliariifolia, V. dioica, V. excelsa, V. palustris, V. phu, V. sambucifolia, V. simplicifolia, V. tiliifolia, V. tripteris, Valerianella olitoria, Centranthus angustifolius, C. calcitrapa and C. macrosiphon also contain valepotriates (Funke & Friedrich 1975).

C. longiflorus ssp. longiflorus aerial parts yielded the iridoid glycosides patrinoside and kanokoside A, the valepotriate *valtrate*-hydrine B8, the iridoid lactone longiflorone, quercetin 3-O-rutinoside, oleanolic acid and sitosterol (Demirezer et al. 1999).

C. ruber has yielded 5-7% valepotriates from roots, and up to 1% from leaves, including *valtrate*, acevaltrate, *dihydrovaltrate*, homoacevaltrate, acetoxy-OH-*dihydrovaltrate* [AHD-*valtrate*] and deiso-valeroxy-acetoxyvaltrate; as well as gentioside, gentioflavoside, gentioflavine, gentiopicroside, gentianine, gentianidine and swertiamarin; as well as a small quantity of essential oil (Funke & Friedrich 1975; Handjieva et al. 1978; Hobbs 1993; Marekov 1977).

Fedia cornucopiae and F. sulcata contain valepotriates (Funke & Friedrich 1975).

Patrinia scabiosifolia has yielded 0.1% essential oil [containing patrinine and isopatrinine], as well as isopentanoic acid and saponins [patrinosides]. The essential oil and saponins have sedative and hypnotic actions in humans (Hobbs 1993).

Plectritis brachystemon, P. ciliosa, P. congesta and P. macrocera all contain low levels of *valtrate*s [below 0.1%] in all parts (Foerster et al. 1984).

Valeriana officinalis is a perennial herb, bearing a short rhizome with many hollow rootlets, sometimes stoloniferous; stems (15-)30-150(-240)cm, usually solitary, simple, grooved, hollow, robust, sulcate, pubescent or glabrous. Leaves opposite, pinnate or pinnatisect with 3-25 leaflets, mostly sessile; basal leaves petiolate, in a rosette before stem forms; leaflets linear, lanceolate, elliptical or oblong, with entire or dentate margin. Flowers in compound umbellate cymose clusters, hermaphrodite; calyx teeth 5-15, linear, inrolled in flower, accrescent and plumose in fruit; corolla pink or white, tube 2.5-5mm long, infundibuliform, slightly gibbous near base, 5-lobed, lobes unequal; bracteoles +- equalling fruit; stamens 3. Ovary inferior, 3-locular, 1 loculus with 1 pendent ovule, other 2 sterile, sometimes very small; stigma 5-fid. Fruit 2-5mm, hairy or glabrous, indehiscent, 1-seeded, with feathery persistent calyx and very small sterile loculi; seed endospermic, with straight embryo.

In damp, fertile soil, especially by ditches and stream banks, as well as moist woodland; common wild in Europe [rare in deep south], Britain and n. Asia, frequently cultivated (Bremness 1994; Chiej 1984; Tutin et al. ed. 1964-1980).

Cultivate from seed or root cuttings; sow seed in mid-summer, spaced 40cm apart, keeping constantly moist. Slightly acid, sandy soil increases yields of active compounds. Likes lots of nitrogen. Gather roots and rhizomes in autumn or early spring, on a cool morning. Best dried at 40°C, with airflow; large roots should be cut to shorten drying time (Hobbs 1993). May require protection from cats, as they are so drawn to the smell of the roots [perhaps because of the 'mousy' odour?] that they have been known to dig them out of the ground (theobromus pers. comm.).

VANDA

(Orchidaceae)

Vanda roxburghii *R. Br.* **(V. tesselata** *(Roxb.) Hook.***; Cymbidium tesselloides** *Roxb.***)** – rasna, vandaka, rasna nai, darebanki, tesselated vanda

The flowers of this orchid are decocted and drunk, or tubers ingested, by Ayurvedic shamans and tantric magicians in India to aid entrance into a trance state for divination. This practice may stem from observing the stupefying effect the nectar has on bees (Emboden 1979a; Rätsch 1992). Medicinally, the fragrant, bitter roots are used in oils to be applied externally for nervous system disorders and rheumatism; medicinally, the roots are used interchangeably with those of Acampe papillosa, A. praemorsum or A. wrightiana, or leaves and flowers of V. spathulata. The leaf juice may be dropped into the ear for ear inflammations (Chopra et al. 1958; Dutt 1989; Lawler 1984; Nadkarni 1976). The orchid was also taken in an ancient Sanskrit preparation to "avert calamities"; in another preparation it was "eaten with food by women who wanted sons". It is also contained in some ayurvedic aphrodisiac preparations. Ghee containing V. roxburghii and Eria muscicola [another orchid] reputedly "powerfully excited the venereal appetite". V. spathulata [flowers or whole plant] has also been used in Malabar to treat madness (Lawler 1984).

V. cristata yielded [w/w] 0.02% laburnine acetate, a pyrrolizidine alkaloid [see **Laburnum**] (Lindström & Lüning 1969). In an alkaloid screening, it was found to contain over 0.1% alkaloids (Lüning 1967).

V. parishii [fresh whole plant] yielded 0.0026% of a new glucoside, parishin [tris[4-(β-D-glucopyranosyloxy)-benzyl]citrate], as well as 0.0018% of a glucoside which was probably an artefact of the extraction (Dahmén & Leander 1976).

V. roxburghii contains an unidentified alkaloid and a glycoside, as well as tannins, saponins, sterols, resins, fatty oils and colouring agents. The active component is thought to reside in the glycoside, and stimulates cholinergic nerves, producing an initial rise, and later fall in blood pressure (Chopra et al. 1958; Willaman & Li 1970).

V. lamellata, V. luzonica, V. merrillii, V. roeblingiana and V. sanderiana were found to contain c.0.01-0.1% alkaloids (Lüning 1967).

Vanda roxburghii is an epiphytic orchid with a leafy stem 30-60cm long, climbing. Leaves praemorse, 15.2-20.4cm, narrow, complicate, very coriaceous or fleshy, flat-keeled or terete. Flowers in a suberect raceme; peduncle 15-20cm, 6-10-flowered; flowers 3.8-5.1cm diam.; sepals 5, subequal, widely spreading, not incurved, clawed, obovate, waved, bases narrowed; petals 5, described as for sepals, yellowish-green or bluish except for the clathrate-brown nerves, margins white, lip ½ as long as sepals or more, with erect small-acute side-lobes, base usually saccate or spurred, midlobe panduriform, violet, tip dilated, truncate, 2-lobed, fleshy; disc of midlobe convex with fleshy ridges, white margins and mesial lines; spur conical; stamens and style united in a short, stout column; foot not or very shortly produced; anther 2-celled; rostellum obscure; pollinia 2, didymous, subglobose or obovoid, strap broad, short or long-geniculate, gland rather large. Ovary inferior, 1-celled, usually linear and twisted; stigma a viscid surface on the top or concave face of column, opposite the lip and below the anther. Seeds minute.

Common on mango trees; Bengal, Behar, west to Guzerat and the Concan, south to Travancore, Tenasserim and Ceylon (Hooker 1954-1961). Members of the genus in general are cultivated in pots or wooden baskets, with coarse pine bark; propagate from cuttings with 3 or more roots. Roots often grow outside of the pot to gain the air circulation they need. Most species like bright, humid conditions with winter min. 10-16°C (Banks & Perkins 2005).

VEPRIS

(Rutaceae)

Vepris ampody *H. Perr.*

Vepris lanceolata *(Lam.) G. Don.* **(V. undulata** *(Thunb.) Verdoorn et C.A. Sm.***; Toddalia lanceolata** *Lam.***)** – white ironwood, witysterhout, umZane, forest Vepris, African cubebs [the fruit]

Vepris madagascarica *(Baill.) H. Perrier* **(V. spathulata** *(Engl.) H. Perrier***; Humblotiodendron madagascaricum** *(Baill.) H. St. John***; H. spathulatum** *Engl.***; Pelea madagascarica** *Baill.***)**

V. ampody has no traditional uses that I am aware of. The trunk and root-bark of V. louisii are used in Cameroon to treat mycoses and dermatitis; it contains an antibacterial quaternary alkaloid called veprisinium salt (Ayafor et al. 1982). Another African species, V. heterophylla, is used in folk medicine as a diuretic and antipyretic; it contains furoquinoline alkaloids (Gomes et al. 1994). In Madagascar, V. madagascarica is used as a perfume due to its aniseed-scented parts [see **Pimpinella**]; the essential oil is used in preparations for teeth-cleaning in Japan and China (Billet & Favre-Bonvin 1973). V. lanceolata root is powdered and used by the Zulu to treat colic and influenza, and as an emetic. In Zanzibar, the fruits have been been used to cure spirit possession; the fruits are thrown on a fire and their fumes inhaled, in order "to throw out the devil" (Watt & Breyer-Brandwijk 1962).

V. ampody leaves and branches [combined] yielded 0.3% alkaloids, consisting of 80% *DMT*, 10% (n-nonadiene-3',6')-2-quinolone-4, 5% kokusaginine [see **Dutaillyea**], 0.5% 2,4-dimethoxy-10-methylacridan-9-one, 0.5% evoxanthine, 0.2% (n-nonanol-9')-2-quinolone-4, 0.1% (n-undecanone-10')-2-quinolone-4 and 0.001% phenylacetamide (Kan-Fan et al. 1970).

V. madagascarica leaves and twigs have yielded an essential oil containing *eugenol*, *methyleugenol*, *estragole*, p-cymene and *α-pinene* (Billet & Favre-Bonvin 1973).

Vepris ampody is from Madagascar; I have been unable to obtain a description, but see if you have any better luck – it is cited to be found in Mem. Acad. Sci. Paris, Ser. 2, lxvii. No. 3, 30 (1948).

VERATRUM

(Liliaceae)

Veratrum album *L.* – white false hellebore, European white hellebore, langwort

Veratrum viride *Aiton* **(V. eschscholtzii** *A. Gray***)** – American white hellebore, American false hellebore, green hellebore, swamp hellebore, Indian poke, puppet root, crow poison, devil's bite, tickle weed, bugbane, wolfsbane

These plants, as well as about a dozen other Veratrum spp., have been used in folk medicines in the past, but are now considered too dangerous for general use (Tamplon 1977). European shamans called V. album the 'seed of Hercules', and they used the dried root to treat madness caused by demons. The plant was also burned as a magical incense for its narcotic effect. Around 1900, mixtures of V. album and **Amanita** muscaria were popular with occult groups in Prague, Czechoslovakia, said to 'open doors to another world' (Rätsch 1992). V. album has also been used to poison knife-blades and arrows, or as a directly administered poison (Morton 1977).

V. viride was introduced to Europe from N. America in the late 19th century, and was taken into use for the same purposes as V. album – that is, as a cardiac sedative, analgesic, hypotensive, antispasmodic and mania treatment. It had also previously been in use in its native territory. The plants have also been used to treat neuralgia, pneumonia, respiratory afflictions, cholera, muscular dystrophy, rheumatism, arthritis and headache. They have been applied externally to skin disorders and intranasally to cause sneezing, and are also emetic, purgative and diaphoretic, though V. viride is less likely to cause gastric upset (Morton 1977). V. viride is used by the Cherokee as an ointment ingredient, to apply to painful areas and aching muscles (Hamel & Chiltoskey 1975).

When used externally, false hellebore should only be applied to unbroken skin (Chiej 1984). The plant can only be used safely in very small doses; as little as 1-2g powdered V. album rhizome may be fatal if ingested. The rhizome is the most potent plant part, though all parts are toxic. Overdose from internal administration can cause nausea, vomiting, burning sensation in throat and mouth, hallucinations, headache, numb extremities, breathing difficulties, salivation, dilated pupils, impaired vision, dizziness, abdominal pain, diarrhoea, cold sweats, weakness, tremors, sometimes convulsions, irregular and speeding pulse, brachycardia, hypotension, partial loss of consciousness and later paralysis and collapse. Symptoms usually disappear completely within 24 hours. In extreme cases death results from asphyxia. Some British Columbian natives say the only effective antidote for Veratrum poisoning is large amounts of salmon oil. Numbness of the mouth and nausea have even been reported from drinking water in which V. viride was growing (Bruneton 1995; Morton 1977; Tamplon 1977; Turner & Szczawinski 1991). V. californicum has long been known to induce teratogenic effects in sheep, largely due to the actions of the alkaloids cyclopamine and veratramine (Keeler 1968, 1975).

V. album rhizome has yielded 1.5% steroidal alkaloids, mainly protoveratrines A & B [the A form is more potent orally; the B form is also known as veratetrine or neoprotoveratrine], as well as veramanine, veratrosine, germerine, neogermitrine, germitetrine B, jervine, rubijervine, pseudojervine and neojerminalanine; and a glucoside, veratramarine.

V. viride contains protoveratrines A & B, veratridine, veratramine, veratrosine, germidine, germitrine, germine, cevadine, jervine, pseusojervine, rubijervine and isorubijervine (Bruneton 1995; Jacobs & Craig 1946; Kupchan & Deliwala 1953; Morton 1977; Rahman et al. 1996). Veratrine has been shown to inhibit plasma AChE (Orgell 1963a).

Veratrum viride is a leafy perennial 0.6-1.5m tall, polygamous, with a slender bulb, joining to a stem with a persistent elongated base; stems 0.5-1cm diam., pubescent. Leaves elliptic, from tubular sheathing bases (except higher up stem), 15-30 x 6-14cm, conspicuously plaited, acuminate (sometimes acute), sessile, or the lower short-petiolate. Inflorescence a paniculate raceme 0.3-1m long, the terminal raceme usually the longest, rachis pubescent, lowest branches of inflorescence subtended by leafy bracts; pedicels 1-4mm long; flowers actinomorphic; sepals and petals 3; perianth segments non-glandular, 1-1.5cm long, 3-5mm wide, acute to acuminate, base attenuate; stamens 6, attached to the very base of perianth segments. Carpels 3; ovary superior or partly inferior. Capsule 1.7-2cm long, 9-12mm diam., ovoid-lanceolate to ellipsoid, with persistent perianth; seeds yellowish to brown, lanceolate, winged, tapered to an acute apex, base oblique, 8-11mm long. Fl. Jun.-Aug.; fr. Jul.-Sep.

In bogs and wet woods, common; mountains of North Carolina, Tennessee, Virginia, West Virginia, Georgia (Radford et al. 1964).

Gather early autumn. Do not confuse with 'gentians' [Gentiana spp.; see *Endnotes*], which look similar and are not considered to be dangerously toxic (Chiej 1984). 'True' hellebores are Helleborus spp. [see *Methods of Ingestion*].

VERBENA

(Verbenaceae)

Verbena officinalis *L.* – verbena, verbenaca, vervain, veneris herba, herba sacra, holy wort, druid's weed, enchanter's plant, Juno's tears, Brittanica, pigeon's grass, pigeonwood, simpler's joy, ma bian cao

Verbena has been quite esteemed in European history. Priests of ancient Rome used bundles of the herb to sweep and purify their altars to Jupiter; they also used it in love rituals, and it was carried by the 'verbenarius' in peace negotiations. Pliny wrote that French Druids used verbena to prophesy, and that the Zoroastrian priests known as the Magi would rub the plant all over the body, to obtain all that they desired and enable them to 'cure all ills'. The Magi used elaborate rituals for the collection of the plant at the ascribed time, reminiscent of the ritual collection of mandrake root [see **Mandragora**]. The herb is said to give 'wondrous, prophetic dreams' and to act as an aphrodisiac and nerve tonic. It was also used as an ingredient in some witch's flying ointments. Ancient Germans, who also used the herb as an amulet for peace, used it to protect against the 'evil eye' and other evil influences. In magical practices, the herb is often used to effect love (Bremness 1994; Chiej 1984; Cunningham 1994; Mabey et al. ed. 1990; Pliny 1897; Rätsch 1990, 1992).

In TCM, the dried herb is used as an antibacterial, analgesic, antiinflammatory and blood coagulant (Huang 1993). It may have some antidepressant, cardiotonic and antitumour activity, and can be used to treat headache and gallstones, as well as acting as a liver tonic, emmenagogue and galactagogue. Flowering tops can be infused to treat insomnia, jaundice, urinary difficulty and cramps. A wash is good for mouth ulcers, hair and eyes; a poultice can be used for wounds and skin ulcers. Nausea and gastric upset is experienced by some people who take this herb internally. It should be avoided by pregnant women (Bremness 1994; Huang 1993; Mabey et al. ed. 1990).

On a related note, the Mojo Arawak of e. Bolivia have made use of an unidentified plant called 'marari', reported to be "similar to our verbena [Verbena officinalis]". A decoction of it was drunk by shamans when they were required to "interview the spirits". It was only used for difficult divinations, and caused excitation, insomnia and pain for up to 24 hours (Schultes 1966, 1967a).

V. officinalis contains glycosides, including verbenalin [0.244%; laxative, weak parasympathetic agent, causes uterine contractions; in frogs, acts as a CNS motor stimulant, causing stupor and convulsions, followed by paralysis, in large doses], verbenalol, verbenin, eukovoside and hastatoside; as well as *adenosine*, an unidentified alkaloid, mucilage, tannin and a small amount of essential oil (Buckingham et al. ed. 1994; Chiej 1984; Chopra et al. 1965; Harborne & Baxter ed. 1993; Huang 1993; Mabey et

al. ed. 1990; Watt & Breyer-Brandwijk 1932).

Verbena officinalis is a perennial herb; stems 30-60(-100)cm, erect, quadrangular, longitudinally ribbed, scabrid on the angles and diffusely branched. Leaves opposite or rarely on whorls of 3, +- rhombic, strigulose, the lower 4-6 x 2-4cm, petiolate, deeply incised, lyrate to 1-2-pinnatifid, the upper smaller, sessile and subentire or entire. Flowers in bracteate spikes, 10-25cm in fruit, terminal, long-pedunculate, solitary or in a very lax panicle; bracts ovate-acuminate, ciliate, up to ½ as long as calyx; calyx tubular, 5-ribbed and unequally 5-dentate; corolla hypocrateriform, weakly 2-lipped, pale pink, twice as long as calyx, with obtuse or emarginate lobes; stamens inserted at about middle of the corolla tube, included; stigma unequally 2-lobed. Ovary superior, initially 1-locular but becoming 2-4-locular by development of septa; style terminal. Ovules usually 1 in each loculus. Fruit separating at maturity into 4 nutlets; nutlets 1.5-2mm, reddish-brown, with 4-5 longitudinal ribs on the back (Tutin et al. ed. 1964-1980).

Fertile, well-drained loam, wasteground, roadsides, sunny positions (Bremness 1994); most of Europe, naturalised in Australia [all states except Western Australia] (Hnatiuk 1990); often cultivated. Gather in summer.

VINCA and CATHARANTHUS

(Apocynaceae)

Vinca major *L.* – greater periwinkle, blue periwinkle, sorcerer's violet

Vinca minor *L.* – lesser periwinkle, blue buttons, creeping myrtle, sorcerer's violet, fior di morto ['flower of death'], centòcchio ['hundred eyes'], devil's eye, flower of immortality, joy of the ground, priapisci, pervinca, vincapervinca

Catharanthus lanceus *(Boj. ex A. DC.) Pich* **(Lochnera lancea** *Boj. ex A. DC.***; Vinca lancea** *(Boj. ex A. DC.) K. Schum.***)**

Catharanthus roseus *(L.) G. Don* **(Lochnera rosea** *(L.) Reichb.***; Vinca rosea** *L.***)** – Madagascar periwinkle

In 2nd century Rome, V. minor was held to be effective against "the devil sickness and demoniacal possessions and against snakes and wild beasts". While these last few claims may be fabricated, the plant is effective against some forms of dementia due to its capacity to increase cerebral blood flow. It has been used also as an astringent and to staunch wounds (Chevallier 1996).

Vinca spp., when gathered under appropriate conditions, are used in love magic, though they have long been associated with death, and placed on children's coffins. In some areas, the trailing stems [for which the genus is named – from the Latin vincere ('to bind'), due to the tendency of the branches to wrap around supports and cover the ground] are used in basket-making. V. minor is antispasmodic, hypotensive, astringent and prevents haemorrhage, as well as improving cerebral blood flow; these properties are shared by V. major. The herbs should not be taken by pregnant women (Chiej 1984; Cunningham 1994; Polunin & Robbins 1992).

C. roseus is used medicinally in Brazil – the leaf is infused for haemorrhage and scurvy; this is also used as a mouthwash for toothache, and to heal and cleanse chronic wounds. In the West Indies, a flower infusion is used as a diabetes treatment, and a decoction is used as an eyewash. The leaves are bitter, emetic, astringent and diaphoretic. C. lanceus leaves are used in S. Africa as a bitter astringent emetic. In Madagascar, the plant is used to treat dysentery; aerial parts are galactagogue and emetic, and roots are used as a purgative vermifuge. Extracts of the plant are hypotensive, hypoglycaemic, antiviral and antitumour in effect (Morton 1977; Svoboda & Blake 1975; Tin-Wa & Farnsworth 1975).

This closely related genus, Catharanthus, enters our picture due to a possible error of sorts. In the late 1950s, scientists at Eli Lilly Co., pursuing a diabetes treatment, discovered that extracts of C. roseus showed antitumour activity. The chemicals focused on were vinblastine [vinkaleukoblastine; VLB] and vincristine [VCR], and in their sulfate forms they were marketed as Velban and Oncovin [Vincovin], respectively, and have been used in chemotherapy (Blackwell 1990). When using extracts of the plant on patients, physicians noted that some side effects of the treatment were a euphoria with pleasant hallucinations. When this news spread, there was an outbreak of periwinkle smoking in Florida, usually stated to involve C. roseus, which is common there. However, a national magazine article which brought some attention to this matter and helped spread the practice, referred to the use of a blue-flowered periwinkle ["...five teenagers disclosed that they were smoking the dried and shredded leaves of the periwinkle, a blue-blossomed plant common throughout the U.S. The smoke, the youngsters reported, made their skin tingle as though ants were crawling over it and they seem to see the world through the wrong end of a telescope."]. Flowers of C. roseus are usually pink, but never blue; V. major and V. minor flowers may be blue, purple, or white. Either the plant involved was a Vinca sp., or it was C. roseus and the error occurred in journalistic interpretation. Side effects of vinblastine and vincristine administration include an immediate reduction in white blood cell count. Exposure over time leads to itching and burning skin sensations, loss of coordination, muscle deterioration and hair loss (Emboden 1979a; Farnsworth 1969; Morton 1977). Due to this, it has been advised not to smoke C. roseus, although today some have overcome the fear and tried it with positive results (pers. comms.). Still, moderation should be advised to avoid such potential toxicity.

Leaves of V. major, and presumably of V. minor, can also be smoked, producing a hypnotic tranquillisation with anxiolysis, mild euphoria and mild perceptual distortions, lasting several hours. This was subjectively similar to a smoked sample of **Mitragyna** speciosa leaves (pers. obs.). One psychonaut ingested a tea made from 1g dry V. minor root, with fruit juice, and found it to act as a pleasant and effective euphoriant and nöotropic (theobromus pers. comm.).

As a note of interest, in the mid-1940's in Jamaica, one could be arrested for smoking periwinkle, which was called 'ram-goat rationale' (Chevannes 1994), suggesting that the psychoactive effects of the plant were known there and made use of. The actual species of periwinkle [ie. Vinca spp. or Catharanthus spp.] is not mentioned, though it was probably in reference to C. roseus.

Periwinkles contain a wide array of indole alkaloids in all parts, many with physiological and psychoactive effects; they often act as hypotensive tranquillisers, and may increase cerebral blood flow.

V. major aerial parts yielded c.0.79% alkaloids, including *vincamine*, vincine, 0.022% reserpinine, vincamajoreine, 0.0013% vincamajoridine [akuammine], 0.00065% vincamedine, 0.003% vincamajine, 0.0005% vincanovine, 0.026% majdine, 0.0028% majorine, 0.0029% majoridine, 0.0002% majvinine, 0.0004% majovine, perivincine, 10-MeO-vellosimine and lochvinerine (Banerji & Chakrabarty 1974, 1977; Kaul & Trojanek 1966).

V. minor aerial parts have yielded 0.3-1% alkaloids, 10% of which may be *vincamine*, as well as c.30 other indole alkaloids (Bruneton 1995), including quebrachamine, N-methylquebrachamine, vincadine, vincaminoreine, vincaminoridine, vincaminorine, N-methylaspidospermidine, 1,2-dehydroaspidospermidine, minovine, minovincine, 16-MeO-minovincine, 10-oxo-minovincine, minovincinine, 12-epi-minovincinine, 16-MeO-minovincinine, vincadifformine and 16-MeO-vincadifformine (Ganzinger & Hesse 1976). The plant inhibits human plasma AChE (Orgell 1963b). Total alkaloids from this plant have been reported to have a *reserpine*-like activity (Verzár-Petri 1972).

V. sardoa aerial parts yielded 0.018% N(1)-methyl-14,15-didehydro-12-MeO-aspidofractinine, 0.009% N(1)-formyl-14,15-didehydroaspidofractinine, 0.007% venalstonine, 0.006% conoflorine, 0.0036% N(1)-formyl-14,15-didehydro-12-OH-aspidofractinine and 0.002% N(1)-methyl-14,15-didehydro-aspidofractinine. Roots yielded norfluorocurarine, akuammigine, carapanaubine, majdine, isomajdine, rauvoxinine, ent-N(1)-methyl-14,15-didehydroaspidospermidine, N(1)-methyl-14,15-didehydrotuboxenine, and aspidofractinine derivatives (Nicoletti et al. 1998).

C. lanceus leaf yielded 1.36% crude bases, containing *yohimbine* as a major alkaloid [0.0029-0.0074%], as well as perivine [0.008-0.0092%; CNS depressant], *ajmalicine*, leurosine [0.00047%; adrenergic blocker], lochnerinine, vindolinine [CNS stimulant], vindoline [0.00004-0.00016%; CNS stimulant & depressant], catharanthine [CNS depressant] and 3,4-dimethoxy-phenylacetamide [CNS-depressant]. Roots have yielded 0.2-2.127% crude alkaloids, containing *yohimbine* [0.002%], *ajmalicine* [0.0196%], tetrahydroalstonine [weak muscle relaxant], pericalline [0.0028%], perimivine [0.0002%], lanceine and cathalanceine [0.0002%]. Stems have yielded 0.1-0.15% crude alkaloids. Also isolated from the plant have been pericalline [convulsant], ammocalline, vincoline, vinosidine, catharine, pericyclivine, periformyline, horhammericine, horhammerinine and cathanneine [cathovaline] (Blomster et al. 1964b; Maloney et al. 1968; Svoboda & Blake 1975; Tin-Wa & Farnsworth 1975).

C. roseus leaf has yielded catharanthine, catharosine, catharicine, catharine, cavincine, vincarodine, vincolidine, vincoline [CNS depressant], vindoline, vindolinine, vindolicine, vindolidine, desacetyl-vindoline, vindosidine, vinsedicine, vinsedine, vindorosine, vincristine, vincaleukoblastine [VLB], desacetyl-VLB [CNS depressant], vincathicine [CNS depressant], vincamicine, vinaphamine, vinaspine, vinaphamine, sitsirikine [CNS depressant, vasodilator], isositsirikine, dihydrositsirikine, perivine, perividine, perosine, perimivine, *mitraphylline*, lochnericine, lochneridine, lochnerinine, lochrovicine [CNS depressant, weak autonomic effects], lochrovidine [CNS depressant], lochrovine, carosine, carosidine, leurosine, isoleurosine, leurosidine [CNS depressant & stimulant], leurocristine [CNS depressant], neoleurocristine [CNS depressant], neoleurosidine, pleurosine, rovidine, *adenosine* and 0.00022% *norharman*. Roots yielded 1.18-1.22% alkaloids. The plant has also yielded *ajmalicine*, akkuamine, tetrahydroalstonine, *reserpine*, serpentine and lochnerine [CNS depressant & stimulant] (Chevallier 1996; Morton 1977; Rahman et al. 1985; Svoboda & Blake 1975). Leaf and stem of plants from Brisbane [Queensland, Australia], harvested in April, tested strongly-positive for alkaloids (Webb 1949).

Vinca major is a low, creeping dwarf shrub or herbaceous perennial, with usually trailing vegetative shoots, stems up to 100cm, ascending

in the lower part, then arching or procumbent, overwintering. Leaves opposite, 2.5-9 x 2-6cm, mostly ovate or broadly ovate, rarely lanceolate, evergreen, deep green, usually glabrous, margins ciliate with hairs 0.1-1mm long. Flowers solitary in leaf-axils, on ascending flowering stems up to 30cm; pedicels shorter than the subtending leaves; calyx lobes 7-17mm long, very narrowly triangular, margins densely ciliate with hairs 0.5-1mm; corolla hypocrateriform, usually bluish-purple, the tube gradually widened, 12-15mm long, with a zone of hairs above insertion of stamens, and a low ridge connecting lobes at mouth, lobes obliquely truncate, as long as tube, overlapping to the left in bud, limb 30-50mm diam.; stamens inserted ½ way up corolla tube; filaments bent abruptly at base; anthers introrse, closely surrounding the stigma, with connective expanded above into a flap-like appendage. Ovary superior; carpels 2, usually free, united by a single style above, with 4-8 ovules, alternating with 2 disc scales. Fruit of (1-)2 fusiform follicles, patent, usually opening by ventral suture; seeds glabrous.

In woods, scrub, hedges, or other shady places; west and central Mediterranean region, widely naturalised and cultivated elsewhere (Tutin et al. ed. 1964-1980).

Catharanthus roseus is a downy herb or small shrub; branches terete. Leaves opposite, evergreen, coriaceous, elliptic, obtuse, mucronate; petioles bidentate or bistipulate at base. Flowers axillary, solitary, or twin, sessile, bright crimson to peach- or rose-coloured (some varieties white, or white with a purple circle), paler on underside, with a dark purple eye; calyx 5-parted, segments subulate, ciliate; corolla salver-shaped, 5-lobed, segments nearly equal-sided, obovate, mucronate, throat bearded, tube long and slender, clavate at top with 5 tubercles; stamens enclosed, conniving over stigma; anthers mucronate, not membranous at top, sessile. Hypogynous glands 2, elongated like the ovaria; stigma capitate, marginate, bearded at top, furnished with a cup-shaped membrane below, which sheaths the upper part of the style. Follicles twin, small, terete, glabrous, 2-celled, dehiscing inside; dissepiment double, taking its rise from the suture, which is plaited inwards; seeds 16-20 in each follicle, attached longitudinally to each side of dissepiment, small, ovate-acuminate above, grooved and rugged from sharp tubercles on one side, smooth on other side.

In tropics; appears to be native to Madagascar (Stearn 1966).

VIROLA

(Myristicaceae)

Virola bicuhyba *(Schott) Warburg*

Virola calophylla *Warburg* **(Myristica calophylla** *Spruce***)** – paricà, yakee, ajua apumpo, ardilla paparahua, huapa, anya huapa, pucuna huapa, huapa jandia, sacha, shiquillo, suni panga huapa, a-re-dje, iheara, tegidewe, cumala blanca, yato, yea-ga-seii

Virola calophylloidea *Markgraf* – ya-kee, ya-to, ko-ga, rase-jiameti, cumala, bojorique

Virola duckei *A.C. Sm.* – angus caspi, huachig caspi, anya huapa, huapa, huapa blanca, ardilla paparahua, sacha paparahua, huapa urcu

Virola elongata *(Benth.) Warburg* **(V. cuspidata** *(Spruce ex Benth.) Warburg***; Myristica elongata** *Benth.***)** – huapa, anya huapa, pucuna huapa, calun-calun, ucufe-ey, ra-se-ne-mee, tsu-nem, ko-de-ko, oo-koó-na, yakoana, cumala blanca, cumala caspi

Virola loretensis *A.C. Smith* **(V. villosa** *Ducke***)**

Virola multinervia *Ducke*

Virola pavonis *(A. DC.) A.C. Smith* **(V. venosa var. pavonis** *Warb.***; Myristica pavonis** *A. DC.***)** – anya huapa, puliu huapa, pucuna huapa, cedro ajua, huachig caspi, ko-do

Virola peruviana *(A. DC.) Warburg* **(Myristica peruviana** *A. DC.***)** – nankitawe, tegidewe, cumala blanca, ya-kee

Virola rufula *(Mart. ex A. DC.) Warburg*

Virola sebifera *Aublet* **(V. mocoa** *Warb.***; V. peruviana var. tomentosa** *Warb.***; V. venezuelensis** *Warb.***; Myristica mocoa** *A. DC.***)** – wircaweiyek, orika-bai-yek, paissam, cuajo negro, camaticaro, cacao del monte

Virola surinamensis *(Rol.) Warburg* – oo-koó-na, kur-du-ko, ucuuba branca, cumala blanca, cumala colorada, caupuri

Virola theiodora *(Spruce ex Benth.) Warburg* – oo-koó-na, ko'-ke-ko, gua-roo'-ta-ta, ka-se-ree-mee'-hoog-nou, bicuhyba cheirosa

Trees of the genus Virola were only relatively recently discovered to be widely used for entheogenic purposes in the Amazon; many are used medicinally, to treat skin disorders, malaria and other complaints. Several species, especially V. elongata and V. theiodora are used either as a snuff [usually blown forcefully into the nasal cavities by another, through a long, slender tube], notably by the Yanomamo [who also snuff **Anadenanthera** sp.], or as an orally-ingested pill. In some tribes the snuffs are only used by shamans to enter a healing trance, or else used by everyone following a death in the tribe, in ceremonial festivals, or before going on a hunt. Others allow use by all males older than 13-14 years of age. Some use it only occasionally, while others [such as the Yanomamo] use it almost recreationally, snuffing all day, most days. Usually, it is snuffed in very large amounts to reach the full point of 'ekstasis' and communion with the world of the 'hekula' spirits – and in such large amounts that at least one death has been reported, that of a Puinave shaman who died whilst under the influence [which may have been due to suffocation, from the snuff entering the lungs] (Brewer-Carias & Steyermark 1976; Chagnon et al. 1971; Lizot 1985; Prance 1970, 1972; Prance et al. 1977; Schultes 1955a; Schultes & Hofmann 1980, 1992; Schultes & Holmstedt 1971; Seitz 1967; Uscategui 1959).

Bark sap of V. calophylla is made into a snuff ['yakee'] by natives of the Colombian Amazon, as is bark sap from V. calophylloidea in the Vaupes. More than 1 tsp may be snuffed at a time. V. elongata is used by the Maku and possibly the Barasana of Colombia, as well as the Paumari of Rio Purús, Brazil. The Waiká Yanomamo of n.w. Brazil and Venezuela prepare a snuff, called 'epéna' ['semen of the sun'], 'ebena' or 'nyakwana', from bark sap [and sometimes leaves] of V. theiodora; they also use it to make dart poisons. Apparently, when they run out of snuff, they may scrape resin from their darts and snuff that, for the same effect. The Barasana, Makuna, Taiwano, Kabuyari, Kuripako and others also make a snuff from this species. V. sebifera was once used in Venezuela as an entheogen, shamans smoking the bark when curing. V. bicuhyba seed is said to be 'narcotic', and acts as a 'brain stimulant', reviving memory and intelligence. V. peruviana is possibly used as an entheogen in Colombia, and has tested positive for alkaloids; V. rufula might also be so used (Davis 1996; Macrae & Towers 1984a; Prance 1970, 1972; Prance et al. 1977; Schultes 1955a; Schultes & Holmstedt 1971; Schultes & Raffauf 1990).

The Witoto of the Peruvian Amazon once consumed resin from V. theiodora in oral pill-form, to "see and converse with the little people". It appears this use is no longer practised, though its methods of preparation are still known. From 3-6 of the coffee bean-sized pellets were reportedly taken; effects are said to manifest within 5 mins, lasting about 2 hrs, with 'visual hallucinations' occurring. Sometimes more is taken after the effect wears off. It was used mostly by shamans, and occasionally by small groups of people for purposes of divination, or 'studying' from the spirits (Schultes 1969b). The Bora preferred to use V. elongata, but also used V. loretensis, V. pavonis or V. surinamensis to prepare the pills (Schultes & Holmstedt 1971; Schultes et al. 1977a).

As 'caupuri', V. surinamensis has been used as an ayahuasca additive [see **Banisteriopsis**], and may also be taken under diet, as a plant teacher (Luna 1984). Bear & Vasquez (2000) mention the use of a plant called 'cahuapuri' as a plant teacher; this might also represent V. surinamensis. When taken after dieting with Canavillesia spp. [see *Methods of Ingestion*], Vasquez reported that it "can give one mastery over the mind, and the power to heal". He prepared it by grinding the fresh bark, and infusing it in water overnight; the next day the liquid was strained and drunk (Bear & Vasquez 2000). Some bees are known to produce intoxicating honey after feeding on the nectar of V. surinamensis (Groark 1996).

The Quichua use Virola spp. sap to treat caries, thrush and skin infections. The Quijos Quichua recognise the entheogenic properties of V. duckei sap (Bennett & Alarcon 1994).

Orally-active pills are prepared from the bark as follows – best trees are selected by slashing and testing a small strip of bark. It should have an ample cambial layer, bitter taste and musty odour (Schultes et al. 1977a). Collections are made in the early morning, when alkaloid content is highest. Strips of the bark c.75cm long are cut from the lower portion of the trunk; sometimes, it is stripped from the entire circumference of the tree, then the tree is felled and the upper bark stripped. Inner bark exudes a clear resinous sap when freshly cut – this later congeals and turns a deep reddish-brown (Schultes & Raffauf 1990; Schultes & Swain 1976). The inner part of the freshly stripped bark is rasped; the tissue obtained is rolled into balls and squeezed into water, which is boiled for 5-6 hrs with careful stirring until it is a thick, sticky syrup; or, it is reduced to a simmer for 1 hour or so. Some steep the leaves of a fern [Anemia sp.] in the water used for this previous step, or add the juice of the crushed stems of Philodendron nervosum. Some also add bark of Rinorea racemosa [see also *Methods of Ingestion*], or an unidentified lichen to the resin. The Witoto reduce the bark of Gustavia poeppigiana to ashes, and rinse them with cool water until no more cloudiness leaches out; this water is boiled down to a greyish residue, or 'salt' ['le-sa']. The Virola resin is rolled into coffee bean-sized balls, and rubbed in the 'salt', ready for consumption (McKenna et al. 1984b; Schultes 1969b). This is similar to the alchemical preparation of some tobacco-pastes [see **Nicotiana**], and may contribute to activity. Other plants are also used in making the 'salt' – Eschweilera itayensis [bark with some adhering wood], **Spathiphyllum** cannaefolium [whole plant], Geonoma juruana [trunk & leaves], [tentatively identified] a Carludovica sp. [see *Endnotes*] or a Sphaeradenia sp., **Theobroma** subincanum [leaves and twigs] and a Bactris sp. [trunk & leaves]. Often, pellets are only coated with the 'salt' if they are to be kept for later – otherwise, they are used immediately. They are said to keep their potency for about 2 months (Schultes & Raffauf 1990; Schultes & Swain 1976).

Virola snuffs are prepared in a similar manner to oral pills, the main difference being that the paste, once boiled down, is sun-dried, finely pulverised and mixed 1:1 with the ashes of either Elizabetha princeps bark, or

Theobroma subincanum; powdered dried leaves of **Justicia** pectoralis var. stenophylla may also be added; also, no salts are added. Sometimes, the bark scrapings themselves are simply dried over a fire and powdered and sifted for use, alone or with the above admixtures. Some build a fire at the place of harvesting, and immediately heat the bark strips over the fire, collecting the resin that oozes out. This method is sometimes used to obtain resin with which to coat the tips of hunting arrows. The snuff is said to lose potency rapidly, even when stored in a tight container, and as such, it is prepared often, and only in small amounts. A shamanic dose of such snuff is said to be roughly 1 heaped tsp, taken in 2-3 inhalations at intervals of 15-20 minutes (Brewer-Carias & Steyermark 1976; Prance 1970, 1972; Prance et al. 1977; Schultes 1955a, 1967b; Schultes & Raffauf 1990; Seitz 1967).

It is not surprising to note [given the phytochemistry outlined below] that barks and the concentrated saps of some Virola spp. have been successfully used in ayahuasca analogues (pers. comms.).

Virola spp. seem to be very variable in their alkaloid content, and while one sample of a given species may yield large amounts of alkaloids, another may yield much less or none at all.

V. calophylla flowers and shoots yielded 0.193% alkaloids [96% *DMT*, 4% *N-methyltryptamine* (NMT)]; fruit and seeds 0.0185% *DMT* and traces of *NMT*; leaves 0.155% [same ratio as flowers and shoots]; bark 0.009-0.056% [91-100% *DMT*, 0-9% *5-MeO-DMT*], as well as *tryptamine*, 2-methyl-THβC (Holmstedt et al. 1980; McKenna et al. 1984b) and 2-methyl-6-MeO-THβC [2-methyl-*pinoline*]; and root 0.001% [87% *DMT*, 13% *5-MeO-DMT*] (Agurell et al. 1969a; Cassady et al. 1971; Shulgin & Shulgin 1997). Leaves have also yielded otobaene, hydroxyotobain, 2',4'-dihydroxy-4,6'-dimethoxydihydrochalcone, vanillin and sitosterol; bark has also yielded *safrole* and methylparaben (Constanza et al. 1999).

V. calophylloidea leaves have yielded 0.098% *DMT*; bark yielded 0.0075% alkaloids [50% *DMT*, 45% *5-MeO-DMT*] (Holmstedt et al. 1980); trunk wood contains neolignans, flavonoids and steroids (Martinez & Cuca 1987).

V. elongata bark phloem has yielded *tryptamine*, *DMT*, *NMT*, *5-MeO-DMT*, 5-MeO-*NMT* and 2-methyl-THβC; 2-methyl-*pinoline* has also been found in the resin. Whole bark yielded 0.023% *5-MeO-DMT* and traces of *NMT* in one sample; another contained 0.0102% *NMT* and 0.0063% *DMT*. Leaves have yielded 0.017-0.019% *DMT* and traces of *NMT* (Holmstedt et al. 1980; McKenna et al. 1984b); stem and leaf together [as V. cuspidata] yielded 6-MeO-1,2,3,4-*tetrahydroharman* [*adrenoglomerulotropin*] as the major alkaloid, with lesser amounts of *6-MeO-harmalan* and 6-MeO-*harman* [isoharmine], as well as otabaene and hydroxyotobain. Bark has also yielded the lignans [0.016% combined] virolongin, eusiderin, sesartemin, epi-sesartemin, dihydrosesartemin, yangambin, epi-yangambin and β-dihydroyangambin; the stilbenes 3,4',5-trimethoxy-trans-stilbene and 3,4',5-trimethoxy-cis-stilbene; β-sitosterol; and unidentified aromatic compounds (Cassady et al. 1971; Macrae & Towers 1984a; Shulgin & Shulgin 1997). Snuff made from the tree has yielded 0.15-2% alkaloids, consisting of 7-10% *DMT*, 90-93% *NMT*, and, in one sample, entirely *5-MeO-DMT* (Chagnon et al. 1971; McKenna et al. 1984b). Human bioassay of 1.5-2g of the oral-paste [which contained 1.57% *5-MeO-DMT*, and traces of *NMT*] resulted in effects being felt 10 minutes after swallowing, consisting of "a strong burning sensation in the mouth and throat, which quickly developed into a feeling of numbness in the lips, tongue and throat. Swallowing was difficult and breathing was impaired. The numbness gradually spread throughout the body, with a tingling sensation in the extremities...[body] felt chilled...heavy and inert...breathing was irregular and shallow...experienced enhanced acuity of hearing...but otherwise no perceptual changes." Symptoms subsided over 45 minutes, except for the chilling sensation, followed by drowsiness, and a light, brief sleep (McKenna et al. 1984b). Assays in mice [i.p.] showed the non-alkaloidal extract [20-320mg/kg] to have greater effects on motor activity [due to the bioactive lignans] than the alkaloid fraction [causing depression and stupor], relative to the weight of the source bark for each. In terms of actual potency, the alkaloid fraction [1-15mg/kg] was similarly potent, but instead caused slight hyperactivity at the higher doses tested (Macrae & Towers 1984a).

V. multinervia root yielded 0.001% alkaloids [59% *5-MeO-DMT*, 41% *DMT*], and bark yielded 0.001% *DMT* (Agurell et al. 1969a), though others have found no alkaloids in the bark (McKenna et al. 1984b); the wood has yielded sitosterol, stigmasterol, virolane and virolanol (Filho et al. 1973).

V. pavonis leaves and twigs from one sample tested positive for the presence of *DMT* and *NMT*, though this collection was based on sterile material, and identification was probably in error, as all other samples tested negative for alkaloids. An oral-paste sample made from V. pavonis was devoid of alkaloids, and showed no activity in a human bioassay of 10g (McKenna et al. 1984b).

V. peruviana bark [fresh] has yielded 0.0175% *5-MeO-DMT*, *5-MeO-tryptamine*, *DMT*, 2-methyl-*pinoline*, 1,2-dimethyl-*pinoline*, 0.0072% phytosterols [β-sitosterol, stigmasterol, campesterol], 0.0039% lirioresinol-A dimethyl ether, 0.0046% lirioresinol-B dimethyl ether, myoinositol, and n-alkanols [octacosanol, triacontanol, dotriacontanol]; paste prepared from the bark has yielded 0.028% alkaloids [99% *5-MeO-DMT*, traces of the THβC's] (Holmstedt et al 1980; Lai et al. 1973a, 1973b).

V. rufula has a high content of *5-MeO-DMT*, also containing 2-methyl-*pinoline*. Bark has yielded 0.2% alkaloids [95% *5-MeO-DMT*, 4% *DMT*]; root has yielded 0.144% alkaloids [94% *5-MeO-DMT*, 4% 5-MeO-*NMT*, 1% *DMT*]; leaves 0.098% [94% *DMT*, 6% *NMT*] (Agurell et al. 1968a, 1969a); the plant has also yielded 6-MeO-THβC (Shulgin & Shulgin 1997). The snuff made from the bark resin yielded c.8% alkaloids [*5-MeO-DMT*, *DMT* and trace other tryptamines] (Schultes 1969b).

V. sebifera bark has yielded 0.018% *5-MeO-DMT*, 0.0078-0.014% *DMT*, *DMT* N-oxide, *NMT*, N-methyl-N-formyltryptamine, N-methyl-N-acetyltryptamine and 2-methyl-THβC, as well as β-sitosterol, and complex mixtures of phenolic [0.014%] and acidic [0.008%] compounds. Leaves have yielded traces of *NMT*. A sample of an orally-active paste from the bark yielded 1.88% alkaloids [70% *5-MeO-DMT*, 20% *DMT* and 10% *NMT*]. A human ingestion of the bark resin nearly 150 years ago [dose and method of ingestion not noted] resulted in vivid dreams, confusion and insomnia lasting 5 days. A more recent human bioassay of 3-4g by Dennis McKenna resulted in "hypnagogic imagery behind closed eyelids...easily disrupted by external stimuli" (Corothie & Nakano 1969; Kawanishi et al. 1985; McKenna et al. 1984b; Schultes & Holmstedt 1971; Shulgin & Shulgin 1997).

V. surinamensis leaf has yielded the neolignans virolin and surinamensin (Macrae & Towers 1984a; Zacchino 1994). The plant has in one test been found to contain no alkaloids (Holmstedt et al. 1980), but considering its reported usage, it seems likely that some specimens will yield tryptamines.

V. theiodora bark has yielded 0.25% alkaloids [52% *DMT*, 43% *5-MeO-DMT*, 4% 2-methyl-*pinoline*, 1% *NMT*] – another study found 0.065% [95% *5-MeO-DMT*, 5% *DMT*]; flowers and shoots 0.47% [93% *DMT*, 7% *NMT*]; leaves 0.044% *DMT*, with traces of 2-methyl-THβC; root 0.017% [62% 6-MeO-*DMT*, 22% *DMT*, 15% 5-MeO-*NMT*] (Agurell et al. 1968a, 1969a; Holmstedt et al. 1980; Schultes & Hofmann 1980); the plant has also yielded *pinoline* and 2-methyl-*pinoline* (Shulgin & Shulgin 1997). Snuff prepared from it has yielded 0.715-11% tryptamines, mostly [72-88%] *5-MeO-DMT*, with 11-20% *DMT*, 0-2% *NMT*, 0-4% 2-methyl-THβC and 0-2% 2-methyl-*pinoline* (Agurell et al. 1969a).

V. venosa root yielded 0.001% *5-MeO-DMT*; leaves yielded 0.001% *DMT* (Agurell et al. 1969a).

V. carinata, V. divergens and V. melinonii also contain trace amounts of *5-MeO-DMT* (Holmstedt et al. 1980).

Snuffs made from unidentified Virola spp. have yielded 0.038-1.97% alkaloids, comprised of 83-100% *5-MeO-DMT* and 0-17% *DMT*. An oral paste sample, also from an unidentified source Virola sp., yielded 1.1% alkaloids, comprised of 86% *NMT*, 14% *DMT*, and traces of 2 β-carbolines; it showed no activity in human bioassays of 5-10g (McKenna et al. 1984b). Yanomamo dart poison made from bark sap of a Virola sp. yielded c.8% *5-MeO-DMT* in one analysis; each dart held about 12mg of the alkaloid (Galeffi et al. 1983). Needless to say, an intramuscular injection of large amounts of *5-MeO-DMT* would stun a small animal rather easily!

A bioassay of concentrated bark resin, obtained from a presumed Virola sp. known as 'cumala' [courtesy of Boris], resulted in mild psychoactivity. The sweetish but slightly bitter resin [several grams] was taken orally, held under the tongue and between lips and gums until dissolving, with the juice then swallowed. Subjectively, the effects consisted of relaxation and mild enhancement of the senses, lasting 2-3 hours (pers. obs.). Similar effects have been observed by others who bioassayed the same material (pers. comms.).

Though it is known that these tryptamines can be absorbed intranasally and produce an entheogenic effect, the mode of action of the oral pills has still not been adequately explained. However, the recent finding by Jonathan Ott that *5-MeO-DMT* is orally [and especially sublingually] active [see *Chemical Index*] casts some light on the matter. Of *5-MeO-DMT* and *DMT*, the major active principles, the latter is not active orally without an MAOI, although they have both been shown to have some low level in-vitro MAOI activity of their own. Any of the β-carbolines with MAOI activity are only present in very small amounts in these plants. The suggestion has been raised that lignans from the bark resin may contribute to the activity of the tryptamines, but they only show low level non-specific MAOI activity at high doses. The lignans, or other non-alkaloidal constituents, may also act as antioxidants, resulting in less molecular oxygen being available for metabolism of the tryptamines in peripheral tissues. Incidentally, MAOI screening [in-vitro rat liver] of oral pastes showed equivalent activity to 'analogues' consisting of the tryptamine constituents alone (McKenna et al. 1984b). Some experiments by western researchers (eg. McKenna 1993; McKenna et al. 1984b) have yielded no discernable activity. Perhaps the samples were from weak sources? Perhaps their informants misled them regarding proper dosage? Perhaps the other plants reported to be incorporated are vital to produce the full activity? Perhaps the indigenous users consumed other substances in their diet that exert an MAOI-effect, or even have naturally low MAO levels as a genetic trait [leading them to require a smaller dose]? Or perhaps, and more likely,

they took the pills sublingually rather than swallowing them, for greater absorption of *5-MeO-DMT*? Perhaps the tryptamines are not really the sole active constituents at all, and the lignans are major contributors to the activity of the pills? As stated above, the lignans of V. elongata bark have been shown to act as behavioural and motor depressants in mice, when administered i.p. (Macrae & Towers 1984a), though this would not seem to explain the reputed 'entheogenic' activity.

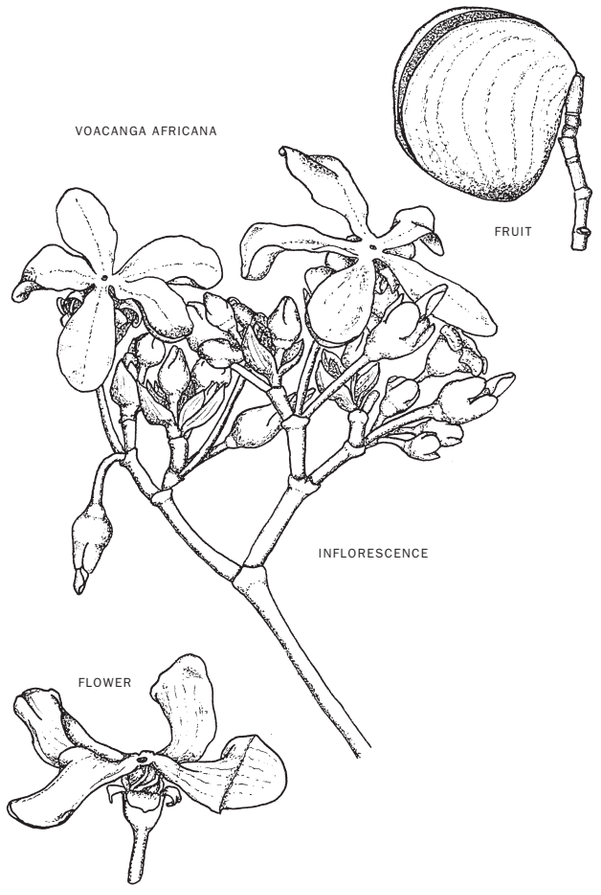
Ultimately, the most likely explanation [as stated above], in light of the sublingual activity of *5-MeO-DMT*, would appear to be that the 'oral pills' were intended to be taken sublingually, rather than swallowed, and that *5-MeO-DMT* is indeed the major psychoactive component of these preparations (pers. obs.). I later learnt that Ott had reached the same conclusion, discussed in Ott (2001c).

Virola theiodora is a slender tree, 7.6-23m; trunk cylindrical, up to 45cm diameter; bark smooth, mottled brown with grey patches; branchlets slightly red-brown tomentellous, becoming glabrous. Leaves firm-papyraceous, sometimes thick-chartaceous, often sparsely glandular-punctate, oblong to broadly ovate, basally obtuse to cordate, apex long-acuminate, margin usually sinuate, 9-35cm x 4-12cm, upper surface glabrous, dark green, nitid, underside sparsely stellate-puberulent, secondary veins 9-20, usually very prominent, ascending and arcuate; petiole subterete, most 4-15cm long, often brown-tomentellous. Staminate inflorescences many-flowered, paniculate, usually shorter than leaves, up to c.15cm, usually shorter, often brown- golden-brown-tomentellous, usually becoming glabrous; bracts 2.5cm long, deciduous. Pistillate inflorescences shorter. Staminate flowers strongly pungent, single or in clusters of 2-10; pedicel c.2mm long; perianth thin, puberulent, infundibuliform, 1.5-2.5mm long, subacutely lobed c.¼ of its length; androecium 2mm long; filament column thick, 0.5-0.8mm long; anthers 3(-5), 1-1.7mm long, usually connate, apiculate. Fruit c.5-8 per inflorescence or less, subglobose, 1-2cm long, 8-15mm diam., usually slightly apiculate, glabrescent when mature; pedicels 3-4.5mm long; aril membranaceous, laciniate c.½ of its length.

In well-drained forests. Mainly in Rio Negro Basin, w. Amazonian Brazil and Colombia; possibly also in adjacent Peru and Venezuela (Schultes & Hofmann 1980). Some botanists believe that this species is synonymous with V. elongata and V. calophylla, with V. elongata being the accepted name under this revision (McKenna et al. 1984b), and this should of course be borne in mind when considering their chemistry.

VOACANGA

(Apocynaceae)



Voacanga africana *Stapf* **(V. angolensis** *Stapf ex Hiern***; V. angustifolia** *K. Schum.***; V. bequaerti** *De Wild.***; V. boehmii** *K. Schum.***; V. eketensis** *Wernh.***; V. glaberrima** *Wernh.***; V. glabra** *K. Schum.***; V. schweinfurthii** *Stapf***; V. schweinfurthii var. parviflora** *K. Schum.***; V. schweinfurthii var. puberula** *(K. Schum.) Pichon***)** – o-bonawa, kongkong, pete pete, sulaberekilo ['monkey's testicles'], kombrocina, mokboto, mboke, boni, namanti, piegba, umdwedwe, epanda [many other regional names]

Voacanga bracteata *Stapf* **(V. bracteata var. lanceolata** *Stapf***; V. diplochlamys** *K. Schum***; V. micrantha** *Pichon***; V. talbotii** *Wernh.***)** – akbapoto, boni, bekapu, buanga, muinya, katongo, kalenge kamume, langure, kakapempe, ebangabanga lo lowe [many other regional names]

Voacanga grandifolia *(Miq.) Rolfe* **(V. papuana** *(F. von Mueller) K. Schum.***; V. papuana** *(F. von Mueller) Boerlage***; Orchipeda papuana** *F. von Mueller***; Pootia grandifolia** *Miq.***)**

Voacanga megacarpa *Merr.*

Voacanga thouarsii *Roem. et Schult.* **(V. dregei** *E. Mey.***; V. obtusa** *K. Schum.***; V. thouarsii var. dregei** *(E. Mey.) Pichon***; V. thouarsii var. obtusa** *(K. Schum.) Pichon***; Annularia natalensis** *Hochst.***; Cyclostigma natalense** *(Hochst.) Hochst.***; Orchipeda dregei** *(E. Mey.) Scott-Elliot***; O. thouarsii** *(Roem. et Schult.) Baron***; Piptolaena dregei** *(E. Mey.) DC.***; Tabernaemontana thouarsii** *(Roem. et Schult.) Palacky***)** – bu lukun, knubwobwoyi, kokiyar birii ['**Strychnos** of the monkey'], kakope, kompoure, gegbwema, papando, kivubavuba, lujiya, dumba, mabingu, muhanda, entoma, nkahlo wa tsovo [many other regional names]

These plants, and others of the genus, contain a milky latex used as glue, and indole alkaloids related to those found in **Tabernanthe** and **Tabernaemontana**. V. africana and V. thouarsii are similarly used in central Africa by hunters, drummers and shamans as a stimulant and heart tonic, to give extra endurance and alertness. Bark of V. bracteata is also reportedly used in Gabon to 'get high'. V. africana is used as a magical cleansing plant for the home in s. Nigeria. In Senegal, its latex is applied to wounds, as it is to tooth caries in Nigeria. In Senegal, a decoction of the leaf is considered a strengthening panacea, and relieves fatigue and shortness of breath. Senegalese women use a root decoction to avoid premature childbirth, or to treat painful hernias. In Tanganyika, root or bark decoctions are used to treat painful menstruation and heart troubles. In the Congo, the plant is used to relieve heart troubles and blennorrhoea, as well as being used externally on skin conditions and fungal infections. In the Ivory Coast, a lotion of the plant treats convulsions in infants; leaf sap is given as nose drops to treat insanity; and a leaf decoction is given externally for leprosy, or by enema for diarrhoea. V. thouarsii bark is used to make hunting nets in e. Africa, and its latex is applied to toothache in Sierra Leone. The latex is said to be very dangerous to bring into contact with the eyes or skin. In Mali, leaves and roots are also decocted and drunk, or bathed in, to combat fatigue and weakness, similarly to V. africana. In Liberia, the ripe seeds of V. thouarsii are scattered on the ground of rice crops to deter wild pigs. The Kru of the Ivory Coast regard an unidentified Voacanga sp. as a protective tree for children, who gain its protection by being bathed in a leaf-macerate every morning until old enough to walk (Bisset 1985b; Burkill 1985-1997; De Smet 1996; Ott 1993).

Seeds of Voacanga spp. [usually V. africana or V. thouarsii] have been used in Europe for their high tabersonine content; the extracted tabersonine is used as a precursor for *vincamine*, which is used commercially to treat various neural deficiencies in the elderly [see *Chemical Index*] (Bisset 1985a).

V. africana seeds have been used by western psychonauts as a mild **Tabernanthe**-like stimulant or mild entheogen, with c.50g ground seeds representing a dose for some people (pers. comms.). Others report that as little as c.7g of ground seeds may be sufficient, if taken in a dark, quiet room, lying down with no distractions and 'clear intent' (friendly pers. comm.). There appears to be a very variable response to these seeds in humans, and some find the experience quite unpleasant, with feelings of mild toxicity lasting up to several days afterwards (pers. comms.). It is suggested, as with **Corynanthe**, that blood-sugar levels be kept high to minimise unpleasant effects (Torsten pers. comm.). Antioxidants would probably also prove beneficial. One psychonaut ingested 20 crushed and encapsulated V. africana seeds 1 hour before eating dried **Psilocybe** mushrooms, on several occasions; the seeds were reported to greatly potentiate the mushrooms (Hoodoo pers. comm.). I have used an alcohol tincture of V. africana root bark in doses equivalent to c.3g root bark, and experienced mild and long-lasting stimulation with no negative side-effects (pers. obs.).

In animal studies, the total root bark alkaloids show CNS-depressant, hypotensive, cardiotonic and spasmolytic activities; they have been stated to be "only slightly toxic and on chronic administration they are well tolerated and there is no accumulation" (Bisset 1985a). The seeds are suspected of being neurotoxic, but no formal studies have been made. The minor alkaloids from V. africana seeds might be responsible for toxicity (pers.

comms.). Tabersonine [the major seed alkaloid] is a *reserpine*-like hypotensive, and has a spasmolytic action on intestinal smooth-muscle; it is said to be "only slightly toxic" (Bisset 1985a; Van Beek et al. 1984). It is probably responsible for most of the effects of V. africana seed consumption. See also *Chemical Index*, **Tabernaemontana** and **Tabernanthe** for more on pharmacology of this group of indole alkaloids.

V. africana root bark has yielded 3.7-10% alkaloids – *voacangine* [0.4%], voacimidine [0.8%], *voacamine* [1.4%], *voacamine* N-oxide [0.043%], vobtusine [papuanine; causes agitation followed by sedation in animals, hypotensive, cardiac depressant, causes convulsions in high doses], voacorine [CNS-depressant, hypertensive, cardiotonic], 3,6-oxido-*voacangine* [0.08%], *ibogaine* [0.02%], *coronaridine* [0.02%] and tabersonine [0.02%]; leaves yielded 0.3-2.03% alkaloids – *voacangine*, *voacamine*, vobtusine [0.0003%], voaphylline [conoflorine; 0.0265%], voaphylline OH-indolenine [0.0025%], voaphyllinediol [0.0003%], voafoline [0.0005%], isovoafoline [0.00005%], voafolidine [0.0001%], folicangine, 2-deoxy-18-oxovobtusine [0.001%], 18-oxovobtusine [0.0014%] and 2-deoxyvobtusine [0.0011%]; trunk/stem bark yielded 0.97-5% alkaloids – *voacangine* [0.14-0.17%], *voacangine* OH-indolenine [0.00625%], *voacangine* pseudoindoxyl, *voacamine* [0.04-0.6%], *voacamine* N-oxide, decarbomethoxy-*voacamine* [0.0025%], voacorine [0.093-0.38%], *vobasine* [0.04-0.7%], vobasinol [0.01%], vobtusine [0.01-0.12%], *voacristine* [0.1-0.25%], 20-OH-voacamidine, voacafrine [0.05%], voacafricine [0.01%], voacryptine, β-*yohimbine* [0.0025%], 3-epi-α-*yohimbine* [0.015%], pseudoyohimbine [0.00025%], *reserpine* [0.01%], *ibogaine* [0.01%], iboluteine [0.0025%], *ibogamine* [0.00125%], *iboxygaine* [0.0025%], *coronaridine* [0.00075%], perivine [0.01%] and perakine [0.00075%]; and seeds yielded 1.5-3.5% alkaloids – almost entirely tabersonine, as well as the ketone-derived alkaloids Δ14-vincanol [0.2%], O-methyl-16-epi-Δ14-vincanol [0.3%], and Δ14-vincamone. Leaves have also yielded 0.17% flavonoids. Leaves, bark and roots gave positive tests for saponins (Bisset 1985a; Ganzinger & Hesse 1976; Janot & Goutarel 1955; Pegnyemb et al. 1999; Richard et al. 1983; Thomas & Biemann 1968).

V. bracteata root bark has yielded 12.1% alkaloids – *voacangine*, *voacristine*, *voacamine* and 3 other bases; stem bark yielded 2.46% alkaloids – *voacangine* [0.094%], *voacamine* [0.22%], *voacamine* N-oxide, voacorine [0.038%], (-)-20-epi-voacorine [0.146%], *voacristine* [0.004%], (-)-19-epi-*voacristine* [0.058%], alkaloid G [0.007%] and alkaloid H [0.116%]; seeds yielded mostly tabersonine in unspecified amounts (Bisset 1985a).

V. grandifolia alkaloids reach a maximum in all parts in November, with the minimum yields in March [plant was 10-12 years old, cultivated in Calcutta]; maximum yields were 2.4% in root bark – including *voacangine* [0.14%], *voacamine* [0.02%] and vobtusine [0.44%]; 1.7% in trunk and branch barks – *voacangine* [0.035%], *voacamine* [0.0012-0.2%], vobtusine [0.006-0.02%] and 18-oxovobtusine [0.0015%]; 1.2% in leaves – vobtusine [0.03-0.65%], *voacamine* [0.0009%], 2-deoxyvobtusine [0.002%], 18-oxovobtusine [0.0002%] and amataine; and 1.2% from fruits – *voacangine*, vobtusine [0.01-0.52%], (-)-tabersonine [0.0015%], (+)-*akuammidine* [0.004%] and *voacamine* [traces] (Bisset 1985a; CSIRO 1990; Majumdar & Dinda 1974).

V. megacarpa bark yielded *voacamine* and vobtusine (Magno et al. 1965).

V. thouarsii root has yielded 1.2% alkaloids, mostly vobtusine [0.5%], the identity of the others not having been pursued; stem bark yielded 1.9-2.71% alkaloids – *voacangine* [0.15-0.28%; specifically not found in one analysis], *voacamine* [0.027%], vobtusine [0.019-0.1%; specifically not found in one analysis], (-)-dregamine [antifatigue agent, local anaesthetic, respiratory stimulant, convulsant], *ibogaine* [0.04%], iboluteine [0.0008%], (-)-*voacristine* [0.004%], (-)-voaluteine [0.0004%] and 18-decarbomethoxy-*voacamine* [0.0006%]; leaf yielded 1.08% alkaloids – vobtusine [main alkaloid], amataine, *ibogaine*, *voacangine*, *voacristine*, 18-oxovobtusine, (-)-18-oxoamataine, 3'-oxovobtusine [alkaloid A], 3'-oxovobtusine N-oxide [alkaloid B], 2-deoxy-3'-oxovobtusine [alkaloid D], 12-demethylvobtusine [alkaloid F] and alkaloids C, E & G; seeds contain tabersonine (Bisset 1985a; Ganzinger & Hesse 1976; Janot & Goutarel 1955; Rolland et al. 1973).

V. caudiflora and V. chalotiana also contain tabersonine as the predominant seed alkaloid (Bisset 1985a), and may have similar psychoactivity to V. africana seeds.

Voacanga africana is a shrub or tree up to 10(-25)m tall; trunk terete, 2-30(-40)cm diam.; bark pale grey-brown, smooth or shallowly fissured near base; branches lenticellate; branchlets glabrous, puberulous or pubescent, with more latex than in the bark. Leaves broadly ovate or subrhomboid, apex acute or bluntly subacuminate, base cuneate, up to 7-41.5 x 3-20cm, softly pubescent (sometimes only on midrib and secondary nerves) beneath, lateral nerves in c.10 pairs, raised beneath, tertiary venation reticulate, impressed. Inflorescence a 10-12-flowered terminal corymb; calyx green, usually shed with corolla, 5-lobed, lobes obtuse, +- 0.5cm long; calyx tube +- 0.5cm long, or longer when lobes erect; limb +- 3cm across; corolla lobes spreading, overlapping to the left, pure white, broadly deltoid, +- 1.8cm long or longer, contorted in bud; stamens 5, epipetalous, alternating with corolla lobes; anthers sessile, narrowly triangular, acuminate at sterile apex, sagittate at base, glabrous, introrse. Ovary mostly broadly ovoid; carpels free or connate at base, surrounded by a ring-shaped connate entire or lobed disc; disc adnate to abaxial sides of carpels; style 1, thickened at apex; clavuncula with thin ring at base, obovoid with 5 short lateral lobes, coherent with the connectives of the anthers; style and stigma shed with corolla; stigma short. Fruit of 2 separate mericarps of which often only one develops; mericarps single or in pairs, united only at base, fleshy when young, coriaceous and dehiscent when ripe, 3-8 x 3-8 x 2.5-7cm, obliquely subglobose, dark or pale brown, very pale green-spotted, with very large, conspicuous, buff lenticels, and with one deep groove to ½ the width on the hilar side, 2-valved, wall 5-15mm thick. Seeds many, dark brown, dull, obliquely ellipsoid, 7-10 x 3.5-5 x 3-4mm, 4-5 grooved laterally, rough, minutely tuberculate; aril orange; endosperm copious, starchy, creamy to white, ruminate, surrounded by spathulate embryo. Fl. Oct., fr. Aug.

Open woodland, bush or light forest, riverine forests, in savannas only in moist places or 'gallery forests', 0-1100m; widespread in tropical Africa and on islands in Gulf of Guinea, especially common near West African coast (Exell et al. ed. 1960-1993; Hutchinson & Dalziel 1954-1972; Leeuwenberg 1985; White 1962).

V. grandifolia occurs in Malesia, as well as Australia [Torres Strait and Cape York Peninsula] (Forster & Williams 1996).

WITHANIA

(Solanaceae)

Withania somnifera *(L.) Dunal* **(W. kansuensis** *Kuang et A.M. Lu***; Physalis somnifera** *L.***)** – ashwagandha, asgandh, jangida, kuthmithi, asundha, asana, Indian ginseng, winter cherry

Mentioned frequently in the Atharva Veda of the Hindus, 'ashwagandha' ['horse-root'] is considered second in importance only to 'soma' [see **Amanita**], and is much-used in Ayurvedic medicine. The plant is considered a magical aphrodisiac, elixir of life, remedy and charm. Roots taking on a human shape are said to be more powerful, an anthropocentric myth similar to those surrounding ginseng and mandrake [see **Panax** and **Mandragora**, respectively]. The dried root, called 'kuthmithi', is sold in Indian markets, and is generally used as a nerve tonic, aphrodisiac, rejuvenative and asthma treatment. It is infused as a safe sedative tonic by both adults and children with no observed toxicity. Roots and leaves are often interchanged, as they share similar properties; they are also both used as a hypnotic in treating alcoholics. The fruits, due to their high saponin content, are used to make soap; seeds are said to be poisonous (Bone 1996; Chopra et al. 1958, 1965; Emboden 1979a; Grandhi et al. 1994; Kirtikar & Basu 1980; Nadkarni 1976; Rätsch 1990, 1992). In Africa, a preparation of the whole plant is taken internally to tone the uterus after a miscarriage, and is macerated in oils and applied topically on boils and swellings. The herb is also known in Africa as a hypnotic, aphrodisiac and abortifacient (Watt 1967; Watt & Breyer-Brandwijk 1962).

The whole plant is a **Panax**-like tonic and adaptogen, also acting as an immune stimulant, hypnotic, tranquilliser, sedative, narcotic, analgesic, hypotensive, respiratory stimulant, vasomotor stimulant, appetite stimulant, astringent, brachycardiac, antirheumatic, antiinflammatory, antitumour [in high doses], antiparasitic and anti-stress agent (Bone 1996; Chopra et al. 1958, 1965; Davis & Kuttan 2000; Grandhi et al. 1994; Kirtikar & Basu 1980; Nadkarni 1976; Rastogi & Mehrotra ed. 1990-1993). An extract also inhibited *morphine* tolerance and dependence, and reduced withdrawal symptoms in mice (Kulkarni & Ninan 1997).

W. somnifera root has yielded alkaloids, such as somniferine, somnifernine, withasomnine, somnine, withanine, withananine, withananinine, *nicotine*, hygrine, anahygrine, cuscohygrine, tropine, pseudotropine, 3-α-tigloyloxytropane, dl-isopellieterine, anaferine and *choline*; c.2.84% steroidal lactones called withanolides [many with antitumour properties] and withaferins [withaferin A shows cytotoxic and antitumour properties]; sitoindosides; and iron. Leaves and fruits also contain withanolides and withaferins (Abraham et al. 1975; Bone 1996; Chopra et al. 1958, 1965; Farnsworth & Cordell 1976; Grandhi et al. 1994; Rastogi & Mehrotra ed. 1990-1993; Schwarting et al. 1963; Yu et al. 1974); leaves were also shown to contain calystegines B2 and C1 (Bekkouche et al. 2001). Shoots and flowers yielded *scopoletin* and aesculetin [0.00025% combined, w/w] (Kala 1958). The withanolides coagulin and withasomidienone have also been isolated from members of the genus (Rahman et al. 1993).

Withania somnifera is an erect, sprawling shrub 30-150cm tall, with nearly all parts +- stellately matted with hairs; branches terete. Leaves 5-10 x 2.5-5cm, ovate, entire, +- minutely stellately pubescent, sub-acute, base acute; main nerves in c.6 pairs, stout, conspicuous; petioles 6-13mm long, stellately tomentose. Flowers greenish or lurid-yellow, 8-13mm long, hermaphrodite, usually c.5 together in sessile or subsessile axillary umbellate cymes; pedicels 0-4mm long; calyx campanulate, 5mm long in flower, stellately tomentose, 5-6-toothed, teeth linear, acute, 2.5mm long, from a deltoid base; corolla campanulate, 8mm long, divided more than ½ way down, lobes 3-6, lanceolate, short, acute, pubescent outside; stamens 5, attached near base of corolla; filaments 3mm long, slender, glabrous; an-

thers broadly elliptic, almost orbicular, 1.25mm long, dehiscing longitudinally. Ovary glabrous, 2-celled; ovules numerous; style glabrous, linear; stigma shortly 2-fid. Berry 6-8mm diam., 13-20mm long, bright red or yellow when ripe, enclosed in translucent papery calyx, globose, slightly 5-angled, pointed with the connivent calyx-teeth, scurfy-pubescent outside; seeds 2.5mm diam., yellow, somewhat silvery and hairy.

India in drier areas, in open places and waste areas, up to 1680m in the Himalayas; also in south and tropical Africa (Chopra et al. 1965; Kirtikar & Basu 1980), as well as Balearic Islands, Spain, Greece, Crete, Sardinia and Sicily (Tutin et al. ed. 1964-1980).

Cold-hardy [though only moderately frost-tolerant], laying dormant in winter (pers. obs.).

ZANTHOXYLUM [Xanthoxylum]

(Rutaceae)

Zanthoxylum arborescens *Rose* **(Z. goldmanii** *Rose ex P. Wilson***; Z. peninsulare** *Brandegee***; Fagara arborescens** *(Rose) Engl.***; F. goldmanii** *(Rose ex P. Wilson) Engl.***)** – prickly ash

Zanthoxylum clava-herculis *L.* **(Z. americanum** *Mill.***; Z. carolinianum** *Lam.***; Z. catesbianum** *Raf.***; Z. clavatum** *St.-Lager***; Z. fraxineum** *Willd.***; Fagara caroliniana** *(Lam.) Engl.***; F. clava-herculis** *(L.) Small***; Thylax fraxineum** *(Willd.) Raf.***)** – Hercules' club prickly ash, southern prickly ash

Zanthoxylum hamiltonianum *Wall. ex Hook. f.* **(Z. nitidum** *(Roxb.) DC.***)** – tezmoi, tezmuri, changre, parpar timur, lian mian zhen

Zanthoxylum martinicense *(Lam.) DC.* **(Z. album** *Vahl***; Z. amoyense** *Tul.***; Z. juglandifolium** *Willd.***; Z. lanceolatum** *Poir.***; Fagara amoyensis** *(Tul.) Engl.***; F. martinicensis** *Lam.***)** – bwa pine

Zanthoxylum microcarpum *Griseb.* **(Z. rhoifolium** *Lam.***; F. microcarpa** *(Griseb.) Krug et Urb.***)** – rabo lagarto

Zanthoxylum procerum *Donn.-Sm.* **(Z. acuminatum** *(Sw.) Sw.***; Z. juniperinum** *Poepp.***; Fagara procera** *(Donn.-Sm.) Engl.***)** – toothache tree

Zanthoxylum schinifolium *Sieb. et Zucc. (***Z. mantschuricum** *Benn.***; Z. pteropodum** *Hayata***; Fagara pteropoda** *(Hayata) Y.C. Liu***; F. schinifolia** *(Sieb. et Zucc.) Engl.***)**

Several Zanthoxylum spp. are used in a variety of medicinal applications around the world. Z. alatum [Z. planispinum], 'wingleaf prickly ash', is used for its seeds to treat stomach ache in China. Z. piperitum fruit ['hua jiao'] is considered stimulant, carminative, diuretic and anthelmintic in China [dose – 3-5g], and is used as a cooking spice ['Szechuan pepper']. Dried root of Z. hamiltonianum ['lian mian zhen'] is used in TCM as an analgesic and circulatory stimulant. Z. hamiltonianum fruit is considered a stimulant in India, where along with Z. alatum its roots and bark are used to kill fish. In Nepal, Z. oxyphyllum fruit ['sil timbur'] might be an ingredient of an incense used to guard against witches. 'Senegal prickly ash', Z. senegalense, is used in tropical Africa – seeds treat rheumatism, and the bark is a sudorific. The Cherokee use Z. clava-herculis to bathe swollen joints, and it is used in southern US as a bark decoction to treat toothache and rheumatism, whilst the berries are considered a tonic stimulant (Chin & Keng 1990; Chopra et al. 1965; Hamel & Chiltoskey 1975; Huang 1993; Keys 1976; Müller-Ebeling et al. 2002; Usher 1974).

In Mexico, Z. microcarpum bark is used as a stimulant and analgesic (Jiu 1966). Z. martinicense, considered narcotic, is an ingredient of some Haitian zombi potions [see *Methods of Ingestion*]. A leaf and bark preparation is used in Cuba as a tonic, and to treat syphilis, rheumatism and alcoholism; the bark is chewed for toothache. The astringent root juice is used in Jamaica for gastrointestinal upsets, and the bark is considered to be antispasmodic (Davis 1988a). Also, an Amazonian Zanthoxylum sp. [Z. cf. tachuelo – 'mina-ko-ro'] is used by the Kofan, who apply a bark decoction as an external analgesic. It may also sometimes be drunk for unclear purposes [unclear to us, that is – presumably those using it in such a fashion would know what effects to expect] – this latter use apparently was given to them by a shaman who had communicated with 'demons' (Schultes & Raffauf 1990).

Z. alatum bark has yielded berberine (Chopra et al. 1965).

Z. arborescens is of more interest to us, as its leaves have yielded 0.09% *DMT*, as well as 0.002% *N-methyltryptamine*, 0.04% 1-methyl-3-(2'-phenylethyl)-1H,3H-quinazoline-2,4-dione, 0.01% 1-methyl-3-[2'-(4"-methoxyphenyl)ethyl]-1H,3H-quinazoline-2,4-dione, 0.01% *skimmianine*, and three new alkaloids – 0.05% 8-(2-isopentenyloxy)-4,7-dimethoxy-furo[2,3b]quinoline, 0.03% 8-OH-4,7-dimethoxyfuranoquinoline and 0.006% (+)-(2S,5S)-2,5-dibenzyl-1,4-dimethylpiperazine. Bark yielded 0.15% (+)-tembetarine, 0.007% of the first quinazoline-compound listed above, and 0.007% of the first new alkaloid. Wood yielded 0.02% *hordenine*, 0.01% (+)-tembetarine and 0.03% (-)-4-[2-(dimethylamino)ethyl]-phenyl-β-D-glucopyranoside (Grina et al. 1982).

Z. brachyacanthum from Ravenshoe and Yarraman, Queensland [Australia], harvested in August and October, gave strong positive tests for alkaloids in both leaf and bark (Webb 1949).

Z. clava-herculis root bark has yielded laurifoline, nitidine, chelerythrine, magnoflorine [see **Magnolia**], tembetarine, candicine [4-OH-N,N,N-trimethyl-*phenethylamine*], herclavine, xanthyletin and xanthoxyletin; stem bark yielded the same compounds in lesser concentration, except chelerythrine was absent (Fish et al. 1975; Lundstrom 1989). The plant has been shown to inhibit human plasma AChE (Orgell 1963b).

Z. conspersipunctatum has yielded the *phenethylamine*-conjugate tembamide (Lundstrom 1989).

Z. hamiltonianum has yielded nitidine, oxynitidine and vitexin (Huang 1993).

Z. oxyphyllum stem bark yielded the indole alkaloid rhetsinine [hydroxyevodiamine] (Chatterjee & Mukherjee 1964), which is also found in **Evodia** rutaecarpa.

Z. piperitum fruits have yielded 2-4% essential oil, containing limonene, phellandrene, geraniol, and sanshool; xanthoxylin is also found in the fruits and berberine in the roots (Keys 1976).

Z. procerum leaves have yielded mainly culantraramine and culantraraminol, as well as lesser amounts of alloculantraraminol, 5-epiculantraraminol, *DMT* and *hordenine* (Schroeder 1986); also found in the plant is 3-(3,4,5-trimethoxyphenyl)-2-propenal (Buckingham et al. ed. 1994).

Z. schinifolium stems yielded the coumarin lacinartin, which inhibited mouse brain MAO [MAO-A more than MAO-B] (Jo et al. 2002).

Z. thomense stem bark from Congo yielded 0.15% crude alkaloids, including 0.06% zanthomamide [N-methyl,N-cinnamyl-(3',4'-methylenedioxy)-*phenethylamine*], 0.03% angoline, 0.075% decarine and 0.016% norchelerythrine (Simeray et al. 1985).

Z. torvum bark from Cairns, Queensland [harv. Sep.] tested strongly positive for alkaloids.

Z. veneficum leaf and bark from Malanda, Queensland [harv. Aug.] tested strongly positive for alkaloids (Webb 1949).

Zanthoxylum arborescens is a shrub or tree with aromatic bark, to 6m tall, with unarmed branches, or armed with scattered, slightly curved, stout spines, often with heavier conical spines on trunk; twigs, petioles, rachis of leaves, and branches of inflorescence hispidulous. Leaves alternate, unifoliate, odd-pinnate, 10-20cm long, usually with stipular spines; leaflets (3-)5(-7), oblong-elliptic to obovate, 1.5-4cm wide, 3-7.5cm long, cuneate at base, acute to obtusely short-acuminate at apex, entire to crenulate, tomentulose beneath, hispidulous to glabrate above, with pellucid glands; petioles and rachis often winged. Inflorescence paniculate; calyx hypogynous or wanting; sepals (4-)5, triangular-ovate, 1.5-2mm long; petals 3-10, 2.5-3mm long, greenish-yellow; stamens 5, hypogynous, reduced or lacking in pistillate flowers; pistils 1-5; ovaries 1-celled, each 2-ovuled; styles somewhat united near summit. Fruits follicular, follicles ellipsoid to subglobose, subsessile, 4-6mm long; seeds ellipsoid, 3.5-4.5mm long, black and shiny. Fl. Sep.-Oct.

Rocky canyons, dry arroyos and valley floors; Lower Sonoran and Subtropical zones, s. Baja California and Sinaloa (Shreve & Wiggins 1964).

ZIERIA

(Rutaceae)

Zieria arborescens *Sims* **(Z. smithii var. macrophylla** *(Bonpl.) Benth.***)** – stinkwood, tree Zieria

Zieria cytisoides *Sm.*

Zieria laevigata *Sm.* – angular Zieria, native candytuft, twiggy midge bush

Zieria laevigata var. fraseri *(Hook.) Domin* **(Z. fraseri ssp. 'a'** *Armstrong***)**

Zieria smithii *Andr.* – sandfly Zieria, sandfly bush, native sassafras bush

Zieria spp.

This group of Australian shrubs is of modern interest due to the phenylpropene content of some of their essential oils [which, unfortunately, can be highly variable]. Although they do not seem to have any uses by humans, Z. smithii and Z. arborescens are known to cause a stock intoxication called 'panting disease', which often results in death weeks after consumption. However, the plants are not very palatable, and are rarely eaten by choice. Z. laxiflora is also suspected of causing intoxications in stock animals, though there is little evidence to support this. The toxic principles are undetermined (Hurst 1942).

Z. sp. aff. arborescens [Z. sp. nov. 'F'] yielded 0.4-2% essential oil, consisting of 7.6-23.4% *myristicin*, 0-6.4% *elemicin*, 1.7-5.1% *methyleugenol* and 0-1.2% *safrole*.

Z. arborescens sens. strict. [Z. arborescens ssp. 'a'] yielded 0.2-3.2% essential oil, containing 0-15.1% *safrole* and 0-7.2% *methyleugenol*.

Z. arborescens ssp. 'b' [ringed-stem form] yielded c.2% essential oil, containing 5.7% *safrole* and 2.5% *methyleugenol*.

Z. arborescens ssp. 'c' [broad-leaved form] yielded 0.6-3% essential oil, containing 2.4-94.1% *safrole*, 0-9.3% *methyleugenol*, 0-52.8% *elemicin* and 1-2.9% 1,3,5-trimethoxybenzene.

Z. arborescens ssp. 'e' [hairy-stem form] yielded 1.7-5% essential oil,

containing 12.7-26.3% *safrole* and 12.9-47.5% *elemicin*.

Z. cytisoides sens. strict. [Z. cytisoides ssp. 'a'] yielded 0.2-0.6% essential oil, containing 0-22% *safrole* and 0-12.3% *methyleugenol*.

Z. cytisoides ssp. 'b' [coastal form] yielded 0.2-0.6% essential oil, containing 1.2-11.3% *safrole* and 0-53.3% *methyleugenol*.

Z. laevigata sens. strict. [Z. laevigata ssp. 'a'] yielded 0.1-0.35% essential oil, containing 0-4.7% *myristicin* and 1.3% *methyleugenol*.

Z. laevigata var. fraseri [Z. fraseri ssp. 'a'] yielded 0.1-1.2% essential oil, containing 15.9-33.8% *methyleugenol* and 2.4-15.4% *safrole* (Flynn & Southwell 1987). Aerial parts yielded 0.16-0.49% hydrocyanic acid [HCN]; the plant does not contain this compound, but it contains a glucoside, zierin, which reacts with an enzyme when the plant is crushed to form HCN (Hurst 1942).

Z. smithii sens. strict. [Z. smithii ssp. 'a'] yielded 0.5-8% essential oil, containing 0-81.2% *safrole*, 0-93.6% *methyleugenol*, 0-83.6% *elemicin* and 0-1.3% *eugenol*.

Z. sp. aff. smithii [Z. sp. nov. 'J'] yielded 0.6-4.8% essential oil, containing 90-95.5% *safrole*.

Z. smithii ssp. 'b' [tomentose form] yielded 0.8-1.5% essential oil, containing 1-19% *safrole*.

Z. smithii ssp. 'c' [glabrous form] yielded 0.7-4.8% essential oil, containing 4.7-32.2% *safrole*, 57.9-61.4% *elemicin* and 0-6.3% *methyleugenol*.

Z. smithii 'd' form [Z. sp. nov. 'E' ssp. 'a'] [robust mountain form] yielded 0.4-2.8% essential oil, containing 5.5% *safrole*, 84.8% *elemicin* and 1.2-4.1% 1,3,5-trimethoxybenzene.

Z. smithii 'e' form [Z. sp. nov. 'E' ssp. 'b'] [glabrous mountain form] yielded 0.9-1.9% essential oil, containing 52.5-59.1% *safrole*.

Z. smithii 'f' form [Z. sp. nov. 'E' ssp. 'c'] [prostrate mountain form] yielded c.0.5% essential oil, containing 41.4% *safrole* and 27.7% *eugenol* (Flynn & Southwell 1987). Z. smithii leaves have yielded 0.046-0.057% HCN, which was also observed in the stems (Hurst 1942). Leaf, stem, and root from Brisbane, Queensland [harv. Mar.] tested strongly positive for alkaloids in some assays (Webb 1949).

Other species also yield minor quantities of the above phenylpropenes, and many others do not. Many of these oils are high in compounds such as naphthalene, chrysanthenone, cis-chrysanthenyl acetate, zierone, limonene and α-*pinene*. Z. arborescens, Z. furfuracea, Z. laevigata and Z. smithii have all been reported to be cyanogenic (Flynn & Southwell 1987), and as such it would seem unwise to ingest these plants directly.

Zieria arborescens is a tall shrub or small tree. Leaves and stems pubescent, or if glabrous, then with prominent tubercles, dotted with translucent oil glands; leaves opposite, trifoliate; leaflets elliptic to narrow-elliptic or lanceolate, 5-10cm long, glabrous or hairy beneath. Flowers regular, bisexual, in axillary cymes, rarely solitary; calyx 4-5-lobed, lobes shorter than petals; petals 4, spreading, free, white, 3-7mm long; stamens 4; anthers without a terminal point. Ovary superior, deeply lobed, surrounded by a perigynous disc, 4-5-locular; 1-2 ovules per loculus; style usually simple; carpels 4, nearly distinct. Fruit a dehiscent schizocarp capsule; 1 seed per carpel. Fl. spring-summer.

Widespread, in moister forests, mountain slopes, gullies; Australia [Victoria, New South Wales, Queensland] (Carolin & Tindale 1994; Costermans 1992).

ZIZIPHUS [Zizyphus]

(Rhamnaceae)

Ziziphus jujuba *Mill.* **(Z. sativa** *Gaertn.***; Z. vulgaris** *Lam.***; Z. zyzyphus** *(L.) Karsten***; Rhamnus ziziphus** *L.***)** – Chinese date, wild Chinese jujube, suan zao ren, shan dzao, da zao

Ziziphus mauritiana *Lam.* **(Z. jujuba** *(L.) Gaertn.***; Z. jujuba** *(L.) Lam.***; Z. mairei** *(H. Lév.) Browicz et Lauener***; Paliurus mairei** *H. Lév.***; Rhamnus jujuba** *L.***)** – Indian jujube, Indian cherry, Indian plum, ber, bush cherry, nabagaya

Ziziphus napeca *Willd.* – kakoli, kankla, kattivatigai, teumani-chettu

Ziziphus spina-christi *(L.) Desf.* **(Rhamnus spina-christi** *L.***)** – Christ's thorn, jujubier de Palestine, bauyer, batomono ['jujube of the river'], dabi furu, kurna, surgô tomono, seder

Ziziphus spinosa *Hu* – Chinese date, wild jujube, sour jujube, suan zao ren, suan zao

Chinese dates [Z. jujuba and Z. spinosa] are prized in TCM as a 'kingly tonic'. The dried seed is decocted in doses of 5-18g to treat insomnia, neuraesthenia, irritation, heart palpitations, hypertension, profuse sweating, chronic thirst and malnutrition. It is considered to have an affinity for the heart, liver, spleen and gallbladder. The fruit is also used, in a dose of 3-5 fruits, as a nutrient tonic and sedative for insomnia. The drug is considered incompatible with plants of the Menispermaceae. Chinese dates may stimulate the immune system, nourish the muscles and enrich bone marrow, whilst acting as a tranquillising hypnotic, sedative, analgesic and anticonvulsant. They may be used regularly with no harmful side-effects. In India, Ayurvedists use the fruit of Z. mauritiana as an aphrodisiac, tonic, laxative blood purifier that may also be used to treat burning sensations and vomiting. The bitter, cooling leaves are also used for diarrhoea, obesity and fever; the bark is used for boils and dysentery; and the root for delirium, headache, fever and to promote hair growth; all parts are used to treat biliousness (Bremness 1994; Huang 1993; Keys 1976; Kirtikar & Basu 1980; Nadkarni 1976; Reid 1995). In addition, the bark has emetic properties and is sometimes considered 'dangerous' (Perry & Metzger 1980).

In Katanga, Africa, the root of Z. jujuba is used as an epilepsy remedy (Watt 1967); in China it has also been used as an antagonist to the actions of Aconitum spp. and 'gentian' [Gentiana spp.] [see *Endnotes*]. In Korea, the seeds have been used as a hypnotic narcotic (Perry & Metzger 1980). The wood is of a fine quality, and is used to manufacture a wide range of things. An excellent honey may also be made from the flower nectar (Outlaw et al. 2002).

In Ethiopia, Z. mauritiana bark is used as a fish poison. In Senegal, the Nyominka observe a 'tabu' on the fruits, which are reserved for the use of Muslim priests. In Somalia, Muslims believe that if they die during the 14 days the fruit is considered to remain in the stomach, they will ascend directly to Paradise. In Botswana, it is believed that drought will come if someone cuts down a Z. mucronata tree after the first summer rain. It is believed to ward off lightning, and the Tenda consider it to be a charm for hunting antelope. The fruit pulp has analgesic activity, and has been used to relieve earache and toothache. Although often said to be toxic, the bitter, acrid pulp is still sometimes cooked into a kind of porridge for food; when dried and fermented, it is made into cakes called 'lotus bread'. The seeds are sometimes roasted to make a coffee substitute [see **Coffea**] (Burkill 1985-1997). The plant is used in Angola to poison fish. In Malawi, Z. abyssinica fruit is used to make alcoholic beverages [see *Methods of Ingestion*] (De Smet 1998). In India, Z. napica root is used as an aphrodisiac, nutrient and antipyretic (Nadkarni 1976). Z. joazeiro is considered a protective tree by the Kariri-Shoko, 'jurema-drinkers' [see **Mimosa**] of n.e. Brazil (Da Mota 1997).

Z. spina-christi is believed to have been the plant from which Christ's crown of thorns was fashioned, although today there are varieties of the plant which have been selectively bred to bear no spines. Others believe the plant used was the related 'Jerusalem thorn', Paliurus spina-christi. The fruit of Z. spina-christi is considered delicious to eat. Z. spina-christi is now thought to have been the 'lotus' of the Lotophagi ['lotus-eaters'] referred to in Homer's 'The Odyssey', the flowers and fruit of which overtook Odysseus' crew with narcosis when they visited the land of the Lotophagi [probably in modern Libya]. This plant was previously thought to have been the similar Z. lotus (Burkill 1985-1997), though others believe it to have probably been a **Nelumbo** or **Nymphaea** (Jones 2001). This latter option may be more likely, as the fruits of Z. spina-christi are a renowned food and do not have a reputation for psychotropic activity. However, perhaps it is the seeds of this species which are psychoactive. These diverse plants known as 'lotus' should not be confused with the leguminous herbs Lotus spp. [see *Endnotes*].

Z. jujuba and Z. spinosa fruits have yielded 12 phenanthrene isoquinoline-type alkaloids, including asimilobine, N-methylasimilobine, *nuciferine*, N-nornuciferine, oxonuciferine, zizyphusine, stepharine, norisocorydine, caaverine and (+)-coclauline, as well as vitamins, sugars and organic acids. Seeds have yielded 14 peptide alkaloids named samjoinines, as well as glucosides [jujubosides A & B; convert to jujubogenin on hydrolysis], betulin and betulic acid. The stems also contain peptide alkaloids, but these apparently do not share the sedative action of the seeds and fruit (Buckingham et al. ed. 1994; Huang 1993; Rastogi & Mehrotra ed. 1990-1993). Seeds also contain the flavonoid glycoside spinosin, which has sedative and hypnotic activity (Outlaw et al. 2002). In mice, the seeds showed sedative activity only with higher doses, and had anxiolytic effects at lower doses (Penga et al. 2000).

Z. mauritiana root bark has yielded peptide alkaloids including mauritines A-H, mauritine J, frangufoline, amphibine B and amphibines D-F (Jossang et al. 1996); flavonoids, glycosides, saponins and an essential oil were also detected (Dahiru et al. 2006).

Z. spina-christi bark [harv. Jan., Nigeria] yielded peptide alkaloids – mostly mauritine-A [0.025%], with smaller amounts of mauritine C, amphibine A, amphibine E and amphibine F (Tschesche et al. 1974).

Ziziphus jujuba is a small, subdeciduous tree with a dense, spreading crown, commonly 60cm girth and 6m tall; bark blackish to grey or brown, rough, regularly and deeply furrowed, the furrows c.1.2cm apart; blaze 9-13mm, short fibre, pink with or without paler streaks, the juice turning purplish-black on the blade of a knife; branches usually armed with spines, mostly in pairs, one straight, the other curved. Young shoots +- densely pubescent; leaves alternate, subdistichous, 3-6.3 x 2.5-5cm, oblong or ovate, usually minutely serrulate or apex distinctly toothed, obtuse, base oblique and 3-nerved, nerves depressed on the glabrous shining upper surface, densely clothed beneath with white or buff tomentum; petiole 2.5-10mm long. Flowers 3.8-5mm diam., greenish, in dense axillary tomentose cymes or fascicles 1.2-1.9cm long; calyx with broadly obconic tube and 5 triangular acute lobes keeled within, lobes valvate; petals 5 or rarely 0, cucullate, deflexed; stamens 5, opposite to and enclosed in the petals and usually longer than them. Disc 5-10 lobed, flat or pitted,

margin free; ovary sunk in or adnate at base to the disc, 2-4 celled; styles 2-3(-4), free or connate; stigmas small, papillose. Fruit a globose or oblong drupe, 1.2-2.5cm diam., first yellow then orange and finally reddish-brown, containing a single stone surrounded by fleshy pulp.

Indigenous and naturalised throughout India, Burma, Ceylon, outer Himalayas to 1370m, China, Australia, Afghanistan, Africa (Kirtikar & Basu 1980).

To obtain seed, the stones must be cracked open; keep moist and warm, should germinate in a few weeks. Raising strong plants past this point has proven difficult in Australia; propagating from transplanted root suckers may be a more viable option. Potential weed due to roots sending up new shoots. Frost tolerant to c. -10°C or more when dormant; heat tolerant. Better adapted to arid regions, but will grow in a wide range of climates. Grows in a wide variety of soils, but fruits poorly in humid or very moist conditions. The 'Indian jujube' [Z. mauritiana] is more cold-sensitive and does better in such humidity. Requires long hot summers and clear skies for fruit to ripen fully. Sometimes fruits split and spoil before maturity. Fruits may be harvested and eaten when mature [when the skin is bright green and shiny] for a crisp, apple-like taste; or, they may be left to ripen further on the tree, turning brown and finally a rich bronze-red, becoming wrinkled and partially dried. As birds may eat them before you do, it is sometimes considered best to harvest when they have developed a few brown patches, then allowed to ripen off the tree. Fruits may be eaten as they are, or slashed and boiled with sugar/honey syrup several times before drying, resulting in a fruit that will store for longer periods. Care should be taken with the two sharp, pointed ends of the seed kernel (Glowinski 1997; Outlaw et al. 2002).

These sources of 'dates' should not be confused with the source of common dates, the unrelated Phoenix dactylifera (Palmaceae). Z. jujuba *Mill.* should not be confused with Z. jujuba *(L.) Gaertn.* or Z. jujuba *(L.) Lam.*, which are synonymous with Z. mauritiana (Outlaw et al. 2002).

ZORNIA

(Leguminosae/Fabaceae)

Zornia diphylla *(L.) Pers.* **(Z. conjugata** *(Willd.) Sm.***; Z. reticulata** *Sm.***; Z. surinamensis** *Miq.***; Z. zeylonensis** *Pers.***; Hedysarum conjugatum** *Willd.***; H. diphyllum** *L.***)** – tandi-jhapni, nelammari, poor man's soap

Zornia gibbosa *Spanoghe* **(Z. angustifolia** *Sm.***; Z. cantoniensis** *Mohlenbr.***; Z. graminea** *Span.***)**

Zornia latifolia *DC.* **(Z. diphylla ssp. latifolia** *(DC.) Malme***; Z. diphylla var. latifolia** *(DC.) Benth.***; Z. ovata** *Vogel***; Z. sericea** *Moric.***)** – maconha brava

The leaves of Z. latifolia, as 'maconha brava' ['wild marijuana' – see **Cannabis**], are smoked in Brazil as a "hallucinogen". The plant is used to treat dysentery in San Salvador (Schultes & Hofmann 1980, 1992). Z. diphylla also treats dysentery, and acts as a febrifuge and diuretic. In southern India, the roots are given to children as a soporific. In Australia, horses feeding on it have suffered from impaired vision and mobility, suggesting psychotropic effects. This and other Zornia spp. are valued as good forage crops in parts of S. America and Africa (Allen & Allen 1981; Nadkarni 1976). In Papua New Guinea, Z. gibbosa has been used in sorcery (Schultes & Hofmann 1980).

Z. diphylla aerial parts have yielded 2H-1-benzopyran-2-one (International... 1994) and saponins (Allen & Allen 1981). The chemical compositions of Z. latifolia and Z. gibbosa are still unknown.

Zornia diphylla is a diffuse or erect herb, glabrous or pubescent-villose; root annual or persistent, forming thick, woody rhizomes; stems annual, short, much-branched, branches ascending or erect, c.60-90cm, terete or compressed. Leaves palmately 2-4-foliolate, stipellate; leaflets 2, ovate-lanceolate-linear; stipules ovate-lanceolate, acute, striate, affixed-peltate near base, below insertion in auricle short, obtuse or acute elongate, caducous. Flowers in terminal spikes, +- elongate, remote, sessile, yellow; bracts or bracteoles resembling stipules, flowers tightly appressed and almost entirely included; calyx hyaline or paleaceus, membranaceous, tubulose-campanulate, bilabiate, upper labia emarginate, lower labia 3-fid, lateral lobes short; corolla very short, labium ciliate, of equal length, lateral lobes very short, petals clawed, standard rotundate, bracts short or long, wing keel overtopping; stamens 10, in tube completely connate; anthers alternately oblong-linear, and ovate. Ovary subsessile, many-ovuled; style filiform; stigma small, subcapitate. Legume linear, compressed, 3-6-articulate, vexillary sutures straight, keel sinuate, joints compressed, immarginate, pubescent or glabrate, surface reticulate-venose, prickles arising from veins frequent, rare or absent, glabrous or apex glochidiate or on all sides reflexed-hairy.

South America (Fridericus & De Martius ed. 1965-1975), also widespread elsewhere as a forage crop (Allen & Allen 1981).

ZYGOPHYLLUM

(Zygophyllaceae)

Zygophyllum fabago *L.* – Syrian bean caper

In Italy, flower buds of this plant are pickled in vinegar and eaten in the same manner as 'capers' [Capparis spinosa (Capparaceae)]. The plant is also used there and in the Middle East as an anthelmintic (Festi & Samorini 1997). The related Z. album from n. Africa and the Canary Islands is used as a perfume, derived from a decoction of the flowers (Usher 1974). Also in Africa, Z. foetidum [when eaten in excess] is considered toxic to animals in early winter mornings, when grown in the shade, possibly due to highest alkaloid concentrations at this time [see **Phalaris**]. Z. herbaceum, Z. microcarpum, Z. microphyllum, Z. sessilifolium and Z. spinosum are also considered toxic to sheep. Z. morgsana powdered seed is used in the Cape area to treat convulsions, paralysis and stroke; it is also considered toxic, and is used with caution (Watt & Breyer-Brandwijk 1962).

Z. apiculatum leaf from Queensland [Australia], harvested February, tested strongly positive for alkaloids; assays of the whole plant harvested in June gave weaker results (Webb 1949). In later work, leaf [from Australia; harv. April] tested positive for alkaloids in preliminary screenings, but follow-ups found none (Fong et al. 1972).

Z. atriplicoides from Armenia contains unidentified alkaloids (Zolotnitskaya 1954).

Z. fabago contains β-carboline alkaloids. Roots have yielded 0.058% total alkaloids, consisting of *harmine* [0.007%], *harman* [0.014%] and *harmol* [seems to be major alkaloid], as well as 2 unidentified alkaloids; aerial parts have yielded 0.002% *harmine*, 0.008% *harman* and *harmol* (Borkowski 1960; Festi & Samorini 1997; Lutomski & Nowicka 1969; Lutomski et al. 1968a); stems alone yielded 0.00045% alkaloids calculated as *harman* [Table 1 in this paper actually lists 0.000045%, yet the former value is given in the summary of findings] (Lutomski & Malek 1975b). The plant has also yielded 3-β-OH-2-β,21-β-oleananolide (Buckingham et al. ed. 1994). The leaves have a very hot flavour, which has been compared to mustard [see **Brassica**] and capers; this strong taste may discourage use of the aerial parts in quantities sufficient for MAO-inhibition (theobromus pers. comm.).

Zygophyllum fabago is a much-branched perennial herb or subshrub, glabrous and bushy; stems terete, thick, smooth, branching from the base. Leaves opposite, 2-foliate, stipitate; leaflets elliptic-oval, oblique at base, rounded at apex, succulent, 10-35mm long. Flowers solitary, axillary; sepals 5, nearly distinct, 5-10mm long, margins whitish; petals 5, yellow or orange-yellow, 5-10mm long, clawed; stamens 8-10, exserted. Ovary sessile, 4- or 5-carpellate. Fruit angular, oblong, 1-4cm long; seed solitary in each cell. Fl. Jun.-Aug.

In waste ground, 1070-1520m; originally from Asia Minor, occurring also in s.e. Europe and w. Mediterranean region, also introduced to western US including s. New Mexico (Martin & Hutchins 1980).

APPENDIX A: ENDNOTES

This appendix is a collection of various snippets of information that could not be fully included in the main text due to space and time restrictions, or due to weak or tentative evidence for their activity. Here, in a loosely organised format, are compiled some interesting facts and preliminary observations, as well as pointers for further research.

MISCELLANEOUS SMOKING HERBS, TOBACCO, BETEL, TEA and COFFEE SUBSTITUTES

There are a group of diverse herbs used as substitutes for tobacco or pituri [see **Nicotiana**, **Duboisia**] by indigenous Australians. Many of these plants are known to have mild narcotic, stimulating, or otherwise psychoactive properties when chewed or smoked. Those not discussed more fully in the main body of the book are mentioned here.

Adriana glabrata (Euphorbiaceae) ['bitterbush'] dried leaves were sometimes smoked as a tobacco substitute by some tribes near Gladstone, Queensland. There appear to be two varieties of this species, which may explain why it is considered a useful forage plant in some areas, and a suspected stock intoxicant in others (Cribb & Cribb 1981; Low 1990).

An Amorphophallus sp., probably either A. variabilis [Brachyspatha variabilis] or A. glabra [many sources list this as 'galbra', which I suspect is a perpetually-repeated spelling error] (Araceae) ['stinking Arum'] has been smoked in the Daly River area, Northern Territory. It is dangerously narcotic with a chloroform-like effect – it is said that "a short smoke makes one sleepy; if he smokes for too long he will not awaken" (Cribb & Cribb 1981; Plowman 1969).

Callicarpa longifolia (Verbenaceae) ['chukin'] has not been used as a narcotic by indigenous Australians, though in the early 1900's, Japanese immigrants living near the Johnstone River, Queensland, chewed the bark with betel nut [see **Areca**] and lime, as a substitute for betel leaves [see **Piper 1**]. The plant has also been used as a fish poison (Cribb & Cribb 1981).

Centipeda cunninghammii ['common sneezeweed'], C. minima ['spreading sneezeweed'] and C. thespidioides ['desert sneezeweed'] (Compositae) are highly aromatic [the aroma has been described as "an objectionable odour"], and have been used as tobacco substitutes. The powdered leaves and seeds have been used as a snuff, for their ability to induce sneezing [hence their common names]. They also relieve inflammation of the eye, and treat coughs, colds and sore throats. In inland Australia, C. cunninghammii was sometimes scattered around campsites to repel ants (Cribb & Cribb 1981; Latz 1995). C. minima contains triterpenes (Rai et al. 1999).

Codonocarpus cotinifolius [Gyrostemon cotinifolius] (Gyrostemonaceae) ['kandurangu', 'desert poplar', 'horseradish tree'] may not technically be a tobacco or pituri substitute, but the roots are chewed as a narcotic in some drier regions of Australia; the leaves are also chewed to ease toothache [sometimes with **Acacia** cuthbertsonii bark] (Lassak & McCarthy 1990). The root often contains grubs which must be removed before consumption, as they have toxic properties (Bindon 1996). The plant contains the alkaloids (E,E)-codonocarpine and N-methylcodonocarpine (Buckingham et al. ed. 1994), and leaf essential oil contains benzyl cyanide and cochlearin (Lassak & McCarthy 1990).

Dendrocnide spp. (Urticaceae), particularly D. excelsa ['giant stinging tree'], are well known in n.e. Australian rainforests for the intensely painful and lingering stings that result from even light contact with the plants (Cribb & Cribb 1981; pers. comms.). The stings [which in the case of D. excelsa, contain *serotonin*, *acetylcholine* and *histamine*] are reputedly relieved by sap of the wild banana **Musa** banksii. The bark and leaves have been used externally by indigenous healers to treat rheumatism, or as a counter-irritant for stings (Lassak & McCarthy 1990). D. moroides [Laportea moroides] leaves and stalks have yielded the bicyclic octapeptide moroidin, which causes extended duration of pain from stings (Oelrichs et al. 1992); the stinging hairs also contain *serotonin* (Schneider et al. 1972). Although not a substitute for tobacco or pituri, at least one Dendrocnide sp. has been used as an unusual masticatory drug. In the early 1900's, ethnographer Walter Roth observed that "At certain of the corroborees on the lower Tully River [Queensland] some of the blacks will chew, and spit out again, the leaves of the 'stinging tree'. The immediate effect is apparently a condition of frenzy, in which the individual may take violent action on his mates, or perhaps more commonly produce in himself a grossly disgusting perversion of the alimentary functions which enables him to eat human excreta" (Low 1990). Well, what can I say to that...

Derris trifoliata var. macrocarpa (Leguminosae), as 'keni' [a name also applied to a variety of medicines], may have been smoked in pipes by the Kawadji of e. Cape York Peninsula. The herb is also sometimes called 'dynamite plant' (Peterson 1979; Thomson 1939). It was not made clear by Thomson whether this species was actually used in place of tobacco, or if it simply shared the same name [the Kawadji also call tobacco 'keni'] (Thomson 1939). The powdered root of D. trifoliata is known as 'derris dust', and has weak insecticidal properties (Cribb & Cribb 1981). Roots of D. urucu and D. utilis [from Brazil] are known to be toxic to cold-blooded animals, and the former has been found to contain rotenone [see **Lonchocarpus**] (Pinto 1955).

Gastrolobium laytonii (Leguminosae) ['kite leaf poison bush'] has been used in unclear ways as a psychotropic drug by some elders in the desert regions north of Kalgoorlie, Western Australia. It is known to be toxic to stock animals, and contains sodium fluoroacetate. Also known as '10-80', sodium fluoroacetate is used to poison dingos (Low 1990), and is extremely toxic (pers. comms.)! G. callistachys has yielded 3-carbomethoxy-2-methyl-β-carboline (Shulgin & Shulgin 1997) and N-methyl-*tryptophan* methyl ester (Husson 1985).

Geijera parviflora [G. pendula] (Rutaceae) ['wilga'] is used in inland n.e. Australia; leaves are baked and powdered, to be smoked with other 'narcotic' plants for ceremonial purposes. It is said to induce drowsiness and drunkenness. The leaves are also infused and taken both internally and externally as an analgesic, or chewed and put in cavities to relieve toothache. Plants are highly variable in chemistry (Lassak & McCarthy 1990). Some varieties are eaten by sheep, whilst other varieties are not. Leaves of 'unpalatable varieties' from Goondiwindi [s.w. Qld] and Jondaryan [s. Qld] yielded the coumarin dehydrogeijerin [c.0.214%]; leaves of a 'palatable variety' from Jondaryan yielded instead the coumarin geiparvarin [c.0.22%] (Lahey & MacLeod 1967), which has shown antitumour activity (Bocca et al. 2001). Leaf essential oils are also variable; one variety [from Eidsvold, Qld] yielded an essential oil containing mainly linalool and geijerene (Sutherland 1964); another variety is rich in phlor-*acetophenone* dimethyl ether (Lassak & McCarthy 1990). Gently oven-dried leaves, collected near Peak Hill [NSW], next to the Newell Highway in mid-February, gave mild but definite narcotic-like effects when smoked through a water pipe (pers. obs.).

Goodenia lunata (Goodeniaceae) ['ingulba ndarinya'] leaves are dried, broken up or crushed between stones and mixed with ash for chewing by the Alyawarra and western Arrante; considered a poor substitute for 'real' pituri. It is sometimes used to poison waterholes in order to more easily catch game (Latz 1995; Low 1990; O'Connell et al. 1983). What was thought to have been a Goodenia sp. was reported to be administered to babies by native women, as a soporific for long journeys. Unfortunately further data is lacking on the identity of the plant or the region of use (Cribb & Cribb 1981). G. varia has been reported to be given to babies in the same way (Lassak & McCarthy 1990).

Heteropogon contortus (Gramineae) ['bunch spear-grass'] has been chewed as a narcotic amongst tribes around Broome, Western Australia. In India, the roots are considered stimulant and diuretic, and used to treat rheumatism (Cribb & Cribb 1981). In Bengal, the distilled oil from the awns is given with betel leaf [**Piper** betle] to treat asthma; a paste of the plant is applied to bites from scorpions, rabid dogs or jackals (Pal & Jain 1989). The plant may be burned to repel mosquitoes (Bindon 1996).

Lomandra spp. (Xanthorrhoeaceae) have no known traditional psychotropic use, yet one modern psychonaut reported that an unidentified ornamental species had similar stimulant effects to some **Cyperus** spp. when smoked (Gerbil pers. comm.).

Pterocaulon serrulatum [P. glandulosum] (Compositae) ['toothed ragweed'] has been chewed as a low-quality tobacco substitute in the Derby region of Western Australia. It has a strong and pleasant apple-scent when crushed, which is inhaled to treat colds. The new growth after rain is considered the most medicinally potent. The leaves have yielded 0.1% essential oil, with unidentified constituents. P. sphacelatum is used for the same purposes, but is less potent as a tobacco (Aboriginal Communities 1988; Cribb & Cribb 1981; Latz 1995). This latter species has yielded 0.08% essential oil, containing 1.7% *elemicin*, as well as many other compounds, most unidentified (Aboriginal Communities 1988).

Stemodia lythrifolia (Scrophulariaceae) ['bunu bunu'] has been chewed with ash as a stimulant 'bush tobacco' in n.w. Australia; an infusion of the plant is applied externally to treat headaches (Lassak & McCarthy 1990; Low 1990). S. viscosa has reputedly been used to relieve insomnia (Cribb & Cribb 1981).

Streptoglossa odora [Pterigeron odorus] (Compositae) ['applebush'] is used by the Northern Warlpiri as a pituri substitute; it also treats colds and internal pains (Aboriginal Communities 1988; Latz 1995). The plant has been described as smelling like mouse faeces (Low 1990).

Trichodesma zeylanicum (Boraginaceae) ['ngurnungurnung', 'camel bush', 'cattle bush'] was once used as a 'bush tobacco' in Arnhem Land; the Ngarinyman used to prepare it by sun-drying, and smoked it in long-stemmed pipes called 'larwa' (Smith et al. 1993). It is similarly used by the Gunwinggu of Arnhem Land, though elsewhere it is only used medicinally, or not at all (Low 1990). In n. Western Australia, the plant has been decocted and applied to sores to aid in healing. In Africa, the root has been

used as an analgesic, and one tribe uses the leaves in brewing beer, to aid in proper fermentation (Cribb & Cribb 1981).

Incidentally, whilst we are still in Australia, flower buds of a Banksia sp. (Proteaceae) have been claimed anecdotally to be psychoactive when smoked (pers. comm.). Flower heads of B. integrifolia are occasionally made into an alcoholic beverage by some indigenous people in s.w. Australia, who soaked them in water and allowed the nectar to ferment slightly. The effects of the beverage were described by Walter Roth as "exhilarating, producing excessive volubility" (Low 1990). Some plants from the Proteaceae contain obscure tropane alkaloids (Griffin & Lin 2000).

In the early 1900's, Eucalyptus spp. (Myrtaceae) leaf blends [from E. cinerea (a 'stringybark'), E. citriodora ('lemon-scented gum') and E. dives ('broad-leaved peppermint')] were marketed as cigarettes in Australia ["Take a whiff of the gum forests into your home", to quote one advertising slogan of the time] (Cribb & Cribb 1981). No psychoactivity was hinted at, the cigarettes presumably appealing simply due to their aromatic properties. However, as any Australian would know, Eucalyptus spp. leaves are rich in volatile oils and would quite possibly burst into flame rather than burn slowly and evenly. Thus, I suspect these cigarettes would have been cut with other herbs out of necessity. In Tasmania, the 'cider gum' [E. gunnii] was tapped for its sap, which was left to ferment in the holes cut in the tree. The resulting tasty and potent alcoholic cider was very popular amongst both indigenous people and white settlers (Cribb & Cribb 1981; Low 1990). E. microtheca ['coolibah'] bark has been burnt to ash for chewing with pituri in s.e. Queensland (Low 1990). As noted in the *Chemical Index*, some Eucalyptus spp. are potentially useful in the synthesis of *mescaline* from syringaldehyde, though these trees do not actually contain *mescaline*, nor are they known to contain alkaloids. The required syringaldehyde is prepared by oxidation of lignin from E. diversicolor ['karri'], E. obliqua ['messmate stringybark'] or E. regnans ['mountain ash'] (see Amos 1964). One person performed a tlc assay on the heartwood of an unidentified Eucalyptus sp. growing in the US, and tentatively identified the presence of *DMT* (Trout pers. comm.); this has also been observed with tlc by another researcher as a main or sole alkaloid in "wood and bark of a common Eucalyptus" (Appleseed 2002), again, probably one growing in the US.

Dried flowers of the European Ulex europaeus (Leguminosae) ['gorse', 'furze'] growing in Victoria, Australia [where it is a noxious weed], have also been smoked by modern experimenters as a mild narcotic. The effects are similar to those of smoked broom flowers [see **Cytisus**] (pers. comms.; pers. obs.). U. europaeus has been found to contain *cytisine* and related alkaloids [such as anagyrine], though plants growing in New Zealand were low or deficient in alkaloids (White 1943b). As well as plants discussed elsewhere in this book, *cytisine* has been found in Ammodendron spp., Anagyris spp., Baptisia spp., Colutea spp., Eucresta spp., Hovea spp., Lamprolobium fruticosum, L. grandiflorum, Plagiocarpus axillaris, Strongylodon macrobotrys, Templetonia spp. and Thermopsis spp. (Rätsch 1998).

'Mountain tobacco' [Arnica montana; Compositae] is said to be a powerful and acrid narcotic, and has been used as a tobacco and snuff. Willow leaves and bark [Salix spp.; Salicaceae] have also been used as tobacco ['big star tobacco'] in N. America by many tribes; Navajo healers ['stargazers'] are known to smoke it in healing ceremonies (Cooke 1860; Winter 1998). Willows are known to produce salicylic acid, which is an analgesic, and natural precursor to aspirin. The leaves may be infused and drunk to treat nervous insomnia. Oenothera albicaulis (Onagraceae) ['white-flowered evening primrose'] is mixed by the Navajo with the 'wild buckwheat' **Eriogonum** umbellatum, and smoked before retiring to ensure good dreams, as well as good luck. Flowers of Erigeron canadensis and E. philadelphicus (Compositae), 'fleabanes', are smoked by the Ojibway as a hunting charm. Young leaves of hawthorn [Crataegus spp.; Rosaceae] and hazel [Corylus avellana; Corylaceae] have been used as tobacco substitutes, the former in the first World War, when they were also used as tea [see **Camellia**], and the seeds ground as coffee [see **Coffea**] (Bremness 1994; Winter 1998). *Phenethylamine* has been found in Crataegus arnoldiana, C. mollis and C. monogyna (Hartmann et al. 1972). In Quebec, French fur traders have been known to drink a beverage made from 'reindeer lichen', Cladina rangiferina [Cladonia rangiferina] (Cladoniaceae), when their tea supplies run out. In Alaska, Aleut hunters eat Cladina spp. "to maintain their wind" when climbing, and may also drink them in tea to relieve chest pains. In Alaska and w. Canada, the 'kidney lichen' Nephroma arctium (Nephromataceae) is taken as an infusion to give strength to someone in a weakened state (Sharnoff undated).

Native Americans have used a great variety of herbs ['kinnikinnick' – see **Arctostaphylos**] for smoking either alone, or mixed with tobacco, some of which are covered elsewhere in this book. Some not otherwise mentioned are 'quinine bush' [Garrya elliptica; Garryaceae], 'leadplant' [Amorpha fruticosa; Leguminosae], Antennaria microphylla, A. rosea (Compositae), 'sandwort' [Arenaria spp. – see below], 'barberry' [Berberis spp.; Berberidaceae], 'sweet birch' [Betula lenta; Betulaceae], 'ironwood' [Carpinus caroliniana; Betulaceae], 'wild comfrey' [Cynoglossum virginianum; Boraginaceae], 'yerba santa' [Eriodictyon californicum; Hydrophyllaceae], 'wahoo' [Euonymus atropurpurea; Celastraceae], strawberry [Fragaria virginiana; Rosaceae], 'sweet grass' [Hierochlöe odorata – see below], 'mountain laurel' [Kalmia latifolia – see below], mint [Mentha aquatica & M. spicata; Labiatae], 'blazing star' [Mentzelia pumila; Loasaceae], 'cicely' [Osmorhiza occidentale - see below; Umbelliferae], red raspberry [Rubus idaeus; Rosaceae], 'mullein' [Verbascum thapsus – smoked to clarify thought, and as a hunting aid; Scrophulariaceae], corn silk [from Zea mays; Gramineae], pine [Pinus spp.] and 'Prince's pine' [Chimaphila umbellata; Pinaceae]. In Venezuela, a tobacco chewing mixture called 'chimo' is used with an alkaline ash – as well as tobacco, **Pimpinella** ansium, **Myristica** fragrans, **Syzygium** aromaticum, opium [see **Papaver**], 'tonka bean' [Dipteryx odorata; Leguminosae – said to be narcotic; produces coumarin when fermented (Lewis & Elvin-Lewis 1977)], 'cocui' liquor [from Agave cocui – see *Methods of Ingestion*], vanilla [Vanilla planifolia fermented, partially ripe fruit; Orchidaceae], brown sugar [Saccharum officinarum; Gramineae] and Palicourea chimo (Rubiaceae) leaves are added to the quid (Cooke 1860; Rätsch 1998; Siegel et al. 1977; Winter 1998). Taken with cacao [see **Theobroma**] or 'arrowroot' [Maranta arundinacea; Marantaceae], vanilla was used in central America as an aphrodisiac (Rätsch 1990); infusions of vanilla by itself are also reputedly aphrodisiac. Vanilla is regarded as a CNS stimulant and has been used to treat hysteria, melancholy, convulsions, impotence and rheumatism, and to "increase the energy of the muscular system". Numerous other Vanilla spp. are used for the same flavouring and medicinal purposes, but they are generally inferior to the vanilla from V. planifolia. The most important chemical from the fermented pods, vanillin, has been reported to act as a stimulant, aphrodisiac, tonic, antispasmodic, carminative and androgen, as well as aiding "protein synthesis and muscle regeneration" (Lawler 1984). Alkaloids have been detected in V. planifolia, V. chamissonis and V. pompona (Lüning 1967).

'Yarrow' leaves [Achillea millefolium; Compositae] have been used as a tobacco substitute [see **Nicotiana**], and added to beer to make it more intoxicating (Cooke 1860). The Winnebago of N. America use the smoke to revive the unconscious (Kindscher & Hurlburt 1998), and the Ojibway smoke the flowers of A. millefolium and A. lanulosa ceremonially (Winter 1998). A. millefolium is also "consumed as a tea in support of the vision quest", and the Navajo chew the stem or drink a tea of it as an aphrodisiac (Rätsch 1990). Achillea spp. contain *thujone*. *Thujone* is also found in the 'oak mosses', Evernia prunastri and E. furfuracea (Usnaceae) (Hall 1973). 'Coltsfoot' [Tussilago farfara; Compositae] has been claimed to have been smoked to induce visions by British peasants in the middle ages. It has been smoked also as a tobacco mixer along with betony, rosemary, thyme, **Anthemis**/**Matricaria** and lavender [see below]; it is usually used medicinally for coughs and other respiratory complaints. It is now banned in some countries due to the potential dangers of its pyrrolizidine alkaloids [in degrees of exposure too high to represent practical human usage] (Chiej 1984; Forsell 1993; Mabey et al. ed. 1990).

The Ainu of Japan smoke the leaves of Daphniphyllum humile (Daphniphyllaceae) as a tobacco substitute (Lewis & Elvin-Lewis 1977). In Ladakh, India, Rheum emodi (Polygonaceae) is smoked mixed with tobacco (Bhattacharyya 1991). 'Foxglove', Digitalis purpurea (Scrophulariaceae), is sometimes smoked with hashish [see **Cannabis**] in India – taken in excess, it may cause "delirium, insensibility and convulsions" (Cooke 1860). The plant is highly toxic, and can kill, containing powerful cardioactive glycosides. 'Fahan tea' or 'faham tea', Angraecum fragrans [Jumellea fragrans] (Orchidaceae), is a parasitic plant on trees. The leaves, stems and flowers have been decocted or infused in Mauritius and Bourbon as a tea or coffee substitute with sedative and digestive stimulant effects; later it was briefly popular in England and France. Leaves have been used in cigar flavouring. In w. Africa, Angraecum spp. bulbs are used in aphrodisiac preparations. The orchid Aceras anthropophora is used in Algeria as a fahan substitute, 'faham d'Algérie', said to taste better and have the same effects. Both plants contains coumarin [see **Justicia**]. A. anthropophora has also been used as a stimulant in the Middle East, and sometimes is used to make salep [see Orchis spp. below] (Lawler 1984; Von Bibra 1855). In Cuba, the leaves of Eurya theoides (Theaceae) are used as a tea substitute (Lewis & Elvin-Lewis 1977). The common garden shrub Hydrangea paniculata 'Grandiflora' (Saxifragaceae) has been suggested as a smokable **Cannabis** substitute, with 1 cigarette [and no more] being a dose; however, as well as hydrangin [umbelliferone] and saponins the plant contains cyanogens, so unless HCN poisoning is your idea of a good time, this is not recommended (Gottlieb 1992; Siegel 1976).

MISCELLANEOUS NARCOTICS, NERVINES and APHRODISIACS

Tylophora erecta (Asclepiadaceae) sap is used by indigenous peoples around the coast of n. Queensland, Australia, to prepare a 'love potion' with aphrodisiac effects; the plant contains isoquinoline alkaloids which are derivatives of tylophorine (Buckingham et al. ed. 1994; Lassak &

McCarthy 1990). T. asthmatica roots and aerial parts have yielded phenanthroindolizidine alkaloids, as well as *skimmianine* as a minor alkaloid of aerial parts, and γ-fagarine as a minor alkaloid of roots (Etherington et al. 1977). Leaf and stem of T. paniculata [harv. Mar., Qld] tested positive for alkaloids (Webb 1949). The common 'pomegranate' tree, Punica granatum (Punicaceae), was associated with the love goddesses Aphrodite, Venus and Astarte [as well as being said to have grown from the blood of Dionysus], and its fruits believed to have aphrodisiac properties. A stimulating and aphrodisiac wine may also be made from the crushed fruits (Rätsch 1990). Iranian Zoroastrians use an infusion of the leaves and twigs, with **Ephedra** and milk, to prepare a 'haoma' substitute beverage [see also **Peganum**] (Flattery & Schwartz 1989). The fruit rind and bark are used medicinally to help expel intestinal worms, though they can be toxic and should be used with caution (Chevallier 1996). Side effects may include "vertigo, dimmed vision, great weakness and cramps in the legs, formication, convulsive trembling, etc." with higher doses causing "mydriasis, partial blindness, violent headache, vertigo, vomiting and diarrhoea, profound prostration, sometimes convulsions." With the bark, 7g decocted is considered a dose in TCM. Bark may contain 20% tannins and 0.5-1% alkaloids [pelletierine and its derivatives] (Keys 1976). The plant has been claimed to contain MAOIs, and the root bark to contain *DMT* (Rätsch 1992), but supporting data is lacking. The south-east Asian 'durian' fruit, from Durio zibethinus (Bombaceae), is considered a "powerful aphrodisiac" eaten when ripe and fresh. The inner portion of the 'coco-de-mer' fruit of the Seychelles, Lodoicea maldivica (Arecaceae), is also used as an aphrodisiac, but the belief in this property may simply stem from the clear sexual imagery of the phallic male inflorescence and the yonic fruit or 'nut' (Rätsch 1990).

Chenopodium ambrosioides (Chenopodiaceae) ['American wormseed'] is known as 'slah-sam' in Meghalaya, n.e. India, where the juice of the plant is used to relieve nervous tension (Neogi et al. 1989). In Nepal, it is known as 'alimah' and is considered to be protective; shamans there sometimes use it as a ritual shamanic incense in place of mugwort [see **Artemisia**]. It may be used to transform water into 'amrita' if none of the preferred plants are available [see Thysanolaena maxima below] (Müller-Ebeling et al. 2002). In Malawi, the leaves have been used as an ingredient of a snuff also containing **Securidaca** longipedunculata root, Annona senegalensis roots [see below], and leaves of Asparagus africanus [see below]. This snuff is used to induce trance (De Smet 1998). The anthelmintic seeds of C. ambrosioides bear an oil which contains ascaridol, geraniol, d-*camphor*, p-cymene and l-limonene (Nadkarni 1976; Perry & Metzger 1980). In Atacama, Chile, leaves of C. arequipensis ['coquilla', 'pariente de la coquilla'] are chewed as a coca substitute [see **Erythroxylum**]. Other herbs used as coca substitutes include Cordia nodosa (Boraginaceae) [fruits of the Mexican C. boissieri are reputedly 'inebriating'], 'tabaco chuncho' [Andes]; Couma macrocarpa (Apocynaceae), 'sorva' or 'juansoco' [upper Amazon]; Cydonia oblonga (Rosaceae), 'membrillo' [Atacama]; Lacmellea lactescens and L. cf. peruviana (Apocynaceae) [upper Amazon]; a Rosa sp. (Rosaceae) [Atacama]; and Stylogyne amplifolia (Myrsinaceae), 'coca silvestre' or 'jipina coca' [Río Putumayo] (Rätsch 1998). See also **Erythroxylum**, **Dodonaea**, and Sonchus oleraceus, Urmenentea spp. and Werneria spp. below.

'Larkspur' [Delphinium spp.; Ranunculaceae] have been used as narcotics, but are known to be quite toxic in excess [the young leaves and seeds most toxic]. The herbs can produce sedation [to the point of stupefaction], nausea and nervous system depression. Other symptoms may include contact dermatitis, nervous excitement, depressed respiration and circulation, abdominal pain, tingling skin and burning sensation in the mouth. The Cherokee say the root "makes cows drunk and kills them" (Covacevich et al. ed. 1987; Emboden 1979a; Foster & Caras 1994; Hamel & Chiltoskey 1975). In parts of n. India, leaves of D. brunonianum are given as a sacred offering. The alkaloid delphinine, found in many members of this genus, is apparently an antidote to Aconitum spp. (Ranunculaceae) poisoning (Nadkarni 1976). Aconitum spp. ['monkshood', 'wolfsbane'] generally act as narcotics, analgesics and nerve paralysers (Bremness 1994; Nadkarni 1976). In n. Japan, the Ainu used Aconitum spp. to make arrow poisons for hunting (Bisset 1976). Some Nepalese Shivaites smoke and drink Aconitum spp. A. ferox and A. napellus are known as 'aghori' and are used as intoxicants (Rätsch 1998, 1999a), and are also acknowledged in Indian medicines as being powerful and dangerous narcotics (Nadkarni 1976). The Nepalese consider Aconitum spp. ['biss'] to be protective, although their name for the plants means 'poison'. Shamans may drink a carefully-dosed tea of the leaves and/or flowers [harvested March to May] to enter a visionary trance; leaves may also be burned as a ritual incense (Müller-Ebeling et al. 2002). A. napellus contains alkaloids – mostly neoline and napelline, with traces of *ephedrine* and sparteine (Freudenberg & Rogers 1976). *Salsolinol* has been found in A. carmichaeli (Buckingham et al. ed. 1994). It must be stressed that these plants are highly dangerous! In China, Musella lasiocarpa (Musaceae) sap is used as an antidote to Aconitum spp., as well as "to alleviate drunkenness". The pseudostem and rhizome are reputedly sometimes used to make a wine (Liu et al. 2003), presumably similar to palm wine.

Melilotus officinalis (Leguminosae/Fabaceae), 'melilot', is a mild sedative which soothes headaches, muscle and nervous stress, and insomnia; it contains coumarins (Chevallier 1996). Lotus wrightii (Leguminosae/Fabaceae) ['deervetch', 'Wright's horn clover'] is used for hunting magic by the Navajo, who say it is a "life medicine"; the roots are added to beer by the Apache to make it more intoxicating (Rätsch 1998). L. corniculatus ['bird's foot trefoil'] flowers are sedative, and the whole plant has effects similar to **Passiflora** incarnata. Lotus spp. produce a cyanogenic glucoside, linamarin. Lycopus europaeus and L. virginicus (Labiatae), 'gypsyworts', are sedative narcotics with cardiotonic properties, the latter species being more potent (Bremness 1994; Chevallier 1996; Conn 1973). Roots of 'paeony', Paeonia officinalis (Paeoniaceae), have been used to treat epilepsy (Nadkarni 1976); they act as a nerve tonic and antispasmodic. In England, the seeds were once infused in mead to prevent nightmares. The plant is potentially toxic (Bremness 1994), and inhibits plasma AChE (Orgell 1963b). The root and its major constituent, paeoniflorin, have been shown to reverse *hyoscine*-induced performance deficits in rats (Ohta et al. 1993). In Nepal, water from the flowers of P. emodi is considered a form of 'amrita' (Müller-Ebeling et al. 2002). Potentilla fruticosa (Rosaceae) is known as 'bhairunga pate' in Nepal and has numerous magical associations; the leaves are used in incense (Müller-Ebeling et al. 2002). A Potentilla sp. may have been an ingredient in European 'witches' ointments' [see *Methods of Ingestion*] (Rätsch 1998; Robinson 1996). 'Silverweed', P. anserina, may be applied externally to relieve pain (Bremness 1994).

Root and trunk of Ceanothus americanus (Rhamnaceae), 'New Jersey tea', have been used by native N. Americans as a sedative antispasmodic. The stem-bark of 'crampbark' or 'cranberry bush' [not related to true cranberries - see **Vaccinium**], Viburnum opulus (Caprifoliaceae), has similar actions (Bremness 1994; Hutchens 1973). *Phenethylamine* has been found in V. lantana (Hartmann et al. 1972), and traces of *tyramine* in V. odoratissimum leaf (Wheaton & Stewart 1970). Hedera colchica (Araliaceae), related to the English ivy [H. helix], has shown narcotic and antispasmodic effects in mice and rats (Brussell 2004). H. helix itself has long been rumoured to be psychoactive, causing a kind of delirium, especially when added to wine [see *Methods of Ingestion*]. Dried leaves are said to be psychoactive when smoked. The berries, made into a drink, have been said to guard against inebriation. However, the identification of 'ivy' referred to in historical accounts is doubtful, and may in fact refer to plants of the Convolvulaceae [eg. see **Argyreia**, **Ipomoea**] with a similar appearance [at least when not in flower]. H. helix contains a variety of substances, including *chlorogenic acid*, hederatannic acid, malic acid, formic acid, hederasaponins, inositol, glycosides and the alkaloid emetine (Rätsch 1998).

In China, roots and leaves of the 'indigo plant', Indigofera tinctoria (Leguminosae/Fabaceae), are used to treat depression (Bremness 1994). In Mexico, I. suffruticosa is used as an analgesic and antispasmodic for epilepsy and abortion (Jiu 1966); it also has tranquillising properties (Heffern 1974). Indigofera spp. are used in parts of Asia to treat epilepsy, and some may produce stupor in excess (Watt 1967). I have found I. australis to be mildly sedative when smoked – it should be noted, though, that many Indigofera spp. are hepatotoxic and have caused stock poisonings (Keeler 1975). Seeds of I. endecaphylla contain indospicine, a hepatotoxic and teratogenic amino acid (Miller & Smith 1973). Leaf of I. australis [from NSW, Australia] was shown to contain 0.04% alkaloids in one screening (CSIRO 1990); all parts of plants growing in New Zealand [harv. Sep.] contained no alkaloids (White 1951). Canavanine [see **Canavalia**] has also been found in many Indigofera spp. (Bell et al. 1978).

Tropaeolum majus (Tropaeolaceae), 'nasturtium', is said to be a rejuvenating aphrodisiac [the whole plant taken]. The related T. tuberosum bears edible tubers, which are anaphrodisiac, lowering testosterone. The candied autumn roots of Eryngium maritinum (Umbelliferae), 'sea holly', were popular in the 18th century as a tonic and aphrodisiac (Bremness 1994), and the Indian E. caeruleum root is also used as an aphrodisiac and nerve tonic (Nadkarni 1976). 'Horseradish' [Armoracia rusticana (Brassicaceae) root, which sometimes may look like male genitalia, is used as an aphrodisiac and for "renewing strength after sexual exhaustion" (Rätsch 1990). Fruits of 'saw palmetto', Serenoa serrulata [Sabal serrulata] (Palmaceae), were eaten by native N. Americans as a nutritive tonic with sedative, diuretic, anabolic and oestrogenic properties. However, they are also regarded to be aphrodisiac and to treat impotence. In s. US, they have been taken in 'love potions', combined with Osmorhiza occidentalis ['sweet anise'] root [see below]. They contain steroidal saponins, 1-2% essential oil, fixed oil, tannins and polysaccharides. The seeds of Echium vulgare (Boraginaceae) ['viper's bugloss'] have been decocted and added to wine to "comfort the heart and drive away melancholy"; the roots are apparently used for the same purpose. A leaf infusion acts as a nerve tonic, as well as relieving fevers and inflammation. Today, it is considered toxic by some (Bremness 1994; Chevallier 1996; Cribb & Cribb

1981; Grieve 1931; Rätsch 1990). Young shoots and roots of Arctium lappa (Compositae), 'burdock', can be infused to make a "strengthening aphrodisiac tonic"; the root has shown mild anti-tumour activity. 'Tamarack' or 'Eastern larch', Larix laricina (Pinaceae), may be drunk as a "weak tea to treat melancholy" (Bremness 1994). In Nepal, L. griffithii ['Himalayan larch', 'bargay salla'] is sometimes used for incense by shamans (Müller-Ebeling et al. 2002). In S. Africa, the Zulu refer to a number of plants from different genera as 'uBangalala', generally used to treat impotency. One of these plants was identified as Eriosema kraussianum (Leguminosae), used for its roots. The roots yielded pyrano-isoflavones named kraussianones, which had varying degrees of activity on rabbit penile smooth muscle, comparable to that of Viagra™ (Drewes et al. 2002). In Cairo, Arachis hypogaea (Leguminosae) seeds ['pistache de terre', 'ground nut'] are sold to be eaten as an aphrodisiac (Martindale 1889).

Orchis spp. (Orchidaceae), whose twinned tubers resemble testicles [hence the genus name, from the Greek for testicle], have a reputation as aphrodisiacs, clearly deriving at least partly from symbolism. The aphrodisiac 'satyrion' consumed in Dionysian rites was apparently an Orchis sp., and satyrs were said to get their sexual energy from eating orchids; interestingly, some orchids [see below] contain caproic acid, which smells of goat. In Europe, O. maculata and O. latifolia tubers were used against impotence or sterility caused by witchcraft, whilst witches were said to use O. mascula ['early purple orchid'] tubers in love potions; they have also been used as aphrodisiacs for reluctant stock animals as well as for people. Numerous species have been used to prepare the Arab beverage 'sahlab' ['fox testicle'], bastardised as 'salep' once its use spread to Europe; in London it was popular with the working class before cheap coffee and tea became common. It was often prepared mixed with sugar, milk and spices. Salep has been credited with aphrodisiac, tonic, nutritive and restorative properties which are now held in doubt. In Turkey it is used to make ice cream, and it has even been used to adulterate opium. The preferred species used for salep are O. latifolia, O. mascula, O. morio ['green-winged meadow orchid'] and Platanthera bifolia, though many other Orchis spp. have been used, as well as tubers from other orchid genera. For use, the new tubers [of the paired tubers, one is shrivelled from the previous year] are gathered after fruiting, then washed, skinned and dried before being powdered. Tubers of 'false salep', O. lutea and O. provincialis, have been used as analeptics and aphrodisiacs in Algeria, and in the US O. fragrans tuber has been used as a nervine stimulant. O. maculata, O. mascula and O. militaris have been used as weaker substitutes for fahan tea [see Angraecum above] in France. In Pakistan and n. India, O. latifolia has been used as a nerve tonic. O. morio was regarded as an aphrodisiac by the ancient Greeks, and members of the genus in general were valued as such in the far east. Coumarin has been found in O. coriophora, O. galeata, O. militaris, O. purpurea and O. simia; Orchis spp. also yield a glucomannan [degrading to mannose and sucrose in spring], protein, and a mucilage containing calcium oxalate crystals (Lawler 1984).

Many other orchids have been used as aphrodisiacs, such as Cynorchis purpurascens [bulbs, Madagascar], Listrostachys sp. [bulbs, w. Africa], Polystachya sp. [bulbs, w. Africa], Coelogyne ovalis [ayurvedic preparations], Eria muscicola [ayurvedic preparations; E. japonica used as 'shih-hu' substitute - see Dendrobium below; alkaloids found in genus], Himantoglossum hircinum [Satyrium hircinum; contains caproic acid; genus also used to make salep], Microstylis wallachii [bulbs, India; alkaloids found in genus] and Ophrys linifolia [bulbs, Mediterranean; genus also makes salep] (Lawler 1984; Lüning 1967). Young Zulu men use Ansellia gigantea [A. africana; 'leopard orchid'] and A. humilis roots to make girls temporarily sterile, for obvious reasons, and the stem infusion is also said to be aphrodisiac. A. humilis is also used to relieve nightmares, either by drinking a stem infusion or burning the root and holding the head in the smoke, and a leaf and stem infusion treats madness. A. gigantea is grown as a fetish plant by Bwiti leaders in Gabon; the whole plant contains an alkaloid. In e. Africa, Eulophia angolensis root sap is drunk as an aphrodisiac, and in S. Africa men take it "to ensure success in courting"; root sap also treats earache. E. cucullata [Lissochilus arenarius; 'foxglove orchid'] is used by the Zulu as an infusion to treat "barrenness or impotence due to lack of nervous or muscular power", and in S. Africa the root is used as a stimulant. E. campestris root has been used as an aphrodisiac in India, as has E. lindleyana root juice in Africa. E. campestris, E. herbacea, E. nuda and E. virens have also been used as salep in n. India/n. Pakistan. E. virens has been reported to cause madness in cattle who eat it. Alkaloids have been detected in the genus. Stems of a Lissochilus sp. are chewed by men in Transvaal, for the strong erections that result when the juice is swallowed. In Madagascar, roots of L. madagascariensis are used as an aphrodisiac, and L. beravensis is used for nervous disorders. The S. African L. krebsii is used as a sedative (Burkill 1985-1997; Lawler 1984; Lüning 1967; Watt & Breyer-Brandwijk 1962).

In N. America, the orchids Habenaria dilatata and H. viridis have been used in food as a female aphrodisiac; H. viridis, H. media and H. saccata have been used as love charms. In India, H. commelinifolia and H. pectinata have been used as salep. Alkaloids have been found in the genus. Ipsea speciosa tubers are reputedly aphrodisiac in Sri Lanka, and sorcerers use them to make love potions and charms; in India they are used as a stimulant. Gymnadenia spp. are reputed to be aphrodisiac in Norway. In Europe, G. conopsea has been used to treat epilepsy and nervous disorders; this species and G. odoratissima have yielded coumarin. Bulbophyllum spp. tubers have been used as aphrodisiacs in w. Africa, and B. japonicum has been used as 'shih-hu' [see Dendrobium below]; B. auricomum contains coumarin, and alkaloids have been detected in the genus. In Europe Spiranthes autumnalis has been used as an aphrodisiac, and S. spiralis reputedly has the same effects; the genus has been used as salep, and alkaloids have been found. In Ambon, Indonesia, seeds of Grammatophyllum scriptum are given to women, who reputedly must puruse the person who gave it to them. In the West Indies, an alcohol tincture of Brassia caudata is used to treat epilepsy and nervous disorders. In the US, Corallorhiza maculata stalks and C. odontorhiza roots have been used for their sedative properties. Natives of California drank a root decoction of Epipactis gigantea to treat mania and severe illness; a report by Perry & Metzger (1980) of E. mairei fruit decoction being tonic and stimulating hormone secretion may be in error. Members of the genus have also been used to make salep. In the Philippines, Spathoglottis plicata leaves were smoked as a tobacco substitute following the Japanese invasion in World War II; an alkaloid has been detected in S. lobbii. In Malabar, Pholidota pallida fruit has been used as a narcotic for insomnia, and to relieve headache and earache; alkaloids were not found in 4 species tested (Lawler 1984; Lüning 1967).

In Florida, some indigenous tribes have used the roots of Lachnanthes tinctoria (Haemadoraceae) ['spirit weed', 'red root'], in the words of a Dr. Byron, "to produce a brilliancy of the eye, a flushed and swollen face, a bold appearance, and eloquent speaking; after these peculiar stimulating effects pass off, the person becomes stupid and very irritable." Large doses of the plant can cause visual disturbance, pupil dilation and dizziness; the effects of such large doses have been compared to those of **Atropa** belladonna. The roots are ordinarily used to produce a dye (Felter & Lloyd 1898). Comandra pallida (Santalaceae), 'bastard toadflax', is apparently used by the Kayenta Navajo of N. America as a narcotic (Ott 1993). The related parasitic C. umbellata is used by the Cherokee steeped with **Cypripedium** acaule for kidney problems, and the juice of the plant is applied externally to wounds (Hamel & Chiltoskey 1975). Some tribes also use the sweet fruits as food (Usher 1974). Chemistry of these plants is obscure.

Adenanthera pavonina (Leguminosae/Mimosaceae) ['coralwood', 'red sandalwood', 'bead tree'] [note – *not* **Anadenanthera**] is a widespread tree in tropical zones; its shiny, red, uniform seeds are often used as necklace beads, and have been used as weights by jewellers and apothecaries. They may be roasted and eaten, but the raw seeds are said to be intoxicating. In India, the seeds are powdered to use as a plaster for soothing boils and headache, and are also sometimes used to treat paralysis. A leaf decoction is said to act as an aphrodisiac if used for any extended period. The wood is decocted as a tonic (Bremness 1994; Cribb & Cribb 1981; Kirtikar & Basu 1980; Nadkarni 1976; Patel et al. 1947; Watt & Breyer-Brandwijk 1962). The seeds contain c.14% oil, of which 25% is lignoceric acid, as well as O-acetylethanolamine, galacticol, β-sitosterol, stigmasterol, 2-amino-4-ethylidenepentanedioic acid, 2-amino-4-methylenepentanedioic acid, γ-methylene-*glutamine*, γ-methylene-*glutamic acid*, γ-ethylidene-*glutamic acid* and 1H-imidazole (International... 1994; Kirtikar & Basu 1980; Krauss & Reinbothe 1973); the leaf has yielded an alkaloid [from the 2.25% residue of the alcohol extract], which was not identified (Patel et al. 1947). Caution should be exercised with the seeds of this plant, as the nature of their "intoxicating" properties is unclear.

The guava tree [Psidium guajuva; Myrtaceae] has been decocted as an effective opium substitute; leaves or bark may be used, the latter being stronger in action. In coastal Ghana the leaves are chewed for "a central effect", as well as to treat insomnia and lessen the effects of alcohol. In many countries it is used to treat toothache, convulsions and gastric complaints (Lutterdodt & Maleque 1988; Perry & Metzger 1980; Rätsch 1998). The inner stem bark has yielded amritoside, leucocyanidin and egallic acid; leaves have yielded an essential oil, tannins, amritoside, leucocyanidin, guaijaverin, guaijavolic acid, crategolic acid, maslinic acid, egallic acid and quercetin. Flavonoid compounds appear to play a large role in the narcotic activity observed in mice after administration of the leaf extract, both i.p. and orally (Lutterdodt & Maleque 1988; Seshardi & Vasishta 1965a, 1965b). Numerous Latin American plants have common names indicating some relationship with opium poppies ['amapola'; see **Papaver**], though it is not known if they are used as opium substitutes. These include Althaea rosa (Malvaceae), 'amapola grande' [also known more commonly as 'hollyhock'; A. officinalis is the common 'marshmallow']; Hunnemania fumariaefolia (Papaveraceae), 'amapola'; Kosteletzkya paniculata (Malvaceae), 'amapola'; and Pseudobombax ellipticum [Bombax ellipticum] (Bombaceae), 'amapola', 'amapola blanca' or 'amapola colorada', 'amapola silvestre'. Another plant from the Malvaceae, Malva rotundifolia, has been reported from Afghanistan to

have inebriating seeds (Rätsch 1998). Chelidonium majus (Papaveraceae) has been known as 'hexenmilch' ['witch's milk'] and 'hexenveilchen' ['witch's violets'] in Germany (De Vries 1991), and as 'amapola amarilla' ['yellow poppy'] in Latin America (Rätsch 1998). C. majus alkaloid extract modulated binding to the *GABA*a receptor, enhancing the binding of *muscimol* (Häberlein et al. 1996). The plant has yielded *tyramine* (Smith 1977a), *protopine*, allocryptopine, chelerythrine, chelidonine, magnoflorine, sanguinarine, sparteine [see **Cytisus**, **Lupinus**] and numerous other alkaloids (Preininger 1986). See also **Argemone**, **Eschscholtzia**, **Ipomoea**, **Passiflora**, and Bernoullia flammea and Tabebuia below.

Annona palustris (Annonaceae), 'alligator apple', is said to be narcotic (Bremness 1994). In some parts of Africa, A. senegalensis root is used as a homicidal poison; the root bark contains diterpenes (De Smet 1998). The related 'soursop', A. muricata, has been shown to contain *GABA* (Durand et al. 1962), and *salsolinol* is found in A. reticulata (Buckingham et al. ed. 1994). Seeds of A. atemoya, a Taiwanese species, have been found to contain N-behenoyl-*tryptamine*, N-cerotoyl-*tryptamine*, N-lignoceroyl-*tryptamine*, N-nonadecanoyl-*tryptamine*, N-octacosanoyl-*tryptamine*, N-tricosanoyl-4,5-dihydroxytryptamine, N-lignoceroyl-4,5-dihydroxytryptamine, N-pentacosanoyl-4,5-dihydroxytryptamine, N-heptacosanoyl-4,5-dihydroxytryptamine, the non-indole alkaloids artemoine and cleistopholine, and a variety of acetogenins (Wu et al. 2005).

The wood of the 'box shrub' [Buxus sempervirens; Buxaceae] is narcotic and sedative – the plant is considered toxic (Bremness 1994), and inhibits plasma AChE (Orgell 1963b). In Tuscany, Italy, branches are kept in the trousers to prevent the 'evil eye' (Pieroni & Giusti 2002). Actaea alba ['white cohosh'] and Cimicifuga racemosa (Ranunculaceae) ['black cohosh'] of N. America have been used as nerve tonics to 'relax hysteria'; the whole plant of the former, and only the root of the latter, being used (Emboden 1979a). C. racemosa is known to be antispasmodic and sedative (Bremness 1994). Common 'sow-thistle' [Sonchus oleraceus; Compositae] has even been found to be an effective opium substitute when boiled and drunk (Emboden 1979a); in Australia, some Victorian indigenous tribespeople say the leaves can induce sleep (Low 1990). So far, no alkaloids have been found, but flavonoids [incl. *apigenin*] and phenolic acids [incl. *chlorogenic acid*] have been detected; the coumarins aesculetin [see **Aesculus**] and chichoriin have been found in some species (Giner et al. 1993). As 'wirikocha', it is chewed as a coca substitute [see **Erythroxylum**] in Atacama, Chile (Rätsch 1998).

The fruits of Salpichroa origanifolia [S. rhomboidea] (Solanaceae) are considered narcotic, producing "symptoms of drunkenness" when consumed in large quantities. The roots yielded small amounts of tropine, pseudotropine, hygrine, cuscohygrine, and possibly *hyoscyamine* (Evans et al. 1972a). Rhizome and roots of the N. American 'skunk cabbage', Symplocarpus foetidus (Araceae), have stimulant, narcotic, antispasmodic and emetic properties; in large doses, the roots and seeds can also cause vertigo, dim vision, nausea, vomiting and headache. It has been used to treat hysteria and epilepsy, amongst other things. *Serotonin* is one of the leaf constituents. The roots cause intense itching and inflammation on skin contact. The related Arisaema draconitum (Araceae) ['green dragon', 'dragon root', 'owl's foot'] is used in sacred bundles, to give the owner of the bundle "the power of supernatural dreams" (Croat 1994; Hutchens 1973; Plowman 1969; Schmidt 1984; Schneider et al. 1972). It is reputedly 'hallucinogenic', and the Ojibway "are said to have used the root to counteract witchcraft". The plant is rich in calcium oxalate crystals that can cause an allergenic reaction when touched or eaten (Rätsch 1998). Nepalese shamans regard Arisaema spp. ['gurbo', 'banko', 'cobra lily'] as potent plants for shamanic travel and spiritual teaching [usually A. griffithii and/or A. utile], although they are very dangerous and rarely used. Mere skin contact can be enough for effects to manifest - generally, violent vomiting, trembling, cold sweat and swollen tongue, although shamans are propelled into a trance. When taken internally by shamans, a small piece of root [5mm diam.] is first cooked with salt and **Zanthoxylum** piperitum fruit to detoxify it. The fruit of Arisaema spp. is considered food for 'nagas' [see **Naja and Ophiophagus**] (Müller-Ebeling et al. 2002).

Isatis tinctoria (Cruciferae), 'woad', may promote psychic sensitivity if taken regularly, though it is slightly toxic (Trout & Friends 1999). Flowers of Primula veris (Primulaceae), 'cowslip', are sedative and antispasmodic, with antihistamine actions; the roots contain salicylic acid-related compounds. Dried aerial parts of Pulsatilla vulgaris (Ranunculaceae), 'pasqueflower', are sedative, antispasmodic, analgesic and nerve tonic; the plant is considered toxic when fresh (Bremness 1994). P. alpina ssp. apiifolia flowering aerial parts were found to contain protoanemonin and anemonin, which have sedative properties [see **Clematis**, **Ranunculus**] (Martin et al. 1988). Lamium amplexicaule (Labiatae/Lamiaceae) ['deadnettle', 'henbit'] has caused a form of 'staggers' in stock animals in Australia, which is apparent when the animals are forced to move (Webb 1948).

Myrica gale (Myricaceae), 'bog myrtle' or 'sweet myrtle', is an aromatic shrub which has been used in brewing beer [see *Methods of Ingestion*], and to flavour alcoholic spirits. In beer, it acts as a preservative, flavouring, and narcotic. It was well known as an ingredient of 'gruit' beer, popular in Europe [including Britain and Scandinavia] before hops [see **Humulus**] became the legislated brewing herb [though enjoying a brief revival in European ales during World War II]. Gruit, although having many regional variations, consisted primarily of M. gale, 'yarrow' [see above], and **Ledum** palustre, as well as various other herbs and spices [including **Cinnamomum**, **Pimpinella**, **Myristica** fragrans, ginger (see below)], and was known to be particularly intoxicating and aphrodisiacal. In Scandinavia, braches of the plant [M. gale] were once situated in the home to repel evil spirits and attract good fortune. The whole plant contains an essential oil, and flavonoids related to the chalcones (Buhner 1998; Rätsch 1999b; Simpson et al. 1996). In e. Africa, M. kilimandscharica and M. salicifolia ['ol getalasu'] barks are used with other barks and roots [see **Acacia**, *Methods of Ingestion* and Albizzia spp. below] by the Masai as strong stimulant-excitants (Lehmann & Mihalyi 1982). Lichens have also sometimes been used in brewing beer. Lobaria pulmonaria [Sticta pulmonaria] (Stictaceae/Lobariaceae), often called 'lungwort' due to its appearance, has been used as such in place of hops in Siberia and Europe; it is also sacred to the Sechelt of British Columbia. Some monasteries in Russia and Siberia were known in the past for the "highly intoxicating" lichen-fortified beer they served to travellers, suggesting that the lichens are added not only for their bitter properties. In the Great Lakes region of N. America, the Menomini eat L. quercizans [S. glomulifera] growing on maple or hemlock trees, taking it in soup as a tonic medicine (Sharnoff undated).

Hibiscus spp. (Malvaceae) seeds are considered aphrodisiac in India (Nadkarni 1976). In Colombia, Paez shamans chew H. abelmoschus ['ush ni'in', 'culebrina', 'musk seed'] seeds with coca [see **Erythroxylum**], for their pungent aromatic flavour, and "potent magical charge"; medicinally, the seeds have nervine and stomachic effects (Antonil 1978). H. esculentus is an ingredient of a w. African millet beer called 'dolo', also containing **Acacia** camplyacantha, 'balanos' [Balanites aegytica], **Datura** stramonium seeds, and **Grewia** flavescens as additives [see *Methods of Ingestion*] (Rätsch 1992). Root bark of H. syriacus contains coumarins [such as *scopoletin*] with MAOI (Yun et al. 2001) and other properties [see *Chemical Index*].

Borago officinalis (Boraginaceae), 'borage', has been claimed to "make men and women glad and merry, to comfort the heart, dispel melancholy and give courage". Dioscorides and Pliny also claimed it was an ingredient of the 'nepenthe' wine mentioned in Homer's 'Oddysey', which brought "absolute forgetfulness" [see below]. The herb is a mildly analgesic adrenal tonic, as well as being a diaphoretic, antipyretic, emollient, expectorant and emmenagogue; the seed oil ['starflower oil'] is used for menstrual irritability (Bremness 1988, 1994; Chiej 1984; Mabey et al. ed. 1990; Ody 1993).

A commercially-available tincture said to be prepared from the 'California pitcher plant' or 'nepenthe' has been reported by one person to have 'disorienting' and 'mildly hallucinogenic' effects when taken at low doses. However, the identity of the plant is uncertain, as its common name may represent both Darlingtonia californica and Sarracenia purpurea [both Sarraceniaceae]. Nepenthes spp. [Nepenthaceae], another group of pitcher plants, might have similar effects (pers. comms.). Sarracenia flava has been found to produce *coniine* (Mody et al. 1976), so extra caution is advised when experimenting with these plants (pers. obs.). 'Nepenthes', as mentioned above, was the name of a drugged wine given to Helen as described in Homer's 'Odyssey', which caused her to forget her home after being abducted. Its actual identity has been long disputed, and will probably never be known with any certainty (Rätsch 1998).

The common 'snowdrop', Galanthus nivalis (Amaryllidaceae), has been convincingly proposed to have been the mysterious herb 'moly' of ancient Greek mythology. In Homer's 'Odyssey', the crew of Odysseus' ship were turned into pigs and made to forget their past by Circe, who had given them food laced with poisonous herbs. The descriptions strongly suggest the anticholinergic effects of Solanaceous plants such as **Atropa**, **Hyoscyamus** and **Datura**. Odysseus was given the herb 'moly' by Hermes, so that he would be able to resist the effects of Circe's drugs, and thus rescue his men. Botanically and pharmacologically, all fingers seem to point to G. nivalis as the identity of moly, which contains *galanthamine*, an alkaloid with anticholinesterase activity, which has been shown to be useful to produce "a safe and effective reversal of the central anticholinergic syndrome in man" (Plaitakis & Duvoisin 1983). Incidentally, Amaryllis vittata from the same family is rich in synephrine [see **Citrus**], yielding 0.0223% [w/w] from leaves, along with 0.008% *tyramine*, 0.0058% N-methyltyramine and <0.0001% octopamine; bulbs yielded much smaller quantities (Wheaton & Stewart 1970).

RHODODENDRONS and OTHER ERICACEAE

Rhododendrons of the genera Rhododendron and Azalea are known to have narcotic properties. The Siberian R. chrysanthemum is quite powerful, and the leaves have been used safely by humans. In some hill regions

of India, flowers of R. arboreum may be chewed as a narcotic when no others are available. In the Himalayas, dried ripe leaves may be used; young leaves are considered toxic. In Nepalese Himalaya, R. anthopogon var. hypenanthum, R. cinnabarinum, R. lepidotum and other Rhododendron spp. ['sun pati'] are burnt as ritual incenses; leaves, branches and/or flowers may be used. In Burma, R. moulmainense is known to be narcotic and stupefying, as is the honey made from it. However, in Tibet some eat it without harm. The N. American R. maximum is also considered narcotic and stupefying. In Papua New Guinea, R. macgregoriae ['womp'] is used to disperse the 'spell of death', and causes emesis and purging. In Japan, Rhododendron spp. leaves are used in folk medicine to treat hypertension. The fumes of these plants were reputedly inhaled by followers of Elijah amongst the Ossets of Caucasus, causing them to fall unconscious and experience prophetic dreams. Honey made from these genera is known to be toxic, having been responsible for many non-fatal poisonings in the past [from c.50-100gm of honey]. Symptoms begin 3-4 hours after ingestion with vertigo; this subsides, but returns periodically in more and more intense bouts, accompanied by vomiting, mental excitation, delirium, sometimes convulsions, followed by coma, after which subjects recover; in some cases there is no recovery, and death results from central paralysis. The species often responsible are R. ponticum [A. pontica] and R. luteum. The chemicals responsible are terpenoid glucosides called andromedotoxins [grayanotoxins], asebotoxins, rhodojaponins and lyoniatoxins [lyoniols], known from many toxic Ericaceae. Leaves of some species may contain, on average, 0.01% andromedotoxins. Grayanotoxin was also found in R. albiflorum, R. macrophyllum and R. occidentale. Extracts of the leaves of R. brachycarpum and R. metternickii var. pentamerum, administered to mice and rats regularly at doses of up to 0.25mg/kg per day [p.o.], did not reveal apparent toxicity, though 1mg/kg, 1/5 of the expected LD50, did cause some deaths. Other related plants of the family Ericaceae share narcotic and toxic properties. Kalmia angustifolia is narcotic; the sap has yielded grayanotoxin, dihydrochalcones such as phlorizin and phloretin, and 2',6'-dihydroxy-4-MeO-*acetophenone*. Grayanotoxin was also found in K. polifolia var. polifolia and K. polifolia var. microphylla. K. latifolia has yielded hyperin [see **Hypericum**], phlorizin and ursolic acid. Fruits of the Bolivian Befaria kindeniana [B. glauca var. coarctata], 'macha macha', cause 'dizziness and distress', as well as strong stimulation if used over time. The leaves of Andromeda polifolia are also known to be narcotic (Constantine et al. 1967; Cooke 1860; Festi & Samorini 1996; Hikino et al. 1979; Mancini & Edwards 1979; Müller-Ebeling et al. 2002; Ott 1993; Palmer-Jones 1965; Perry & Metzger 1980; Rätsch 1999a; Sakakibara et al. 1978; Stopp 1963).

The fruits of the 'strawberry tree' [Arbutus unedo] from N. America and Europe have been made into a narcotic wine (Emboden 1979a); they are said to be narcotic alone if consumed in large quantities (Bremness 1994). In Mexico, Arbutus spp. are generally known as 'madroño', and are considered to be narcotic (Jiu 1966). A. menziesii ['madroño borrachero', 'tomazquitl'] is hypnotic, and was used by the Aztecs, with other herbs, to dispel fatigue (Heffern 1974). In Nepal, Lyonia ovalifolia ['angeri'] has been used as a smoking herb by Kirati shamans to increase their spiritual energy; the leaves ['angeri kopat'] are used as a wrapping for 'bidi' or 'biribiri' cigarettes [see **Nicotiana**, and Shorea below], and also as a filling when that role is not taken by tobacco or **Cannabis**. The effect of smoking angeri is reported to be strong and *nicotine*-like (Müller-Ebeling et al. 2002). In China, the leaves and fruits have been used as a tonic. Otherwise, the plant is considered toxic, and has yielded andromedotoxin; L. ovalifolia var. elliptica has yielded lyoniatoxin from leaves and lyoniols A-C from sprouts (Perry & Metzger 1980).

Erica spp. ['heather'] were used for centuries throughout much of Europe in brewing beer and mead [see *Methods of Ingestion*], though their use was best known from Scotland. In the British Isles, their use is at least 4,000 years old. Heather is thought to have been an important plant to the Druids, used for sacred fermented beverages. The Picts also used it ceremonially, and revered those responsible for the brewing process. Honey from heathers is highly nutritious, and high in protein. European species that have been commonly used include E. cinera ['Scotch heather'], E. vagans ['Cornish heather'], E. vulgaris ['ling' or 'broom heather'] and E. tetralix ['cross-leaved heather', 'bell heather']. Flowering tops are the parts used in brewing, and must be used soon after harvesting, as they lose their aroma quickly. They are sedative and mildly narcotic. A white powdery moss known as 'fogg' grows on the stems of species such as E. vulgaris and E. tetralix. This moss [botanical identity not known to me] has "narcotic and mildly hallucinogenic properties", and is host to a yeast that aids fermentation. Heather ale made from thoroughly washed tops is commercially available, though it may be difficult to find (Buhner 1998). E. lusitanica has been shown to contain 4-MeO-*phenethylamine* (Smith 1977a).

BAMBOOS (Gramineae)

Roots of black bamboo [Phyllostachys nigra] are apparently sometimes used as an anxiolytic (Bremness 1994). Another bamboo, thought to be an Arundinaria sp., is known as 'nigalo', 'tama' or 'ringal bans' in Nepal, and its shoots have been consumed for shamanic travel and learning of secret knowledge by some Kirati shamans, who say they learnt of it from the bear. Shamans also use it for strength, mixed with ginger [see below]. The best shoots are believed to be of 7 sections, and the top 4 are cut leaving 3 behind; this 4-section piece represents one dose. Before its use was known, another author had identified nigalo as being either Drepanostachyum intermedium or Thamnocalamus spathiflorus. If actually an Arundinaria sp., this is most likely to be A. racemosa [A. maling], as it is the only species of Arundinaria recorded in Nepal. One shaman stated that "all types of bamboo can become a spiritual binoculars or spiritual microscope", and to the Kirati, bamboos are sacred also because of their many uses in making things, including musical instruments and ritual paraphernalia (Müller-Ebeling et al. 2002; Rätsch 1999a; Stapleton 1994). In China, leaves of the bamboo A. densiflora are used as a stimulant, tonic and anthelmintic; leaves and rhizomes of A. amabilis are also considered tonic. Joints and culms of some bamboos of the genus Bambusa contain high concentrations of nearly pure silicic acid – this is known as 'tabashir', and was held in high esteem by ancient peoples. It has been used to treat nervous disorders, paralysis, childhood epilepsy, rheumatism and catarrh, and is stimulant, aphrodisiac and antispasmodic. The leaves of B. arundinacea are also considered aphrodisiac and antispasmodic. It should be noted that some bamboo shoots yield cyanogenic glycosides, which may be removed by parboiling at least three times, rendering the shoots edible (Chevallier 1996; Culvenor 1970; Nadkarni 1976; Perry & Metzger 1980). Some bamboos [eg. Phyllostachys reticulata] contain *serotonin* (Smith 1977b). Phyllostachys spp. leaves contain alkaloids, coumarins, steroids, saponins, triterpenoids, anthraquinones, glucosides, reducing sugars, proteins, amino acids, organic acids and tannins; flavonoids are also found in some species (Zhou 1992). Some bamboos may be infected by fungi, such as the Nepalese Cavimalum indicum (Clavicipitaceae), 'nigalo phoke cyau', of unknown chemistry and activity (Müller-Ebeling et al. 2002).

EUPHORBIACEAE

Some Euphorbiaceae are said to be psychoactive, though the latex that they bear is frequently toxic, and should not be brought into contact with eyes. Mildbraedia fallax is said to be narcotic, emetic, purgative and irritant [contains methylamine]. Euphorbia convolvuloides, E. helioscopia, E. pubescens and E. tiruealli are also said to be narcotic (Watt 1967). E. hamata is fed by Afrikaaners to their tired oxen, to give them renewed strength and vigour (Jacobsen 1960). Roots of E. davyi and E. decussata have been used in southern Africa to make indigenous beers or meads; pieces of the root are soaked and rinsed a few times before being added to the brewing process, and are said to greatly increase the strength of the finished beverage (Hargreaves 1999). In Israel, E. hierosolymitana is known to be narcotic. The latex has been used in traditional healing to treat "excessive libido", and is applied to wounds and warts; the seeds are decocted to treat depression and fear (Palevitch et al. 1986).

In s.e. Asia, E. hirta is decocted as an anticonvulsant, and also has mild narcotic properties (Perry & Metzger 1980). It has shown anxiolytic activity in mice, as well as sedative activity at high doses (Lanhers et al. 1990). In the Philippines, the leaves are smoked with those of **Datura** metel in cigarettes for asthma (Perry & Metzger 1980). In Germany, Euphorbia spp. have been known as 'hexenkraut' ['witch herb'], 'hexenküglein' [roughly 'witch droppings' (?)] and 'hexenmilch' ['witch milk'] (De Vries 1991). In some parts of Africa, E. balsamifera, E. kaokoensis, E. poissonii, E. subsala, E. tirucalli, E. trigona and E. unispina are used for their latex as homicidal poisons (De Smet 1998).

In India, the seed-capsules of E. lathyrus "are used to intoxicate" (Nadkarni 1976). *L-DOPA* has been found in the latex of E. lathyrus [1.7% w/w] and E. dendroides (Adinolfi 1966; Liss 1962). In Nepal, E. pulcherrima ['lalu pate'] leaves are used in ritual incense. In Nepal Phyllanthus emblica is the sacred 'amala' tree, which is considered a form of 'amrita' and is used in ceremonies, though it is unclear whether it is ingested (Müller-Ebeling et al. 2002). In Brazil, the Makú use P. brasiliensis to stupefy fish (Prance 1972). Some Phyllanthus spp. contain *securinine*-type alkaloids, such as P. discoides, which yielded 0.4% from root bark, 0.2% from stem bark and 0.06% from leaf (Bevan et al. 1964).

In Peru, the Shipibo-Conibo give a tea of an unidentified Euphorbia sp. ['curo', 'ai curo'] to apprentice shamans, "to improve the view during the ayahuasca intoxication" [see **Banisteriopsis**], as well as to "ameliorate the voice to sing icaros and taquinas" (Trout ed. 1998 citing Amazonia Peruana 5(10):91-118 [1984]). In Brazil, the Makú use E. cotinifolia to stupefy fish (Prance 1972). In Peru, this species [as 'timora'] is reportedly sometimes taken with San Pedro [see **Trichocereus**] (Davis 1983; Rätsch 1998), as are the Euphorbiaceous Pedilanthus tithymaloides ['cimora misha'] and P. retusus [P. tithymaloides ssp. retusus; 'misha' – see **Brugmansia**] (Davis 1983; Rätsch 1998; Schultes 1967a). In Lima, Peru, P. retusus is reputed to be a 'strong hallucinogen' and to contain a *mescaline*-like substance (Rätsch 1998). Members of the genus have a reputation for protecting against sorcery (Rätsch 1992). As 'Japanese poin-

settia', 'devil's backbone', 'redbird flower' or a variety of other colloquial names, P. tithymaloides is a horticultural plant which sometimes causes poisonings due to its irritating latex. The toxicity of oral ingestion is apparently low, though symptoms such as irritation of the mouth and throat, vomiting and diarrhoea have been observed (Russell et al. 1997).

The dried root of Manihot anomala ssp. anomala, 'sienejna', is reportedly smoked by Ayoreo shamans in Paraguay to contact the spirit realm; however, some Ayoreo say it doesn't work, and bioassays have been negative for any psychoactivity (Rätsch 1998). This genus is better known for 'manioc' or 'cassava', M. esculenta, which is used for its starchy root to make alcoholic beverages [see *Methods of Ingestion*].

MISTLETOES (Loranthaceae)

European mistletoe [Viscum album], a parasitic plant growing on various trees, has yielded 1-ethyl-*tryptamine* [pharmacology unknown] (Shulgin & Shulgin 1997), *phenethylamine*, *tyramine* [tentative] (Smith 1977a), *acetylcholine*, *choline*, *histamine*, viscalbine, viscoflavin, viscotoxins [polypeptides], glycoproteins, lignans [eg. syringin, eleutheroside E – see **Eleutherococcus**], flavonoids, inositol, mannitol, saponins, resins and vitamin C. It is a sedative, hypnotic, anxiolytic, antispasmodic, hypotensive, vasodilator, heart tonic, immune stimulant, emetic, purgative and antiseptic; medium and large doses depress the respiratory system. It also has some tumour-inhibiting properties, and is toxic in large doses (Bremness 1994; Bruneton 1995; Chevallier 1996; Chiej 1984; Nadkarni 1976). The plant was sacred to the Druids, who harvested it in autumn, or particularly Mid-summer's day, with a gold-bladed sickle [in one stroke, without the herb touching the ground]. They used 16 basic herbs for healing, with mistletoe being the one extra added to all preparations. Mistletoe growing on oak [Quercus spp.] was favoured, oak being one of their most sacred trees [see also **Castanopsis**]. In the preparations, it was to act as an "energy catalyst, to trigger the healing power of the herb". It has been associated with fertility and protection from evil (Cunningham 1994; Monroe 1992; Rätsch 1992, 1998). In Germany, it has been known as 'hexenkraut' ['witch's herb'], 'hexenast' ['witch's branch'], 'hexenbeere' ['witch's berry'], 'hexenbesen' ['witch's broom'], 'hexenbusch' ['witch's shrub'], 'hexennest' ['witch's nest'], 'hexenstock' ['witch's stick'] and 'hexenstrunk' ['witch's stalk'], pointing to a long association with magical practices (De Vries 1991).

Another mistletoe, V. cruciatum, is used as an epilepsy remedy in Morocco, yet locals believe ingestion of only one twig can cause madness (Watt 1967). In southern Africa, V. capense stems have been used by Europeans to treat epilepsy and St. Vitus' Dance [see **Claviceps**]. The Hottentot regard Viscum spp. as sacred, and use them to prepare an aphrodisiac (Watt & Breyer-Brandwijk 1962). In India, V. articulatum has been used as an aphrodisiac (Cribb & Cribb 1981). Some Voodoo cults consume V. album together with the mistletoe Phrygilanthus eugenoides; this latter plant is also said to be psychoactive. It is used as an ayahuasca additive [see **Banisteriopsis**, *Methods of Ingestion*] by the Culina and Sharanahua of Peru, as 'ko-ho-bo' or 'miya' (Pinkley 1969; Rätsch 1998; Rivier & Lindgren 1972).

In India, the mistletoe Loranthus falcatus is chewed as a narcotic betel nut substitute [see **Areca**]. Bark of L. longiflorus treats mania, amongst other conditions. L. monoicum is used as a **Strychnos** substitute (Nadkarni 1976). The Kalahari Bushmen may possibly use L. oleaefolius ['chichi'] to aid in reaching trance states for healing (Rätsch 1992). In Zimbabwe, L. spp. growing on Vitex payos [see below] are consumed to 'arouse spirits' (De Smet 1998). In Tanganyika, a Loranthus sp. is used in witchcraft, and a s. Rhodesian species growing on Ficus spp. [see below] is used as a poison (Watt & Breyer-Brandwijk 1962). A mistletoe growing on the Malpighiaceous shrub Acridocarpus spectabilis [see below] is macerated to prepare a wash, used on babies who have been 'attacked by sorcerers' (Burkill 1985-1997). Leaves of L. quandong [see **Santalum**] growing in Queensland [Australia] tested positive for alkaloids (Webb 1949). See also **Acacia** and **Duboisia**.

American mistletoes [Phoradendron spp.] may contain *tyramine* [0.027% (w/w) in leaf of a Phoradendron sp.] (Wheaton & Stewart 1970); P. flavescens has yielded *tyramine*, *phenethylamine* and *hordenine* (Smith 1977a); P. wattii yielded 0.1% *tyramine*; P. rubrum var. gracile yielded *GABA* (Durand et al. 1962). P. flavescens is carried as a charm by some followers of Voodoo (Rätsch 1992). P. vernicosum, 'xkeu', is used in Mexico to treat insanity, epilepsy, paralysis, and pain in childbirth (Heffern 1974).

AFRICAN OBSCURITIES

In some parts of Madagascar, Myrothamnus moschatus [Myosurandra moschata] (Myrothamnaceae) is known as 'riadiatra' or 'maharaoka'; it is a small herb growing on rocks. When grassland fires scorch the rock vegetation, locals collect the ready-dried herb to smoke as a euphoric inebriant, "believed to be exhilarating and, above all at the early stage, will provoke unrestrainable fits of laughter. However, those who smoke this plant habitually will soon become taciturn, cut themselves off from others and enter a state of growing autism. This may even lead to a schizophrenoid condition accompanied by abnormal irascibility which can gradually degenerate into fearful fits of violence" (Boiteau 1967; Samorini & Festi 1999).

Exomis microphyllum (Chenopodiaceae) is decocted to treat epilepsy in South Africa – a water decoction is said to be stupefying. The leaf contains saponins. Rhoicissus erythrodes (Vitaceae) also treats epilepsy, and the Masai decoct the root as a stimulant. The east African Gymnosporia spp. (Celastraceae) are used by the Karanga to treat epilepsy and madness (Watt 1967). Musanga cecropioides (Cecropiaceae) bark is used by the Fang of Guinea to treat schizophrenia (Akendengué 1992). 'Common rue' [Ruta graveolens; Rutaceae] has been used to treat epilepsy and hysteria in Africa, and is said to be narcotic, hypnotic and analgesic (Watt 1967). Iranian Zoroastrians may use it as a substitute for **Peganum** or **Ephedra** and pomegranate [see Punica granatum above] in 'haoma' beverages (Flattery & Schwartz 1989). However, it is also known to be toxic in large amounts (Chevallier 1996). In Germany, it has been known as a witch's herb ['hexenkraut'] (De Vries 1991). The source of the dye 'henna' [Lawsonia inermis; Lythraceae] is used in Ghana to treat hysteria and nervous disorders (Watt 1967). The powdered seed is also used in India, said to be a cerebral stimulant and cure for insanity; the flowers, bark and root bark have been used there as a soporific (Kirtikar & Basu 1980; Nadkarni 1976; Watt 1967). In Mexico, the plant is known as 'cuauxihuitl', and is used as a sedative; the crushed leaves and flowers are given in wine to treat hysteria (Diaz 1979; Heffern 1974). Moringa pterygosperma [M. oleifera] (Moringaceae) seed oil ['oil of Ben'] is used in central Africa to treat hysteria, and the root is used in India to treat this as well as epilepsy. The flowers, decocted in milk, are taken as an aphrodisiac. The plant contains alkaloids with an *ephedrine*-like action, and another that paralyses the CNS (Nadkarni 1976; Watt 1967). Morinda longiflora (Rubiaceae) ['brimstone tree'] is used in west tropical Africa to treat insanity and female sterility. M. lucida leaves are added to manioc wine in Ubangi, to flavour it and increase the potency. In Ghana, the tree has been used to ward off evil spirits (Burkill 1985-1997). Also in Ghana, leaves of Vernonia conferta (Compositae), 'flakwa', are added to palm wine for their aphrodisiac effects (Bremness 1994).

Anagallis arvensis (Primulaceae), 'scarlet pimpernell', was once used to treat mania and hydrophobia, and to 'dispel melancholy'; indeed, the generic name of this herb comes from a Greek word roughly meaning 'to laugh'. However, according to the 19th century botanist William Woolls, it has been reputed that "three drachms... are sufficient to kill a dog" (Cribb & Cribb 1981; Low 1990). In Africa, the herb of A. arvensis and bark of Andira inermis (Leguminosae) are said to be narcotic (Watt 1967). In Rhodesia, Anacampseros rhodesica (Portulacaceae) is used in making beer, and is thought to be narcotic; it was outlawed in Zimbabwe, and has been known as 'quilika' and 'tirika', names also given to Zantedeschia albomaculata (Araceae). In Zimbabwe, A. rhodesica is apparently used as a hallucinogen (De Smet 1998; Hargreaves 1999; Watt & Breyer-Brandwijk 1962). The roots of A. rhodesica, as well as those of A. alstoni, A. papyracea, and A. ustulata, have been used to brew the potent indigenous beer 'khadi' in S. Africa, as well as similar beverages in other regions [see also **Delosperma**, **Sceletium**] (Hargreaves 1999). In Tanganyika, Uvaria leptocladon (Annonaceae) roots are decocted to treat insanity and spirit-possession (Watt 1967). U. elliotiana has yielded 3,6-bis(γ,γ-dimethylallyl)indole (Husson 1985). In Congo, Heinsia crinita [H. pulchella] (Rubiaceae) ['bush apple'] root bark is added to palm wine as an aphrodisiac; in Tanganyika, the powdered root bark and leaf sap are taken to treat epilepsy (Burkill 1985-1997). Lichtensteinia interrupta (Umbelliferae) has been used in s. Africa to prepare snuffs, and the roots are used to prepare 'narcotic' beverages (De Smet 1998; Watt & Breyer-Brandwijk 1962). Tinospora bakis (Menispermaceae) roots have been used as a snuff ingredient by the Kusai of n. Ghana [see **Piper 1**]. It is also used to treat fevers and rheumatic pain, and has yielded palmatine (De Smet 1998). T. cordifolia ['guduchi'] is a Soma-substitute [see **Amanita**] in India, and is also used as a tonic. It is regarded as having the properties of 'amrita' (Müller-Ebeling et al. 2002).

In Gabon, Fagara altissima (Rutaceae) leaf is given with lemon juice to treat mental disease. In South Africa, F. capensis is used by Europeans to treat epilepsy, and its bark has analgesic properties. Bark of the w. African F. macrophylla is narcotic (Watt 1967). F. xanthoxyloides root bark is an ingredient of the n. Ghanan snuff mentioned above (De Smet 1998). In Brazil, the Jamamadi use a Fagara sp. known as 'balala' as an ingredient of their arrow-poison (Prance 1972). *Phenethylamine*-conjugates have been found in F. hyemalis [coryneine, tembamide] and F. rubescens [rubescamide]; candicine and *skimmianine* are also reported from the genus (Budavari et al. ed. 1989; Lundstrom 1989). In Liberia, Sabicea ferruginea (Rubiaceae) leaves are snuffed to give protection against malicious sorcery, and to empower the user to 'bewitch' their enemies; in Ivory Coast, the plant is snuffed for headache. In Ghana, S. calycina leaves are ground and rubbed on the legs of young children, to help them walk, and in Lagos, an infusion of the leaf is used as a memory tonic. The Yoruba invoke the plant in order to cause someone to lose their property. In Basutoland, Melolobium alpinum (Leguminosae) is given as a comforting sedative to the bereaved. The Southern Sotho rub the powdered ash of M. eriocalyx

[mixed with the gall from a black sheep] into brow scarifications to ward off evil spirits. The related M. candicans is suspected of causing stock poisonings. Ungernia minor (Amaryllidaceae) is said to be hallucinogenic, but this may be in confusion with **Boophane** disticha. *Hordenine* has been found in U. ferganica, U. trisphaera and U. victoris. Cardiospermum halicacabum (Sapindaceae), introduced to South Africa, treats nervous diseases. Children have developed 'epileptiform convulsions', probably from extreme excitation, after eating the seeds in quantity. The plant contains an alkaloid, quebrachitol. Carissa edulis (Apocynaceae) root is used in southern Africa as an aphrodisiac and stimulant. Also in s. Africa, the leaf of Hartogia capensis (Rutaceae) is chewed to prevent fatigue, quench thirst and suppress hunger (Burkill 1985-1997; Smith 1977a; Watt 1967; Watt & Breyer-Brandwijk 1962).

Mostuea gabonica and M. stimulans (Loganiaceae), called 'sata mbwanda' or 'sete mbwunde' in Gabon, are used there as an aphrodisiac and intoxicant. Grated chunks of the root are chewed either alone or with iboga [see **Tabernanthe**], to dispel sleep in long nights of drumming and dancing. It produces euphoria, and intoxication in higher doses, and has been compared to iboga in effect. M. stimulans roots yielded 0.15% alkaloids, the root bark 0.33%, and stem with leaves 0.06%. The alkaloids have not been identified, but two of those found in the root bark had similarities to gelsemine and sempervirine, alkaloids found in the 'yellow jessamine' [Gelsemium sempervirens; Loganiaceae] which has poisoned children who sucked on the flower nectar [in which the alkaloids are highly concentrated]. Symptoms of yellow jessamine poisoning include visual disturbances, dizziness, headache, muscular weakness, nausea, dry mouth, sweating and death in some cases (De Smet 1996, 1998; Foster & Caras 1994). As well as these alkaloids, G. sempervirens root contains *scopoletin* (Buckingham et al. ed. 1994). These symptoms, however, do not seem reminiscent of those accompanying Mostuea ingestion, and presumably, the chemistry may be more complex.

Picralima nitida (Apocynaceae) is used in central Africa for its psychoactive seeds, though with the bark and roots, they are also used to treat respiratory disorders and pneumonia (Arens et al. 1982). The plant is also used to poison fish, and the fruit has been used as a homicidal poison (De Smet 1998). Tissue cultures yielded the indole alkaloids pericine and pericalline, which showed opioid-receptor agonist properties. The plant has also yielded pseudoakuammigine, which is responsible for the cholinergic action of the drug, due to inhibition of butyrylcholinesterase (Arens et al. 1982). Sutherlandia frutescens (Leguminosae), 'cancer bush', is valued in southern Africa for its leaves and young stems, which are used as a panacea, treating internal tumours, inflammation, wounds, stomach ailments, colds, diabetes and other disorders. In Namaqualand, the seeds and leaves may be smoked as a substitute for 'dagga' [see **Cannabis**, **Leonotis**] (Van Wyk & Gericke 2000; Van Wyk et al. 1997). The Southern Sotho smoke Cineraria aspera (Compositae) ['mohodu-wa-pela'] leaves to relieve asthma and tuberculosis; although the herb is noted to be 'as intoxicating as **Cannabis** sativa (Watt & Breyer-Brandwijk 1962), it was not noted whether it is specifically smoked for this purpose also [I would presume it is!]. Aerial parts have yielded cinalyratyl angelate, sitosterol, and acetylenic compounds. In Zimbabwe, Heteropyxis dehniae (Myrtaceae) leaves are sometimes smoked and chewed "for the arousal of spirits". Members of the genus contain essential oils. Also in Zimbabwe, roots of Cynodon dactylon (Gramineae) [in Nepal, known as 'dubhotar', it is considered a form of 'amrita' (Müller-Ebeling et al. 2002)], Diplolophium zambesiacum (Umbelliferae) and/or Hyparrhenia filipendula (Gramineae) are consumed to 'arouse spirits'. Zulu healers sometimes consume roots of plants such as Canthium ciliatum (Rubiaceae), Hippobromus pauciflorus (Sapindaceae) or Turraea floribunda (Meliaceae) before 'divining dances', to induce trance and produce vomiting. The Zulu use roots and stems of Brachylaena discolor (Compositae) to "communicate with the ancestors"; aerial parts have yielded onopordopicrin and other compounds (De Smet 1998).

Masai warriors are known to ingest [amongst other drugs – see elsewhere in this chapter, also **Acacia**] Agauria salicifolia (Ericaceae) ['en gomani'], Euclea schimperi [E. kellau; 'ol gireni'] (Ebenaceae), bulbs of a Haemanthus sp. (Amaryllidaceae) ['ol gitende'; H. katharinae leaf has yielded traces of *tyramine*, N-methyltyramine and synephrine], Maesa lanceolata (Myrsinaceae) ['ol odoa', 'ol onorua'] fruits and Olinia vokensii (Oliniaceae) ['ol gireni'], as stimulant-excitants. For this purpose they are often eaten with meat, enriched with extracts from the same plants [see *Methods of Ingestion*]. The Masai have also been recorded as preparing a similar intoxicating beverage with honey, water, and roots of either an Aloe sp. (Liliaceae) ['steppe Aloe'; see below] or Kigelia aethiopica (Bignoniaceae) (Lehmann & Mihalyi 1982; Wheaton & Stewart 1970). In Tanzania, K. aethiopica fruit is also added to beer to strengthen it, though the addition can cause strong headaches. In Kenya, K. africana fruit is added to beer (De Smet 1998; Watt & Breyer-Brandwijk 1962). Regarding Euclea spp., E. natalensis ['Natal guarri'] is reportedly smoked as a hypnotic (Van Wyk & Gericke 2000; Van Wyk et al. 1997), and E. divinorum ['magic guarri'] has been administered as an ordeal poison (pers. comms.).

In Tanzania, Lachnopylis platyphylla (Loganiaceae) leaf is added to sugar-cane beer; it is believed to enhance fermentation, and/or increase the intoxicating powers of the beer (Watt & Breyer-Brandwijk 1962). Roots of Millettia usaramensis (Leguminosae) are soaked in palm wine [see *Methods of Ingestion*] to give it aphrodisiac properties. Root of the related M. sanagana is sometimes used as a homicidal poison. Members of the genus have been found to contain rotenone [see **Lonchocarpus**]. Pericopsis laxiflora [Afrormosia laxiflora] (Leguminosae) roots are known to be slightly intoxicating, and for this reason are sometimes added to palm wine. Unspecified parts of the plant have been used to prepare arrow poison, and as an ingredient of composite stimulant drugs. N-methyl-*cytisine* has been tentatively identified as one of the alkaloids present in the stem and root barks (De Smet 1998).

In s. Africa, the Zulu, Swazi, Tsonga, Venda and Sotho use the ripe fruits of Sclerocarya caffra [S. birrea ssp. caffra] (Anacardiaceae) ['marula', 'umganu'], S. birrea ['marula'] and/or S. schweinfurthii to brew beers known as 'ukanya' which are particularly intoxicating (De Smet 1998; Emboden 1979a). S. caffra has been suggested to have been the 'kanna' referred to by early explorers amongst the Hottentot, rather than members of the genus **Sceletium** (Emboden 1979a). The root is consumed in Zimbabwe to 'arouse spirits' (De Smet 1998).

The Basuto are said to use a white-flowered plant believed to be a Myosotis sp. (Boraginaceae) ['forget-me-not'] in the initiation of their shamans. It is known to them as 'sethuthu', and as 'lephukhuphukhu' to the Zulus. It is said to have "great powers of acting on the brain and developing mental faculties, especially the memory", aiding the shaman in learning about medicinal plants, and other functions and abilities required of them. This herb is also the main ingredient of a composite medicine given, by the shaman, to one who is suffering from hysteria. Other ingredients are claimed to include the roots of Agapanthus umbellatus (Amaryllidaceae) ['leta la phofu'], **Galium** witbergense ['seharane'], a **Polygala** sp. ['bolao ba maqekha'], and a Polygonum sp. (Polygonaceae) ['morara o moholo'; see below]. The preparation is supposed to cause the patient to 'dream' of medicinal plants that s/he must collect the next day. Sethuthu is also reportedly the main ingredient of an ointment used to anoint a new bride before she consummates her marriage (Laydevant 1932). A Peruvian Myosotis sp. known as 'buena esperanza' is taken as a water infusion to treat debility (De Feo 2003).

Several African plants of the Malpighiaceae [eg. see **Banisteriopsis**] have some interesting uses recorded. Acridocarpus natalitius is used by the Tsonga of Mozambique, as a "war medicine and in the purification rites after death". Tsonga shamans use the plant to protect against malevolent sorcery from competitors. The Xhosa use sticks from the plant to protect against sorcerers and lightning. A. plagiopterus twigs are used as an aphrodisiac in the Lower Casamance; stems and leaves are macerated to prepare a body-wash which acts as a 'strengthening tonic'. The root is credited with 'magical properties' in Senegal and Guinea, and has been used to 'exorcise devils'. A. spectabilis root is chewed as a cola nut substitute [see **Cola**] in parts of Gambia and Senegal. Tenda singers chew it raw to 'strengthen the voice for singing'. Sphedamnocarpus pruriens is used by the Chopi with **Securidaca** longepedunculata to treat possession by evil spirits (Burkill 1985-1997; Watt & Breyer-Brandwijk 1962).

Numerous Aizoaceous succulents [besides **Delosperma**, **Nananthus**, **Sceletium** and others discussed under **Sceletium**] from southern Africa seem to have psychotropic potential. Unidentified species from the genus Conophytum have been reported to be 'narcotic' (Watt 1967; Watt & Breyer-Brandwijk 1962). This, and several other Aizoaceous genera, have species commonly known as 'living rocks', due to their similarity in appearance to small rocks or pebbles protruding from the ground. Pleiospilos bolusii, which has a 'living-rock'-like appearance, has recently been bioassayed, and reported to be psychoactive, most likely containing *mesembrine*-type alkaloids (friendly pers. comm.). Gibbaeum dispar is another living rock which has been found to be psychoactive when snuffed or smoked [prepared as for **Sceletium**] (Van Wyk & Gericke 2000; Van Wyk et al. 1997). Many other Aizoaceous genera also fit the 'living-rock' appearance – such as members of the genera Argyroderma, Dinteranthus, Lithops, Ophthalmophyllum and Titanopsis.

The related Psilocaulon absimile ['asbos', 'loogbos'] has yielded 4.5% piperidine [see **Piper 1**] (Henry 1939), an alkaloid, psilocaulin [which might be piperidine – Ed.], 8.66% oxalic acid [see **Sceletium**], 11.02% malic acid and 0.069% tartaric acid. The plant has caused stock poisonings, as well as causing death in rabbits [from a dose of 100g fresh plant], although rabbits did not suffer any negative effects when given 50g a day for 2 days. However, 50g of a wilted plant [an unidentified Psilocaulon sp.] was sufficient to kill rabbits in another experiment, although 120g of fresh plant cultivated from this population later caused no toxicity. This unidentified species is sometimes used in dipping tobacco [see **Nicotiana**]. Toxicity is believed to be due to the oxalic acid and alkaloid content. Piperidine is considered toxic, and has activities comparable to those of *nicotine*, *coniine* and *lobeline* (Steyn 1934; Watt & Breyer-

Brandwijk 1962).

Aloe spp. (Liliaceae), succulents unrelated to the above plants, are best known for their famed representative A. vera [A. barbadensis], the sap of which is widely applied to wounds or burns, and used as a laxative (Chevallier 1996). In the Kalahari, A. ferox ['umhlaba'] has been portrayed in Bushman rock paintings; its flower nectar is reputedly narcotic. Apparently, bees raised on A. greatheadii var. davyana ['kgophane'] flowers become "unusually vicious". The Kgatla use the plant in rain magic. Leaf sap from A. globuligemma ['gava kava'] has been used in arrow poisons, and contains coniceine [see **Conium**]. Tea made from the root and leaf of A. arborescens is sometimes drunk to relieve stress, hypertension and arthritis. Dried, powdered A. marlothii leaves ['mokgopha'] are sometimes mixed with psychotropic snuffs (Van Wyk & Gericke 2000; Van Wyk et al. 1997) such as those prepared from tobacco [**Nicotiana**]. Sometimes it is burnt to an alkaline ash for this purpose, and sometimes such Aloe spp. ash is snuffed by itself, which may be common in parts of the Transvaal. In Basutoland, A. aristata and A. saponaria var. ficksburgensis are similarly snuffed with tobacco, as is the unrelated Cussonia spicata (Araliaceae) in Transvaal (Watt & Breyer-Brandwijk 1962).

Recently, Silene capensis (Caryophyllaceae) was reported to be the major shamanic plant of Xhosa diviners ['amagqirha'] in S. Africa. The roots, known as 'undlela ziimhlophe' ['white ways' or 'white paths'], are powdered and drunk with water on an empty stomach, for divination. The effects manifest during sleep, as lucid prophetic dreaming with content rich in significance. There are usually no perceived effects in the waking state, though one apprentice diviner noted wandering thoughts shortly after ingestion; 20 mins after ingestion, he perceived "wavy lines of light in the air", which reminded him of "the reflections of light on the surface of moving water". It is fitting to note that amongst the Xhosa, divination is associated with going under water. A dose for divination may be c.200-250mg of powdered root; in larger doses, it is used as an emetic. Most interestingly, the plant is reputed to have no mental effects in people who are not predisposed to being diviners. Chemistry of S. capensis is unknown, but due to the foam created when the powdered roots are mixed with water, it probably contains saponins. Dianthus albens (Caryophyllaceae) ['impendulo', 'ubulawu'] might have similar properties (Hirst 2001), but this was not made clear.

In s. Nigeria, numerous ferns and fern-allies are used in manners indicating psychotropic and magical properties. Dryopteris filix-mas (Dryopteridaceae) ['common wild fern', 'erinji', 'ihi'] leaves are infused and taken as an aphrodisiac (Nwosu 2002). In Nepal, tips of D. filis-mas ['uniw pati'] and other D. spp. have been used in ritual incense (Müller-Ebeling et al. 2002). The 'royal fern' or 'eboshi', Osmunda regalis (Osmundaceae), is consumed in the form of an extract of the whole plant, to treat psychosis and 'moon-madness', and "chase away evil spirits". The 'savannah fern' ['ami ogwu', 'usele'], Gleichenia linearis (Gleichenaceae), is similarly prepared and consumed to relieve convulsions in children, followed by a cold bath and occasionally incantations from the local healer to drive away illness-causing evil spirits. Nephrolepsis cordifolia (Nephrolepidaceae) ['erect swordfern', 'nma ozo'] fronds are infused and taken by the elderly to treat amnesia. Equisetum diffusum (Equisetaceae) ['branched horsetail', 'aziza', 'eru'] roots are decocted and taken to treat psychosis (Nwosu 2002). In central America, the Lacandon Maya use a tea of fresh E. myriochaetum as a male aphrodisiac (Rätsch 1990). See also Cyathea spp., Cheilanthes spp. and Hypodematium spp. below.

OBSCURITIES FROM PAPUA NEW GUINEA, including SOME NOTES ON GINGER and SCENT GLANDS

It is well worth mentioning that the common spice ginger [Zingiber officinale; Zingiberaceae] is known to produce psychotropic effects when consumed in large amounts. Leaves and rhizomes of ginger are chewed by the Nkopo of Papua New Guinea [PNG] as a dance stimulant. The Bimin-Kuskusmin use special 'ritual' strains of different ginger types in the first 3 stages of their 12-stage initiation procedures. In stage 1, **Alpinia** sp. ['khraaniik'; see **Kaempferia, Alpinia**] and a Hornstedtia sp. (Zingiberaceae) ['khraanuuk'] are used; stage 2 uses Z. officinale ['muukhraar']; stage 3 uses Z. officinale ['naasiir'] and what is probably Z. zerumbet ['naasuur']. After successively extended periods of fasting and sleep deprivation, ginger leaves [young shoots from near the rhizome] are crushed and placed in the nostrils, and peeled rhizomes are eaten. The initiate is exposed to the heat of a fire during this stage. As well as the expected burning sensations in the gut, the ginger taken under these circumstances produces blurred vision, visual and auditory hallucinations, disorientation, dissociation, trembling, dizziness, immobility, nausea and dehydration. However, it is to be expected that the effects of the ingested ginger are greatly exacerbated by the conditions under which it is taken, and the other plants involved – ie. 'nettles' (Urticaceae) [Fleuryia sp. – 'abioomkhyr'; Laportea spp. – 'ganganyiin' and 'gukhaabiom'; see also **Urtica**] being rubbed on the body, inhalation of vapours from crushed leaves [**Evodia** sp. – 'saakop'; Elatostema sp. (Urticaceae) – 'waar'; Achyranthes sp. (Amaranthaceae) – 'suung'] and the consumption of **Pandanus**, **Dodonaea**, Eugenia sp. [see **Syzygium**], the fern Cyathea sp. (Pteridophyta) ['faam'], 'spiderwort' leaf Commelina diffusa (Commelinaceae) ['saamkop'] [these two aiding in alignment of personal spirit-aspects; some Commelina spp. contain β-carbolines – see below] and nuts of Lithocarpus spp. (Fagaceae) ['aramaar', 'baang' and 'kong' – produces dizziness, promotes 'ritual insight'], as well as other plants for which there is no evidence of psychoactivity (Poole 1987; Schmid 1991; Weil 1969). A Laportea sp. (Urticaceae) ['salak'] is also used by the Komba of Morobe to become 'magically powerful', and the Minyamin of Yominbip flagellate themselves with a Laportea sp. as a stimulant for long journeys. The Wopkaimin use a Laportea sp. ['bimgalgol'] in ritual medicine (Thomas 1999, 2001a). See also the related Dendrocnide spp. above.

Ginger [Z. officinale] contains over 500 chemical constituents, some of which have psychoactive potential. Ginger is known to be a stimulant, and is also anti-inflammatory, antibacterial, anthelmintic, antifungal, antiviral, antioxidant, lowers cholesterol, regulates hormones and body temperature, counteracts nausea, and has many other recognised medicinal actions. The ancient Chinese claimed long-term use would "put a person in contact with the spiritual effulgences"; the Koran referred to it as a beverage of the holiest heavenly spirits; and in Persia it was recognised as having head-clearing properties. It is also much regarded in Asia as an aphrodisiac. It is very important in magical and ritual practices throughout Asia and the south Pacific (Perry & Metzger 1980; Rätsch 1992; Schulick 1996), and makes a great beer (Buhner 1998; pers. obs.)! The Kirati of Nepal regard ginger ['yari', 'deshukpa'] as very important shamanically, playing a part in many rituals. A piece may be eaten to aid entry into trance, and it is said to "bring clarity to the spirit" (Müller-Ebeling et al. 2002). In Siberut, Indonesia, shamans drip ginger juice into the eys of their apprentices, so that they may 'see' (Rätsch 1998). In Amazonia, Z. officinale ['ajej'] is consumed by Shuar, Achuar and Aguaruna shamans as a 'hallucinogen', to 'gain power'. The Cariña mix it with tobacco and apply it to the eyes of apprentice shamans – this apparently allows them to 'see spirits' (Bennett 1992).

Going back to our friends the Bimin-Kuskusmin, we find that their extended initiation rituals are a very complex process, involving ingestion of many different combinations of different substances, and an abundance of taboos and special procedures regarding the use of the major herbs which the rituals revolve around – that is ginger [stages 1-3], **Nicotiana** [stages 4-9] and mushrooms [see **Boletus** and **Psilocybe**; stages 10-12 – not compulsory, but required to be a fully initiated elder]. They are conducted at dawn, dusk, and night, respectively, and gradually increase the intensity of the experience at each stage. Methods used include mainly increasing degrees of fasting, sleep-deprivation, and exposure to harsh elements [proximity to fire, 1-3; rain and cold wind, 4-9; rain, cold wind, lightning and thunder (with drumming in rhythm with the latter), 10-12] (Poole 1987). Full details are too complex to enter into further, unfortunately.

Casuarina equisitifolia (Casuarinaceae) is used in Enga, PNG – the inner bark is scraped, and its juice used as a sedative for aggressive or mentally disturbed people. It has been used for a similar purpose in Malaysia. Leaves of 'pehea' or 'aseki' [Fagraea bodenii; Gentianaceae] are chewed by some warriors as a stimulant before battle (Woodley ed. 1991). Throughout Polynesia, Fagraea spp. are associated with "gods and the afterlife". Incidentally, F. berteroana flower essential oil is said to "restore mental clarity and purposefulness", reduce drug cravings, especially for **Cannabis**, and reduce sexual urges. In Cambodia, F. fragrans bark is infused and drunk as a tea by the elderly to prolong life; freshly cut bark of this species is reported to give contact dermatitis. The plant contains the iridoid gentianine. In Sarawak, leaves and bark of F. racemosa are decocted as a tonic; in Sabah, as 'todopon puok', roots are used as an analgesic and local aneasthetic. The roots contain lignins [(+)-pinoresinol, (+)-lariciresinol, (+)-isolariciresinol] and phenols [syringaldehyde, 7,8-dihydro-7-oxyconiferyl alcohol] which share these activities in animals (Motley 2004).

Ginger, Endospermum formicarum (Leguminosae) and a Homalanthus sp. (Euphorbiaceae) are used to 'make young warriors fierce' (Paijmans ed. 1976). In Mt Hagen and the Jimi Valley of the Western Highlands, Endospermum maluccanum has been used for the same purpose. In the Chimbu area, a Palmeria sp. (Monimiaceae) has also been used as a battle stimulant (Thomas 1999). In the Bismarck Archipelago, fruit of Ptychococcus paradoxus (Arecaceae) is chewed as a betel nut substitute [see **Areca**]. The Adzera chew fruits of a Costus sp. (Zingiberaceae) ['jangun', 'jangun fagata'] as a betel nut substitute (Thomas 2001a). Incidentally, in Congo the stem of a plant known as 'mukhuisa' [also spelled 'munkwiza', 'nkwisa', 'nkuisa'], which may be a Costus sp. such as C. lucanusianus, is chewed by medicine men and the juice spat at people gathered around; all present then drink a beverage made from the plant. The purpose of this ritual is to drive out evil spirits (De Smet 1998). In Nepal, C. speciosus ['kusha'] may be used as ritual incense by shamans if none of the preferred substances are available; however, it is not thought to have any psychotropic effect (Müller-

Ebeling et al. 2002). The Gimi of the Eastern Highlands ritually smoke an Amaracarpus sp. (Rubiaceae) with tobacco, to enter trance. In the Kema Valley, a Beaumontia sp. (Apocynaceae) is sometimes smoked as a tobacco substitute. The Baining of New Britain chew Cryptocarya aromatica (Lauraceae) bark with lime and leaf of a **Piper** sp., as a betel nut substitute; in n.e. Irian Jaya, bark of C. aromatica is chewed 'to contact supernatural beings'. The Baining also consume tubers of an Alocasia sp. ['wild taro'] and/or Colocasia esculenta ['taro'] (both Araceae) during their dancing ceremonies, whilst chewing betel nuts, and having been chewing betel nuts for the last 5 days. Laportea sp. leaves [see above] are also ingested to counteract the toxicity of these plants. In East Sepik, an Alocasia sp. is used by the Komba for 'malevolent sorcery'. On Mabuiag, w. Torres Strait, root and leaves of a Capparis sp. (Capparaceae) ['kara'] are eaten by shamans 'to become wild'; the unripe fruits are eaten by novices during their initiations (Thomas 2001a). In some parts of Africa, C. tomentosa root is used as a homicidal poison; the plant contains alkaloids and saponins (De Smet 1998). At Mt. Hagen, Pteridium aquilinum (Polypodiaceae) ['pugl'] juice is used as a stimulant; Drymaria cordata (Caryophyllaceae) ['romp-romp'] is eaten in small amounts either raw with alkaline ashes, or cooked with a vegetable, as a stimulant. Locals also obtain bark of an unidentified plant, known as 'tipo', from other tribes. Its use is still mysterious, but drinking a decoction is said to cause the consumer to lose their wits (Stopp 1963).

Inhabitants of Nokopo, in the Madang & Morobe provinces of PNG, use a number of obscure substances for ritual and inebriation. A number of plants are used as narcotic intoxicants – including 'muk muk' [Dendrobium spp.; Orchidaceae] leaves, 'kuya' [Garcinia sp.; Guttiferae] bark [sometimes chewed as an intoxicant with betel nut – see **Areca**; the African G. kola is known as 'bitter kola' – see **Cola**], 'dsopang' [Heterospathe sp.; Palmaceae] fruits, 'marapinpin' [Nicolaia elatior; Zingiberaceae] fruits and 'kiyang kiyang' [Viola gibbilimbum; Violaceae] leaves. Plants, and even animal parts, are also chewed as stimulants for long sessions of singing, chanting and dancing at night, such as 'deeng karang mondsin' [Dendrobium sp.] shoots, 'waumung' [Pittosporum sp.; Pittosporaceae] root cortex [the scent of the crushed root of P. venulosum is said to be aphrodisiac by Queensland natives (Lassak & McCarthy 1990), and bark of P. floribundum is considered narcotic in India, when taken in small and safe doses (Nadkarni 1976)], 'mokei' [possibly a Pterostylis sp.; Orchidaceae] leaves, 'nyingwaol dsaap' [an orchid] leaves, 'keenem katam' or 'upmung kwik' [a fern] fronds, and herbage of 'bumumak mondsin' and 'temiyat kwik kwak' [members of the Labiatae]. 'Katam', the anus glands of the 'dusky wallaby' [Thylogale brunii], 'forest wallaby' [Thylogale sp.; 'pademelon'], 'silky cuscus' [Phalanger sericeus], 'spotted cuscus' [Spilocuscus sp.] and 'eastern ringtail' [Pseudochirulus forbesi] marsupials are sometimes combined with these plants. Other plants are crushed and rubbed on the body by men before sleeping, in order to meet bush spirits ['sinduk'] who teach them new songs and rhythms, which are valued for the vital energy they carry as gifts from the forest. A 'club moss' [**Lycopodium** squarrosum] is mentioned under its own entry – also used are 'dsimok' [possibly a Dendrobium sp.] and 'suva yut' [possibly a Epiblastus sp.; Orchidaceae] (Flannery 1995 [for marsupial identification]; Schmid 1991).

Regarding Dendrobium spp., many have interesting uses where they occur, so we will temporarily diverge to discuss them. Stems, leaves and pods of D. hancockii promote a feeling of wellbeing and psychic sensitivity when taken regularly (Trout pers. comm.). In s.e. Asia, D. pulchellum flowers are fed to hunting dogs to improve their skill, and D. ceraia has been used to treat phobias, epilepsy, nervous complaints, rheumatic pain and debility. D. crumenatum is also used for nervous or mental problems, and the bulb sap used to treat earache. In Vietnam, D. ceraia is decocted to make a refreshing tonic beverage. In Seram, Indonesia, men wore D. acinaciforme in their armbands for courage during raids. In Taiwan, D. moniliforme is taken "to fortify the person" and their kidneys. In TCM, D. nobile and sometimes other species have been used as 'shihhu', as a strengthening longevity tonic, aphrodisiac, analgesic with many other properties; the stems are used in a dose of 5-10g [dried]. The alkaloid dendrobine is the primary active component. D. devonianum nectar has a narcotic effect on visiting insects, as does nectar from the orchids Catasetum spp., Cycnoches spp., Diuris pedunculata, Gongora spp., Pterostylis recurva, P. sargentii and Stanhopea spp.; S. tigrina is used in Mexico to relieve weakness and sunstroke (Lawler 1984). Of these, alkaloids have been detected in Catasetum spp., Cycnoches spp., Gongora spp. and Stanhopea spp. (Lüning 1967). The orchids Arethusa bulbosa ['dragon's mouth'], Cymbidium devonianum ['Devon's Cymbidium'; alkaloids found in genus] and Goodyera pubescens ['rattlesnake orchid'; alkaloids found in genus] also contain 'narcotic' compounds (Lüning 1967; Rätsch 1992). The latter has been used as an analgesic by the Cherokee (Hamel & Chiltoskey 1975), as has G. menziesii by other tribes (Lawler 1984).

To diverge again, in relation to the use of anus glands just mentioned, many animal secretions have aphrodisiac and/or psychotropic effects. The scent gland secretions of the Canadian beaver, Castor fiber, have been used as an aphrodisiac (Rätsch 1990); they have been found to contain a number of alkaloids, some of which are related to compounds found in **Nymphaea** – 0.12% castoramine, 0.024% isocastoramine, 0.008% deoxynupharidine, and lesser amounts of other compounds (Maurer & Ohloff 1976). In India, the dried secretions [which smell of cat urine; the product is presumably imported] are used in doses of 1-2g as a nervous stimulant and antispasmodic to treat hysteria, epilepsy and asthma. The secretion also acts as a uterotonic and emmenagogue. Also in India, secretions from the pouch between the anus and genitals of the civet cat Viverra civetta ['gandha-marjara', 'zebad'] are taken as a stimulant, aphrodisiac, nervine and antispasmodic, as well as being used as a perfume ingredient. The secretion [the 'civet'] contains zibetone, a compound with a similar structure to muscone, a major active principle in 'musk'. Musk, an aromatic testicular secretion from certain Asian musk deer [such as Moschus moschiferus or M. sifanicus] released when rutting, is used in Ayurveda as an exhilarating nerve stimulant, respiratory stimulant, antispasmodic, cardiac tonic and aphrodisiac; with prolonged exposure or high doses, it acts as a soporific narcotic. In China, it has long been claimed that musk could "increase the intelligence quotient of children". In TCM, as 'she xiang', it is taken in doses of up to 200-375mg as a stimulant and cardiotonic, and is generally used to treat stroke, shock or convulsions. In larger doses, however, it acts as a CNS depressant. Side effects may include dizziness, nausea and vomiting. It can stimulate the production of male sex hormones, and promote contraction of the uterus (Huang 1993; Landerer 1883; Nadkarni 1976). Incidentally, the velvet antlers from the deer Cervus elaphus have been shown experimentally to inhibit *morphine* tolerance and dependence, when extracts were administered repeatedly to mice (Kima et al. 1999). 'Ambergris' is another famed aphrodisiac animal secretion also used in perfumery, and originates from the intestines of the 'sperm whale' Pyseter macrocephalus; the fact that it is usually found floating in the sea fortunately means the whales are [usually] not killed to obtain it. The genitalia, horns and other body parts of a great variety of other mammals have been thought to be aphrodisiacs, and some others not listed here are mentioned by Rätsch (1990).

The boar pheromone 5α-androstenol, also secreted by male humans and found in urine of female humans, has been found in 'black truffles' [Tuber melanosporum] and 'white truffles' [T. magnatum], and appears to have an aphrodisiac effect on humans (Claus et al. 1981). It was thought to be the chemical which attracted sows to underground truffles, but this action appears to be due entirely to the dimethylsulphide produced by the fungi (Talou et al. 1990). Sows are, however, 'turned on' by the boar pheromone 5α-androstenone (Claus & Hoppen 1979). These truffles have a reputation as human aphrodisiacs, possibly due to the aroma of 5α-androstenol, though it is unclear whether they are effective (Schaecter 1997).

The infamous scent of skunk [Mephitis spp. and Spilogale spp.] has been reported to act as a strong stupefacient. One boy who inadvertently inhaled 'skunk perfume' on the suggestion of his friends suffered "total unconsciousness, muscular relaxation, a temperature of 94°[F] and pulse of 65, together with cool extremities" (Conway 1881).

LATIN AMERICAN OBSCURITIES

There exist many little-known plants of Central and South America which may have psychoactive properties, of which the following is a selection, including discussion of related species from elsewhere in the world. No doubt many more remain to be discovered by us.

Abuta grandifolia (Menispermaceae), 'abuta caimitillo' or 'sanango' is sometimes added to ayahuasca [see **Banisteriopsis**] (McKenna et al. 1995); it may be taken by itself as a plant teacher (Luna 1984). Root tea is used in Ecuador to make children strong, and relieve their nervousness and/or colic. One cup of such a brew is considered strong enough to produce strengthening effects lasting for a year. The plant is used by various Amazonian tribes in preparing 'curare' arrow poisons. The barks of A. grisebachii, A. imene, A. obovata, A. rufescens, A. sellowana and A. splendida have also been used in preparing curares or other arrow poisons for hunting, as have many other plants from the Menispermaceae – such as members of the genera Anomospermum, Chondrodendron [see below], Cissampelos [see Cocculus below], Curarea, Orthomene [see below], Sciadotenia and Telitoxicum [see also **Strychnos**] (Schultes & Raffauf 1990). A. grandifolia contains oxo-aporphines, including palmatine; bark tested positive for alkaloids (McKenna et al. 1995).

'Achunisanango' [unidentified] is used in Peru as a potent male sexual tonic; the root is taken in alcohol with honey (Bear & Vasquez 2000).

Anemopaegma mirandum [A. arvense] (Bignoniaceae), 'catuaba' or 'tree of togetherness', is used for its root by the Tupi of S. America as a CNS-stimulant, relaxant, and aphrodisiac nerve tonic (Baill pers. comm.; Mors & Rizzini 1966; Usher 1974).

Anthurium oxycarpum (Araceae), 'yeurycumajé', is used in Amazonian Peru and Brazil to flavour tobacco [see **Nicotiana**], as it is aromatic when shade-dried; it may also be snuffed alone as an aphrodisiac (Plowman 1969). The dried, powdered leaves are said to be made into a 'hallucinogenic concoction' by the Yumbo and the Quichua of Ecuador (Croat

1994) but this is referenced to Schultes & Raffauf (1990), who only identified the plant so used by its herbarium number, as A. sp. Bv 2936.

Aristolochia medicinalis (Aristolochiaceae) is used by the Kubeo for its root, which is made into a tea to treat epilepsy. If taken in excess, it can cause 'permanent' mental derangement and sometimes muscular paralysis. The genus contains aporphine and berberine-type alkaloids, as well as nitrophenanthrene derivatives and essential oil (Schultes 1993; Schultes & Raffauf 1990). Leaves of species growing in Queensland [Australia], A. deltantha, A. elegans, A. praevenosa and an unidentified species, tested strongly positive for the presence of alkaloids (Webb 1949). In India, A. indica is reputed to be a potent aphrodisiac (Islam et al. 1991).

Astrophytum myriostigma ['peyote cimarrón', 'birrete de obispo', 'mitra'], A. asterias ['peyote'] and A. capricorne ['peyote'] (Cactaceae) are known as kinds of peyote in n. Mexico, though this is thought to be due only to a superficial resemblance to true peyote [see **Lophophora**]; they have been shown to contain "traces of toxic alkaloids" (Bravo 1937; Schultes 1937a, 1937b). However, the reference by Schultes (1937b) to A. capricorne being a 'peyote' may be in error, as he referred this to Britton & Rose, who did not mention any such information, except for A. asterias (Britton & Rose 1963 [note – orig. publ. 1922]). One person claimed to have eaten small [5cm diam. or less] nursery-bought specimens of A. myriostigma on numerous occasions, with 1½-5 specimens required for noticable psychotropic effects; however, the same person reported eating a larger, much more fibrous specimen [c.7.5cm diam.] which "sat very heavily" in his or her stomach and produced no CNS effects (R.D. 2002). Some cactus growers in s. California have reportedly observed jackrabbits nibbling on the ribs of A. myriostigma becoming noticeably intoxicated, as well as returning for more when the effects appeared to have worn off (Anon. 1998)!

Bernoullia flammea (Bombaceae) ['amapola blanca'] seeds are smoked in Guatemala near the Mayan ruins of Tikal , as an 'opium-like' narcotic [see **Papaver**] (Rätsch 1998).

Bletia campanulata (Orchidaceae) has been known as 'peyote cimarrón' (Schultes 1937b) and 'peyote' (Smith 2000) [see **Lophophora**], though it is not known whether this orchid has medicinal or psychotropic uses. It contains an alkaloid (Lüning 1967). B. hyacinthina has been used medicinally in China, Mongolia, Tibet and Japan as a lung tonic and blood purifier, though it is also "said to produce a state of euphoria" (Lawler 1984).

Browningia spp. (Cactaceae) are large, columnar cacti from S. America, many being quite similar to some **Trichocereus** in appearance. The 'El Candelabro' marking amongst the famous 'Nazca Lines' [made by the Peruvian Nazca culture, c.300-800AD] has been proposed to represent B. candelaris, a prominent species of the area. Although its significance is not known, it is suspected that the cactus represented was known to the Nazca as a visionary plant (Ostolaza 1987, 1997). The only analysis of the genus for alkaloids I'm aware of detected no *mescaline* in B. candelaris or B. microsperma, but did not look for other alkaloids (Cjuno et al. 2007). The stunningly beautiful B. hertlingianus [Azureocereus hertlingianus, A. nobilis] is common in horticulture, though its slow growth and unwillingness to take from cuttings has probably hindered human bioassay. It is also unfortunately quite frost sensitive, at least when young (pers. obs.).

Buddleia humboldtiana (Loganiaceae), as 'tepozan', is used in Mexico as a hypnotic, anaesthetic, diuretic and anodyne; it is a CNS-depressant (Jiu 1966). B. americana has been reported from Mexico, Guatemala and Costa Rica to have roots with hypnotic and sedative properties. In Brazil, B. quinquenaria has been used in infusion as a nerve sedative. In n. India, roots of the related B. asiatica have been used to make a 'fermented liquor'; in some parts of the Philippines, the smoke of the plant is used to soothe irritated babies. In China, leaves of B. curviflora have been used to stupefy fish (Houghton 1984). In Nepal, B. asiatica ['bhimsen pate'] and B. paniculata ['narayan pati'] leaves are used in ritual incense (Müller-Ebeling et al. 2002). Butterflies have also been observed in an intoxicated state from feeding on flowers of a Buddleia sp. growing ornamentally in England (Smullen 1989).

Bursera bipinnata (Burseraceae) has been proposed to have been the tree known to the Aztecs as 'teuvetli', the resins from which were applied to wounds on sacrificial victims to induce a semi-trance (Case et al. 2003; Emboden 1979a). However, there is no actual evidence to support this tentative identification, apart from the copious resin-production of the plant. B. bipinnata has been used as an additive to 'pulqué' [see *Methods of Ingestion*] (Rätsch 1998). The oleo-resin contains epi-lupeol and α-amyrin. B. graveolens, from Colombia and Peru, is used for its leaves, which are decocted to relieve muscular fatigue. The oleo-resins from B. gummifera and B. tomentosa, which are used to treat tumours, contain *elemicin* (Pernet 1972). In Sonora, Seri shamans hold bundles of B. microphylla twigs in their curing ceremonies; they also use fetishes carved from B. hindsiana wood, which may be hired out to others for domestic use. The Seri also drink a tea of B. laxiflora bark [the dark portion] to relieve pain from scorpion stings or 'black widow' spider bites [see below] (Felger & Moser 1974). Seri shamans drink a tea of B. microphylla branches throughout their 4-day vision quests [in which fasting is observed] (Felger & Moser 1985). B. copallifera and many other members of the genus are used as sources of 'copal' incense resin in Mexico (Case et al. 2003).

Cacalia cordifolia (Compositae) is known as 'peyote' by the Tarahumara [see **Lophophora**], and is sold in markets in Jalisco [Mexico] as an aphrodisiac and sterility cure (Schultes 1937a, 1937b). C. decomposita has been reported to be used to stun fish in n. Mexico (Pennington 1958).

Carludovica palmata (Cyclanthaceae) ['bonbonaje'] root is said to be cooked and eaten by some shamans in the Peruvian Amazon as part of a strict diet – the shaman is said to 'become powerful and filled with the spirit of the bonbonaje plant', dreaming 'sacred and spiritual things'; however, the truth of this information is uncertain (Montgomery 1997a, 1999). Fibres from this tree make the famous Panama hats (Usher 1974). C. divergens ['tamshi'] bark is used as an ayahuasca additive [see **Banisteriopsis**] (Trout ed. 1998); it is used medicinally to treat baldness and cramps. The tree is said to grow from the dead body of a large, stinging ant ['isula']; the spirit of the tree is able to transform into this ant (Luna & Amaringo 1991).

Cedrelinga castenaeformis (Leguminosae) is known as 'paricà' in parts of Brazil [see **Anadenanthera**, **Virola**] (Schultes 1955a), and as 'huayracaspi' in Peru. It may be taken after a 30-day diet diet for 'spiritual travel' and dreams of flying, yet it is said to not cause visions. Bark from the side of the tree facing the morning sun is harvested, and 100-200g is ground and infused in water overnight. The next day, the liquid is strained, blessed with icaros by a shaman, and consumed. Partly due to the sturdy nature of the tree, it is used as a magical plant for defense (Bear & Vasquez 2000; Luna 1984; McKenna et al. 1995).

Cephalocereus melanostele (Cactaceae) has been claimed to contain *mescaline* (Rätsch 1992, citing Jiminez, A.C. 1977. Folklore Americana 23:89-100), which may be in error.

Cereus acranthus and C. peruvianus [C. repandus] (Cactaceae) have been claimed to contain *mescaline* (Rätsch 1992, citing Jiminez, A.C. 1977. Folklore Americana 23:89-100), which may be in error. C. peruvianus has often been sold misrepresented as **Trichocereus** peruvianus [even though they look quite different from one another] (pers. obs.). It has been found to contain *tyramine* (Agurell 1969a).

Cheilanthes ferruginea (Polypodiaceae), 'cola de zorra', is a fern used to treat epilepsy in Mexico; in animals, CNS-depressant effects have been observed (Heffern 1974).

Choisya ternata (Rutaceae), 'flor de clavo', is sometimes used in southern Mexico as a sedative antispasmodic, to relieve nervous excitement (Heffern 1974).

Chondrodendron tomentosum (Menispermaceae), 'pareira brava' or 'amphihuasca' ['poison vine'], is used in Brazil to treat madness and dropsy. Otherwise, it is used in n.w. Amazonia to preparae 'curare' arrow poisons for hunting, as are the barks or stems of C. iniquitanum, C. limaciifolium, C. platyphyllum and C. toxiferum (Schultes & Raffauf 1990).

'Chundur', an unidentified plant, is regarded as very important in Paez magic, for which the tuberous root swellings are chewed. Varieties with more swollen roots are known as 'chundur ñúsha' or 'chundur de Castilla'; those with thinner, more fibrous roots are known as 'chundur de arco' or simply 'chundur' (Antonil 1978).

Columnea picta (Gesneriaceae) leaves are sometimes smoked as a stimulant tobacco substitute [see **Nicotiana**] by the Siona-Secoya of Ecuador (Schultes & Raffauf 1990).

Copaifera spp. (Leguminosae/Caesalpiniaceae) are used in S. America to produce oleoresin known as 'copaíba', which is taken externally and internally as a medicine. Amongst its many curative properties, it is regarded as an aphrodisiac (Plowden 2004).

Cotyledon caespitosa (Crassulaceae) is known as 'peyote' by the Tarahumara, and is believed to cause insanity; it contains "a powerful glycoside" (Schultes 1937a, 1937b).

Coutaria latiflora (Rubiaceae), as 'colpalchi de jojulta', is used in Mexico as a tranquilliser and febrifuge (Jiu 1966).

Cranichis speciosa (Orchidaceae) has been known as 'peyote cimarrón' (Schultes 1937b) and 'peyote' (Smith 2000) [see **Lophophora**], though it is not known whether this orchid has medicinal or psychotropic uses.

Croton zehntneri (Euphorbiaceae) is used in Brazilian folk medicine – the bark and leaves are infused to treat nervous and gastric disturbances. The essential oil of the plant contains primarily *estragole* [59%], *anethole* [27%] and *methyleugenol*. Oil of the seeds of some species is very toxic. Stem bark of C. ururucana [the red sap of which is called 'sangre de drago', or 'dragon's blood' – used to heal wounds] contains clerodane diterpenes of unknown activity (Albuquerque et al. 1995; Batatinha et al. 1995; Peres et al. 1998). An unidentified Croton sp. might represent the 'tipuru' sometimes added to ayahuasca by the Shuar (Bennett 1992). The essential oil of C. nepetaefolius contains *elemicin* (Harborne & Baxter ed. 1993).

Dioon edule (Cycadaceae), known as 'hierba loca' and 'chamal' in Mexico, is known to intoxicate animals, making them act unusually, and is thus reputed to be psychoactive. Seeds are used locally to treat neuralgia. Flavonoids are found in the plant, mainly amentoflavone (Rätsch 1998;

Schultes & Hofmann 1980), a BZ-receptor ligand (Nielsen et al. 1988).

Echinocactus visnaga (Cactaceae) has been proposed to have been the unidentified 'aikutsi' plant of the Huichol, which was sometimes eaten with peyote [see **Lophophora**] to "prevent one from becoming too intoxicated" (Smith 2000). However, E. visnaga might not be a valid name (Trout ed. 1999). The common 'golden barrel cactus' E. grusonii has been sold as 'peyote' in a Mexico City market, probably for medicinal purposes (Smith 2000). In ancient Mexico, some Echinocactus spp. were important in religious rituals, and were known as 'comitl', 'huitznahuac' and/or 'metzollin'; some were even considered to be incarnations of Tlaloc, the rain god [see also **Mammillaria**]. Spines of an Echinocactus sp. were possibly used in sacrificial rituals in the temple of Huitznahuacteopan (Bravo 1937). E. polycephalus may contain extreme traces of *mescaline* (Gennaro et al. 1996), though this was not clearly indicated. E. polycephalus var. xeranthoides and E. caespitosus were found to contain unidentified alkaloids (Brown et al. 1968).

Echinocystis lobata (Cucurbitaceae), a 'wild cucumber' [see **Momordica**], grows in Mexico where the unripe seeds have apparently caused "hallucinogenic intoxication" in children who have eaten them (Heffern 1974). One psychonaut has also claimed that a tea made from the roots of what was probably E. lobata produces effects similar to those from ingesting mushrooms containing *psilocybin* and/or *psilocin* (B.K. 1998).

Enterolobium cyclocarpum (Leguminosae) is a fragrant plant called 'hueynacaztli' in the Badiano Codex; it might represent the Aztec 'teonacaztli' mentioned in the Florentino Codex, which is said to "intoxicate like the mushrooms" [see also **Cymbopetalum**] (Diaz 1979).

Espostoa lanata (Cactaceae), commonly called 'Peruvian old man cactus', is known as 'pishcol negro' where it grows in the Huancabamba Valley of Peru [see also **Armatocereus**]; it has been proposed to possibly be used in the same manner as **Trichocereus** pachanoi, though there does not seem to be any evidence for this (Smith 2000). Ethanol extracts gave negative reactions when tested for presence of alkaloids with Mayer's reagent; E. huanucensis has yielded 0.004% *tyramine*, 0.002% N-methyl-*tyramine*, 0.002% *hordenine* and traces of two other alkaloids (Mata et al. 1976).

Fabiana imbricata (Solanaceae), 'pichi-pichi' or 'k'oa', is burned as incense in the Andes of n. Chile to dispel evil spirits and ward off disease; in higher doses, it may be intoxicating. The twigs contain *scopoletin*, and the entire plant contains an alkaloid [fabianine] and an essential oil (Rätsch 1992, 1998).

Ficus insipida (Moraceae), 'ojé' or 'renaco', is used for its latex in some parts of the n.w. Amazon. When consumed under diet, it is said to be a very powerful plant-teacher. The latex is also a strong purgative; it is usually taken for this purpose mixed with 'aguardiente' liquor [2tsp per bottle], in a dose of 1tsp 3 times a day. It is also sometimes added to ayahuasca [see **Banisteriopsis**], and contains biphenylhexahydroindolizines and phenanthroxoindolizines. F. ruiziana ['renaco'] is also sometimes used in ayahuasca, and contains triterpenes and furocoumarins. The juice of the shoots of Ficus spp. may be taken under a 6 month diet, to be able to "travel under the water", where shamanic knowledge is learned (Bear & Vasquez 2000; Desmarchelier et al. 1996; Luna 1984; McKenna et al. 1995; Schultes & Raffauf 1990). A Ficus sp. known as 'renaquilla' is used by the Shipibo, who ingest it under special diet conditions, so that the female spirit of the plant will teach them to heal in their dreams (Luna & Amaringo 1991). F. anthelmintica fruit is taken in Brazil as an aphrodisiac and memory stimulant, and F. atrox latex is used as an ingredient of one 'curare' arrow poison (Schultes & Raffauf 1990). The Nkopo of PNG use F. gul ['kildsek'] in their initiations, and they use another Ficus sp. ['kwanam'] in rituals to achieve harmony with natural forces (Schmid 1991). In that continent, the use of Ficus spp. in rain magic and to combat sorcery is widespread (Paijmans ed. 1976). The Mbowamb of Mt. Hagen eat leaves of a Ficus sp. ['mbon'] to protect against the 'spell of death' (Stopp 1963). On Rossel Island, near PNG, F. subnervosa leaves are chewed as a betel nut substitute [see **Areca**] (Thomas 2001a). In Africa, Zulu men drink a decoction of F. soldanella bark as a 'strengthening tonic' (Watt & Breyer-Brandwijk 1932). In some parts of Africa, unspecified parts of F. sur have been used as a homicidal poison (De Smet 1998). The *phenethylamine* alkaloid synephrine has been obtained from the 'banyan tree', F. bengalensis [0.0081% (w/w) from leaves] (Wheaton & Stewart 1970), which is considered sacred in India and Sri Lanka (Schultes & Raffauf 1990).

A Fuchsia sp. (Onagraceae), 'contrahechizo' [a name shared by **Iochroma** grandiflorum, which is used in the same way], is sometimes added to **Trichocereus** pachanoi brews in Peru (Rätsch 1998).

Gloeospermum sphaerocarpum (Violaceae), 'tamarillo' [not to be confused with Cyphomandra betacea (Solanaceae), whose fruits are the common tamarillo or 'tree tomato'], is used by the Waunana in the Amazon, drinking a cold water leaf infusion as a "ceremonial hallucinogen" (Duke & Vasquez 1994).

Guaiacum [Guayacum] sanctum (Zygophyllaceae) wood ['guayaca wood'] is used in c. America as an aphrodisiac and to treat intestinal worms; in Europe it was also used to treat syphilis. The wood contains an aromatic resin (Rätsch 1990). See also G. officinale in *Methods of Ingestion*.

Gymnocactus beguinii (Cactaceae) was recently shown to contain 0.0004-0.0012% *mescaline* by fresh weight (Gennaro et al. 1996), as well as N-methyl-*phenethylamine*, N-methyl-*tyramine* and *hordenine* (West et al. 1974).

Heisteria pallida (Olacaceae), 'chuchuhuasi' [see also **Maytenus**], is used by the Machiguenga of the Amazon for its stem bark, which acts as a male aphrodisiac (Desmarchelier et al. 1996).

Helenium mexicanum (Compositae) is known as 'yerba de las ánimas' ['herb of souls'] in Mexico, though it is not known to be used as a psychotrope (Diaz 1979).

Helianthus annuus (Compositae), 'sunflower', is a well-known central American plant; besides its nutritious seeds, the flower petals have been used to treat rheumatism and gastrointestinal problems, but most interestingly the Mayans made an aphrodisiac drink from them. It has been suggested they may have the same effect cooked in oil and eaten with salt and pepper. Petals and leaves contain *chlorogenic acid*; seeds contain vitamin E, which might also act as a sexual nutrient (Rätsch 1990).

Hiposma carnea (Convolvulaceae), known as 'chalviande' and 'matacabra' ['goat killer'], has been said to be used as a "hallucinogen" around coastal Ecuador, but this may be a confusion with **Ipomoea** carnea (Rätsch 1998).

Hura crepitans (Euphorbiaceae), 'catahua', is used as for Ficus insipida [see above]. The Tikuna know it as 'wa-chee-va', and use the fermented latex as a potent fish-poison. It has also been used as an ayahuasca additive [see **Banisteriopsis**], and in Peru is taken alone as a 'powerful plant teacher'. To consume the plant, a diet must be kept for up to several months [if you wish to avoid the possibility of death]; a reliable shaman cooks the latex carefully in a double-boiler, and sings potent 'icaros' over it. When slightly gelatinous, a few mls are consumed. The resin is said to 'burn the intestines', though this is less pronounced when properly prepared. Over time, the plant strengthens one, and protects against sorcery when taken in this way. It contains tigliane diterpenes, lectins and piscicidal compounds (Bear & Vasquez 2000; Desmarchelier et al. 1996; Luna 1984; Luna & Amaringo 1991; McKenna et al. 1995; Trout ed. 1998).

Hymenaea courbaril (Leguminosae/Caesalpiniaceae) trunk resin is used as a source of 'copal' incense in Mexico; as well as mundane medicinal uses, this and other copals are important in divination and other rituals (Case et al. 2003).

An Iresine sp. (Amaranthaceae) is sometimes added to ayahuasca [see **Banisteriopsis**] in s. Colombia (Schultes 1967a). Members of the genus are reputed to 'cure insanity' (Schultes & Hofmann 1992). In n. Argentina, I. diffusa stalks are sometimes used to prepare the alkaline reagent used with coca [see **Erythroxylum**] (Hilgert 2001). An Iresine sp. [perhaps I. celosia] is reputedly sometimes added to **Trichocereus** pachanoi brews, along with other plants (Davis 1983; Schultes & Hofmann 1992). I. celosia and I. herbstii are known as 'borrachera' ['intoxicant'] in the Sibundoy Valley of Colombia (Bristol 1969), and in Huancabamba, Peru I. celosia is known as 'timora' (Davis 1983) and is reputedly 'magic and dangerous' (Schultes 1967a). In n.e. Peru I. herbstii is known as 'cimora señorita', and has been used by rural people for 'black magic', sometimes "to take possession of another's identity". It is said to be used by shamans with San Pedro [see **Trichocereus**] for divination and diagnosis. Aerial parts are used to treat skin conditions and fever; a water extract has sedative effects in mice (De Feo 2003; De Feo et al. 1996). Some Iresine spp. contain cinnamic acid amides (McKenna et al. 1995).

Juanulloa ochracea (Solanaceae) is known as 'ayahuasca' in Colombia [see **Banisteriopsis**], and might be an additive to ayahuasca, or an inebriant in its own right. The Karijona of the Rio Apaporis say that it has 'magical properties'. The trunk and leaves are normally used to treat wounds. The alkaloid parquine [see **Cestrum**] has been found in the genus (Schultes 1972; Schultes & Raffauf 1990).

Kyllinga brevifolia (Cyperaceae) rhizome is used in Paraguay as a sedative and to relieve stress; the rhizome extract given to mice was non-toxic orally, and caused "decrease of spontaneous motor activity, piloerection, passivity, palpebral ptosis, catatonia and a stereotyped behaviour", as well as decreased rate of respiration (Helliön-Ibarrolaa et al. 1999).

Lepidium meyenii [L. peruvianum] (Brassicaceae), 'maca' or 'Peruvian ginseng', is used in the Peruvian Andes for its tubers as an aphrodisiac, tonic, energiser, adaptogen, immunostimulant and nutritious supplement. It has more recently been marketed to the rest of the world for its medicinal virtues. Traditionally, the tubers have mainly been used as a nutritious food, from c. Peru to Bolivia and n.w. Argentina. They may also be made into an alcoholic beverage ['maca chicha'] and when dried, sometimes flavour the local sugar cane rum or 'aguardiente' (Muhammad et al. 2002; Ochoa & Ugent 2001; http://rain-tree.com/maca.html). Leaves, sprouts, hypocotyls and seeds contain glucosinolates [see **Brassica**], such as benzylglucosinolate and p-MeO-benzylglucosinolate (Li et al. 2001). Tubers have yielded the pyridine alkaloid macaridine, and alkamides named macamides (Muhammad et al. 2002), as well as saponins, tannins, sugars, starches, fatty acids, 13-16% protein and minerals such as iron and iodine (Ochoa & Ugent 2001). The Eurasian L. sativum is used in India for its aphrodisiac seeds (Nadkarni 1976). The plant has yielded

bis-benzyl imidazole derivatives (Muhammad et al. 2002).

Leucaena guatemalensis (Leguminosae) has been known as 'yajé' in Guatemala [see **Banisteriopsis**] (Trout ed. 1998); although suggestive of some psychotropic properties associated with ayahuasca, this is unusual because the beverage is not known to have been prepared or consumed there traditionally.

A Loricaria sp. (Compositae) known as 'corona de cristo' is used in Peru for its aerial parts, which are infused in sugared water and drunk to treat "physical and psychological weakness and anemia" (De Feo 2003).

Lucuma salicifolia (Sapotaceae), as 'zapote borrachero', is used in Mexico as a soporific and anti-periodic (Djerassi et al. 1956; Jiu 1966). The fruit flesh can bring about an alcohol-like inebriation, and is sometimes added to brandy or cheap alcohol to make it more intoxicating (Rätsch 1998). See also **Casimiroa**.

Matayba guianensis (Sapindaceae), 'para-para' from Venezuela, is reported to have toxic fruits that can make the consumer 'crazy' (Rätsch 1998).

Matucana madisoniorum [Borzicactus madisoniorum, Submatucana madisoniorum] (Cactaceae) has been claimed anecdotally, from numerous sources, to be used by shamans in Peru, in combination with **Trichocereus** pachanoi, and possibly also by itself. It is unclear, however, whether this cactus fulfils a visionary purpose, though more definite information is apparently nearing publication. This plant, similar in appearance to **Lophophora** williamsii, is also rumoured to contain *mescaline* (Smith 2000). At the time of writing it seems likely that these rumours may be unsubstantiated. A recent GC-MS analysis of this species could not detect any *mescaline* (Trout pers. comm.). A human bioassay of two old, cultivated specimens [c.190g] resulted in no noticeable psychoactivity (Stuart 2002).

Melocactus peruvianus (Cactaceae) has been claimed to contain *mescaline* (Rätsch 1992, citing Jiminez, A.C. 1977. Folklore Americana 23:89-100), which may be in error.

Metteniusa edulis [Pentandria monogynia] and M. nucifera (Metteniusaceae; sometimes assigned to Alangiaceae or Icacinaceae), known as 'canyí', are ritually important to the Kogi of Colombia, whose shamans regard the fruits as being a strong psychotrope. However, in Venezuela M. edulis fruits are eaten after cooking as a [presumably] harmless food (Rätsch 1998).

Miconia willdenowii (Melastomataceae) leaves are used as a tea substitute [see **Camellia**] in Brazil. They have yielded 0.2% *caffeine* (Lewis & Elvin-Lewis 1977).

'Murcuhuasca' or 'murcohuasca', either Marcgravia williamsii (Marcgraviaceae) or Rourea amazonica (Connaraceae) (Luna & Amaringo 1991), is a Peruvian vine which may be taken under a strict 1-2 month diet to become agile and "gain the ability to travel very rapidly through the jungle". The parts used are small ball-like sap deposits found within the stem (Bear & Vasquez 2000).

Myrcia acuminata [M. fallax] (Myrtaceae), 'umsim' or 'yacuma negra', is considered a powerful magical herb by the Paez, who chew its seeds with coca [see **Erythroxylum**] for pútia rituals (spitting a spray of masticated coca, sometimes with tobacco [see **Nicotiana**] and aguardiente, for the purposes of blessing or ritual cleansing) (Antonil 1978).

Myroxylon balsamum [M. pereirae] (Leguminosae), 'ta'atsa' or 'tache' [a.k.a. 'balsam of Peru'], is used by some Paez shamans for its seeds, which are chewed and regarded as "powerful". The resin from this tree was used in the past as an incense to repel insects (Antonil 1978).

Nectandra acutifolia (Lauraceae) is used by the Kubeo of n.w. Amazonia in the form of a bark and leaf decoction, which acts as a strong stimulant for elderly people suffering fatigue or narcolepsy. Contains alkaloids, and essential oil in its leaves (Schultes 1993). N. megapotamica from São Paulo state, Brazil, has yielded 0.01% *N-methyltryptamine* and 0.0042% N-methyl-*pinoline* from the bark; the plant is used locally to relieve pain (Filho & Gilbert 1975); N. polita wood has yielded *eugenol*, *methyleugenol*, dehydrodieugenol, O-methyldehydrodieugenol and di-O-methyldehydrodieugenol (Suarez et al. 1983). N. pichurim is known as 'canélla' [see **Canella, Drimys**], 'purchury bean' and 'pichurim' [see **Licaria**].

Neoraimondia macrostibas (Cactaceae) might sometimes be added to **Trichocereus** pachanoi brews in Peru, reputedly as part of the mysterious 'cimora' complex [see **Trichocereus**] (Schultes 1967a). Neoraimondia spp. have been depicted in Nazca and Moche ceramic artwork, particularly in relation to the edible fruits (Ostolaza 1997, 1998). This species has also been known as N. aticensis, N. gigantea, N. peruviana, N. roseiflora and N. arequipensis. N. arequipensis var. roseiflora was shown to contain less than 0.01% each of *DMPEA* and 4-OH-3,5-dimethoxy-*phenethylamine* (Ma et al. 1986). N. macrostibas has been claimed to contain *mescaline* (Rätsch 1992, citing Jiminez, A.C. 1977. Folklore Americana 23:89-100), which may be in error.

'Ninacaspi' (Gramineae?; unidentified) is a small bamboo-like plant, which may be taken under diet as a plant teacher. It may be prepared by crushing c.20 stems, with leaves attached, and boiling thoroughly in water. Initial effects consist of unpleasant stomach sensations and feelings of extreme heat, followed by a visionary stage (Bear & Vasquez 2000).

Niphogeton scabra (Umbelliferae), as 'hornamo toro', is sometimes added to **Trichocereus** pachanoi brews in Peru (Rätsch 1998).

Obregonia denegrii (Cactaceae) is another 'peyotillo' with superficial resemblance to peyote [**Lophophora**]; it has yielded 0.01-0.1% [w/w] alkaloids, mostly *tyramine*, with lesser amounts of *hordenine*, traces of N-methyl-*tyramine* and unidentified compounds (Bruhn & Bruhn 1973).

Ocotea pretiosa [O. cymbarum] (Lauraceae) trunk-wood is used to obtain 'Brazilian sassafras oil' [see **Sassafras**], though it is less used now due to over-harvesting. Trees from the region in which it was most harvested [the state of Santa Catarina] are rich in *safrole* (FAO 1995); the species has also yielded O-*methyleugenol* (Harborne & Baxter ed. 1993) and *phenethylamine* (Smith 1977a). *Apiole* is found in Ocotea spp. (Harborne & Baxter ed. 1993). In the Mitú region of Amazonia, O. opifera fruits are mixed with coca powder [see **Erythroxylum**] to increase its strength, when taken "for certain dances". The Kubeo burn leaves of O. simulans to prepare an ash for use with coca "for certain ceremonies"; this ash is said to make the coca 'stronger' and to add a pleasant taste. The Kofán use O. venenosa fruit in one of their arrow poisons (Schultes & Raffauf 1990). In Africa, the Zulu snuff the powdered bark, or inhale the smoke, from O. bullata to relieve headaches (Watt & Breyer-Brandwijk 1962).

An Onoseris sp. (Compositae), as 'hornamo blanco', has been tentatively identified as an additive to **Trichocereus** pachanoi brews in Peru (Rätsch 1998).

Orthomene schomburgkii (Menispermaceae) is used by the Kofán as a soporific, in the form of a leaf tea. The Tikuna use the bark mixed with Anomospermum reticulatum [see above] to prepare one of their 'curare' arrow poisons (Schultes & Raffauf 1990).

Ovidia pillopillo (Thymelaeaceae) is reportedly one of the four major 'hallucinogens' used by the Mapuche of Chile (Rätsch 2001).

Pagamea macrophylla (Rubiaceae) from Colombia is known as 'manu-su-ka-ta' to the Barasana, and as 'ma-na-shu-ke-ma' to the Makuna. Barasana medicine men have been reported to snuff the powdered leaves during divination rituals, though it is not known what effect is produced by the snuff. The Barasana also commonly use a tea of the leaves and bark to remedy the stomach bleeding which may result from their heavy use of coca [see **Erythroxylum**]. The plant is regarded as toxic by the Makuna. The related P. coriacea is used by the Taiwano as a strong stimulant, to restore use of the legs in elderly people. For this purpose, the bark is scraped from young branches, and when still fresh, decocted; this tea is drunk over several weeks. Stems and leaves have given a negative result in one alkaloid screening; Schultes obtained a positive result from a spot-test on fresh leaves. Chemistry of the genus is otherwise unknown (Schultes 1980). Based on its seemingly shamanic useage and relation to **Psychotria**, P. macrophylla has been suspected of containing *tryptamine* alkaloids (Ott 1993).

Parkia spp. (Leguminosae) are known as 'paricà' in parts of Brazil [see **Anadenanthera**, **Virola**] (Schultes 1955a).

'Pashaco' (Leguminosae; unidentified) seeds are dried, powdered and snuffed by the Yagua of Peru, in order to increase sensory acuity for hunting. When ground with the dried or toasted seeds of 'bubinsana' [see **Calliandra**], the snuff is said to produce visionary effects. Sometimes this is fortified with the dried and powdered venom of a 'poisonous toad' [which may refer to a frog – see **Phyllomedusa**] – "Sniffing about one gram of this powder, they would enter into an ecstatic flight. It would also open up their noses to smell more clearly" (Bear & Vasquez 2000). Albizzia spp. [see below], Parkia spp., Macrolobium acacaefolium and Schizolobium excelsum [see below] [all from the Leguminosae] have been commonly known as 'pashaco'. Derivations of this name have also been used – Albizzia spp. as 'pashaco blanco', **Acacia** spp. as 'ura pashaco', Parkia igneiflora as 'goma pashaco', P. multijuga as 'pashaco curtidor', and P. pendida as 'pashaco colorado'.

Pelaea cordata (Polypodiaceae) is thought to have been used by the Nahua of Mexico as an inebriant, though this is in need of confirmation (Diaz 1979).

Peperomia spp. (Piperaceae) – two unidentified species, known as 'shugués' and 'shupeñín', are sometimes chewed fresh with coca [see **Erythroxylum**] by Paez shamans of high-altitude regions, usually also with another unidentified plant ['shulape'], and less frequently today, a Sphagnum sp. ['shu'] (Antonil 1978). Peperomia spp. are thought to represent 'tsemtsem', a plant used by some Shuar groups as a 'mild hallucinogen'. It is given to children so that they may contact their soul or 'arutam' (Bennett 1992). As 'congona' or 'piri-piri' [see **Cyperus**, **Balansia**], P. flavamenta, P. galioides and perhaps other Peperomia spp. are sometimes taken with San Pedro [see **Trichocereus**] in Peru. This addition is said to lend a feeling of clarity and brightness to the San Pedro experience (Rätsch 1998). Some Peperomia spp. contain alkaloids (Schultes & Raffauf 1990) and essential oils (Rätsch 1998).

Persea americana (Lauraceae) is best known for its fruit [avocado], though the peel is regarded to be excitant and aphrodisiac in Mexico (Heffern 1974); the seed and fruit flesh have also been claimed to be aphrodisiac (Rätsch 1990). In the leaves, *estragole* has been detected in large quantities of Mexican cultivars, but not those from West Indies or Guatemala (King & Knight 1987). The whole fruit yielded 0.001% *serot-*

onin, 0.0023% *tyramine* and 0.0004-0.0005% *dopamine* (Udenfriend et al. 1959). In the Canary Islands, the related P. indica is known to be intoxicating, and it is said this effect can even be passed on from sleeping under the tree, or handling the wood. Goats eat the bark and leaves habitually to become intoxicated, though too much can kill. It is not used by local humans due to its toxicity (De Vries 1993). P. gratissima bark has been found to contain *estragole* in its essential oil (Harborne & Baxter ed. 1993), and the seed has been taken in Amazonia as a contraceptive (Schultes & Raffauf 1990).

Petiveria alliacea (Phytolaccaceae), 'zorillo' [also known as 'pachyé', 'hierba de las gallinitas'], is used in Mexico to treat hysteria, nervous disorders and numbness, and as an antispasmodic (Heffern 1974). In Peru, it is known as 'mucura', and may be taken under diet as a plant teacher; it is also sometimes added to ayahuasca by Yagua shamans (Luna 1984; McKenna et al. 1995). The plant is used as an ingredient in some Haitian zombi antidotes [see *Methods of Ingestion*], and also reputedly has aphrodisiac properties (Davis 1988a). It has yielded trithiolanes, oligo sulfides and triterpenes (McKenna et al. 1995).

Peumus boldus (Monimiaceae) ['boldo'] from Chile and Peru [also naturalised in w. US, and the Mediterranean region] is a liver tonic commonly drunk as a tea in Argentina, but the foliage is said to have hypnotic, analgesic, and perhaps 'hallucinogenic' effects when taken in larger amounts. It contains c.0.25-0.535% alkaloids, including c.0.1% [of leaf] boldine [a hypnotic sedative, and analgesic as potent as *cocaine*, causing excitation and even respiratory paralysis in acute doses], sparteine [see **Cytisus**] and pachycarpine, as well as boldoglucin, ascaridol, and 2-2.6% of an essential oil. The leaves have been administered by healers in Chile, rolled into a cud with two types of seaweed [a Gracilaria sp. and Durvillaea antarctica] (Chevallier 1996; Gore 1997; pers. comm.; Schindler 1958).

Pfaffia paniculata [Gomphrena paniculata] (Amaranthaceae) is known as 'suma', or 'Brazilian ginseng', and its roots are used in Brazil [and today in other parts of the world, such as Australia] as a ginseng-like tonic, adaptogen, and aphrodisiac [see **Panax**], as well as an antidiabetic remedy; it has yielded 11% nortriterpenoid saponin glycosides [including pfaffosides], allantoin, stigmasterol, sitosterol, germanium, vitamins, amino acids, electrolytes and trace minerals (Nishimoto et al. 1984; Schultes & Raffauf 1990; http://www.rain-tree.com/suma.htm). It has been shown to improve the sexual performance of 'sexually sluggish' or impotent rats, whilst having no discernable effect on potent rats (Arletti et al. 1999). P. iresinoides ['marosa'] has been used by the Shipibo as an entheogen, but its use is fading; it is also used to prepare for the ayahuasca ceremony [see **Banisteriopsis**] (Trout ed. 1998 citing Amazonia Peruana 5(10):91-118 [1984]). In Paraguay, roots of the related P. glomerata ['vatatilla', 'little sweet potato'] are macerated or infused to make a refreshing, diuretic beverage (Basualdo et al. 1995). In rodents, an alcohol extract of P. glomerata roots was shown to act as a CNS-depressant when given i.p., but appeared to be inactive orally in this regard (De Parisa et al. 2000).

Philodendron scandens (Araceae), 'heartleaf philodendron', has reportedly been used in Peru as a "narcotic[...] to induce sleep". It has allergenic properties and contains 5-heptadecatrin-8(Z),11(Z),14(Z)-benzylresorcinol (Rätsch 1998).

Pinus pseudostrobos (Pinaceae), 'pitch pine', is thought to be the source of the 'pom' incense resin used by the Lacandon Maya [previously identified as Protium copal - see below]. It is ritually burnt as an offering to the gods, who are said to consume the fumes as their main form of food (Case et al. 2003). In Nepal, Pinus spp. ['salla'] such as P. roxburghii and P. wallichiana are sometimes used for incense by shamans (Müller-Ebeling et al. 2002). *Estragole* has been found in Pinus spp., and *methyleugenol* in P. sylvestris (Harborne & Baxter ed. 1993). P. contorta, P. nigra, P. ponderosa and P. sylvestris contain piperidine alkaloids (Stermitz et al. 2000).

Piqueria trinervia (Compositae), as 'hierba de San Nicholas', is used in Mexico as a depressant; it also treats rheumatism and fever (Jiu 1966).

Piscidia erythrina [P. piscipula] (Leguminosae), known variously as 'Jamaica dogwood', 'fish poison tree' and 'fish fuddle', has been used as an opium substitute [see **Papaver**]. Roughly 20 drops of a fluid extract of the plant were said to be "more decidedly hypnotic than opium", though with a shorter duration of action. It was reported to produce no anorexia, headache, constipation or digestive disturbance (Anon. 1881d).

A Pleurothallis sp. or an Epidendrum (Epidendron) sp. (Orchidaceae), as 'hornamo caballero', has been tentatively identified as an additive to **Trichocereus** pachanoi brews in Peru (Rätsch 1998); E. radiatum reportedly has a 'narcotic' smell, but this could either be descriptive of the odour or of its effects when inhaled. In Mexico, E. pastoris bulbs have been used to make a salep substitute [see above] (Lawler 1984). Alkaloids have been found in both genera (Lüning 1967).

Plumeria rubra (Apocynaceae) flowers were used by the Aztecs to relieve fatigue and dispel fear (Heffern 1974).

A Polypodium sp. (Polypodiaceae) tree fern, known as 'incapcocam', 'cucacuca' and 'coca del Inca', was reputedly used by the Incas as a coca-substitute [see **Erythroxylum**], and is also said to be used instead of tobacco [**Nicotiana**] to 'clear the head'. Roots of another unidentified Polypodium spp. have been taken orally with **Anadenanthera** colubrina seeds (Rätsch 1998). Roots of the common 'oak fern' P. vulgare have been claimed to contain *glycyrrhizin* (Grieve 1931).

Pourouma cecropiaefolia (Moraceae), 'uvilla', is used in Amazonia when **Cecropia** is not available; the leaves are burnt to ash and used with powdered coca [see **Erythroxylum**]. Root scrapings infused in water are reputed to cause permanent sterility (Schultes & Raffauf 1990).

Protium spp. (Burseraceae) such as P. copal ['pom', 'copal negro'] are amongst a variety of Central American trees whose resins are used as 'copal' incense, used to communicate with the gods as well as for a wide range of other ritual and medicinal applications. The Brazilian P. heptaphyllum has yielded *diallapiole* (Case et al. 2003).

A Pseuderanthemum sp. (Acanthaceae) known as 'dormidero' is reported to be used as a narcotic in Peru (Rätsch 1998).

Quararibea funebris (Bombaceae) flowers have been suggested to represent the Aztec drug 'poyomatli', and the Zapotecs once held funerary rites under the branches of the tree. The highly aromatic flowers ['flor de cacao'] are used today in Oaxaca as a spice additive to drinks made from cacao [see **Theobroma**], called 'ponzonque' or 'tejate'. They are also used in local folk medicine, to 'control psychopathic fears', relieve coughs, and regulate menstruation (Raffauf et al. 1984; Rosengarten 1977). Preliminary tests by some have not yet revealed psychoactivity (Ott 1993), though these people might have been expecting a visionary experience. One psychonaut reported '*GHB*-like' euphoric effects from a tea made from several grams of the flowers (theobromus pers. comm.). The flowers contain compounds derived from γ-butyrolactones, such as the quabalactones, and the novel pyrrole lactone alkaloids funebral, funebrine and funebradiol (Raffauf et al. 1984; Zennie & Cassady 1990; Zennie et al. 1986). An unidentified Quararibea sp. from Peru, called 'espingo' or 'ispincu', is used for its seeds as a shamanic inebriant. It may also be added to ayahuasca or **Trichocereus** preparations [as 'ishpingo'] (Ott 1993). Q. putumayensis is also used to make 'curare' arrow poisons by the Kofán of n.w. Amazonia (Schultes & Raffauf 1990).

Retiniphyllum concolor (Rubiaceae), known in the Amazon as 'o-no-ka' or 'ka-hoon-cha'', is known to be a 'strong witchcraft plant', and is suspected of being mildly psychoactive. Some tribes burn it for the smoke to have purifying and therapeutic effects in cases of tuberculosis (Schultes & Raffauf 1990).

Rheedia macrophylla (Clusiaceae), 'achuni-caspi' or 'achuni-casha', is used in the Amazon as a powerful male aphrodisiac, as well as for sorcery and love magic (Luna & Amaringo 1991).

Rivinia humilis (Phytolaccaceae) ['coralillo', 'hierba mora'] is suspected of being the Aztec inebriant 'amatlaxiotl' mentioned in the Florentine Codex, though further investigation is needed (Diaz 1979).

Rollinia mucosa (Annonaceae) ['anonillo', 'anonita del monte', 'cherimoya'] is a Mexican tree, whose edible fruits are used in local medicine. The seeds have been found to contain new and interesting *tryptamine* alkaloids of unknown pharmacology – N-palmitoyl-*tryptamine*, N-stearoyl-*tryptamine*, N-arachidoyl-*tryptamine*, N-behenoyl-*tryptamine*, N-tricosanoyl-*tryptamine*, N-lignoceroyl-*tryptamine*, N-cerotoyl-*tryptamine* and N-pentacosanoyl-*tryptamine* [as well as lignans and acetogenins] (Chávez 1999).

Rudgea retifolia (Rubiaceae) is known in Peru as 'chacruna', a name usually applied to **Psychotria** spp., and may have once been used for similar purposes as an ayahuasca additive [see **Banisteriopsis**] (Ott 1993).

Ruellia albicaulis (Acanthaceae), 'hierba del chivo', is decocted in Mexico as a "potent aphrodisiac" (Heffern 1974).

Sanango racemosa [S. durum; Gomara racemosa; Gomaranthus racemosa] (Loganiaceae) leaf is used as 'sanango' in the Peruvian Amazon as an inebriant; little more is known (Rätsch 1998). I am unsure whether there is some confusion here with the unrelated plants known by the same common name [see **Tabernaemontana**].

A Sanchezia sp. (Acanthaceae) known as 'cimora macanche' is regarded in n.e. Peru as a 'powerful cimora' [see **Trichocereus**]; it is used by young people as a psychoactive drug. Another unidentified Sanchezia sp., perhaps the same one, has been claimed "to have hallucinogenic properties when smoked" (De Feo 2003; Schultes & Raffauf 1990).

Schizolobium amazonicum and S. parahybum (Leguminosae) are known as 'paricà' in parts of Brazil [see **Anadenanthera**, **Virola**] (Schultes 1955a).

Scleria catharinensis (Cyperaceae), 'yuts-kái' or 'curíbano', bears a root with a strong taste, sometimes chewed with coca [see **Erythroxylum**] by Paez shamans, considered to add to the power of the shaman; however, some Paez shamans consider it to be dangerous and confine its use to that of sorcery. A related variety or species, unidentified, is known as 'chindaalco' or 'pata de perro'; its root is more swollen and bears a "rather more pleasant and musky flavour", and may be used in the same way. Both are infused to treat stomach complaints (Antonil 1978).

Scoparia dulcis (Scrophulariaceae), 'sweet broom', is also known as 'vacourinha', and used as an antispasmodic (Grieve 1931); in the Amazon, as 'bati matoshi' or 'piqui pichana', the leaves are smoked as a **Cannabis**-substitute (Duke & Vasquez 1994).

Sebastiana pavonia (Euphorbiaceae) is claimed to be 'hallucinogen-

ic', and the crushed seeds are said to have been used as a fortifying tonic by the Yaqui of Mexico (Rätsch 1998). The Tarahumara sometimes use S. pringlei bark to stupefy fish (Pennington 1958).

Selenicereus grandiflorus [Cactus grandiflorus, Cereus grandiflorus] (Cactaceae), 'night-blooming cereus' or 'queen of the night', is often confused with **Epiphyllum**. The flowers and young stems, harvested in summer and immediately made into a tincture, have been used as a heart tonic. They also treat rheumatism, and the juice of the plant has been used in the Caribbean as an anthelmintic (Chevallier 1996; Felter & Lloyd 1898). In large doses, the tincture "produces gastric irritation, and also affects the brain, causing confusion of mind, hallucination, and slight delirium. In excessive doses, a quickened pulse, constrictive headache, or constrictive sensation in the chest, cardiac pain with palpitation, vertigo, dimness of sight, over-sensitiveness to noises, and a disposition to be sad or to imagine evil, are among its many nervous manifestations" (Felter & Lloyd 1898). The plant has yielded 0.3% *tyramine* and *hordenine* (Trout ed. 1999), as well as the flavonoid isorhamnetin (Chevallier 1996); an early study observed 7 unidentified alkaloids (Brown et al. 1968). Modern-day psychonauts have reportedly used the plant in combination with **Trichocereus** pachanoi, or even as a substitute for it. One individual also reported ingesting the residue from an alcohol extract of 45cm dry S. grandiflorus, and experienced a strong stimulation (Trout pers. comm.). Given these reports it seems likely that other, more active, compounds will be found in this cactus.

Senegalia spp. (Leguminosae) are known as 'paricà' in parts of Brazil [see **Anadenanthera**, **Virola**] (Schultes 1955a).

'Shahuan peco' (Bromeliaceae?) is an unidentified 'parasitic' [perhaps epiphytic?] plant with small, three-fingered leaves that grows in branch forks of tall trees. The Shipibo-Conibo of Peru once used it as a powerful initiatory shamanic plant. The middle leaflet was crushed and either mixed with tobacco and smoked, or mixed with tobacco water and drunk, as well as rubbing the diluted plant juice over the body. The visionary experience, said to be much stronger than that from ayahuasca, takes some 12hrs to take effect and is said to also last 12hrs (Rätsch 1998).

Sloanea laurifolia (Elaeocarpaceae), 'taque', bears fruits known as 'arepa de maiz' ['maize breads' - see Zea mays below]; in Venezuela, the fresh fruit has been reported to cause a 'loco' or 'crazy' feeling when consumed (Rätsch 1998).

Smilax spp. (Liliaceae) such as S. officinalis, generally called 'sarsaparilla', are known as a male sexual tonic; the root is consumed in Mexico as a tonic aphrodisiac, and is also an ingredient of root-beer. The herb treats skin conditions, and has been used to treat syphilis – the success of many species for this latter disease is doubtful, though the Chinese S. glabra has shown positive activity. Smilax spp. contain steroidal glycoside saponins similar to testosterone and progesterone (Chevallier 1996; Kindscher & Hurlburt 1998; Mabey et al. ed. 1990; Nadkarni 1976; Ody 1993; Schultes & Raffauf 1990).

Sphenoclea zeylanica (Sphenocleaceae) is native to Asia, but now exists in the humid tropics of both hemispheres – it is known in Colombia as 'borrachero' or 'borrachito', referring to its intoxicating properties, and has been responsible for cattle poisoning. Fresh material contains alkaloids (Schultes & Raffauf 1990).

Sterculia excelsa (Sterculiaceae), as 'mahot cochon', has reportedly been used by at least one Guianan, who made a liquid snuff from the ashes of this plant and the leaves of a wild tobacco [see **Nicotiana**] (Plotkin 1993); the described effects, however, may merely relate to the tobacco present. In w. India and Pakistan, 'tula tree' [S. alata; syn. Pterygota alata] seeds ['bekaro'] are used as an opium substitute [see **Papaver**] (Cooke 1860; Emboden 1979a; Nadkarni 1976). They are eaten in parts of Indo-China, "despite the tingling and drowsiness they cause" (Perry & Metzger 1980). Seeds of the Asian S. scaphigera contain traces of *caffeine* and *theobromine* (Keys 1976), and *caffeine* was also detected in S. platanifolia seeds (Webb 1948). HCN has also been reported from the genus (Pammel 1911). Mature seeds of S. foetida cultivated in Port Douglas, Queensland [harvested Aug.] tested positive for alkaloids (Webb 1949). S. foetida leaf, root and fruit also produce HCN (Watt & Breyer-Brandwijk 1962). An alcohol extract of the leaf acted as a hypnotic-sedative in mice, and showed antiinflammatory activity in rats (Mujumdar et al. 2000). In Ghana, the stems are decocted as an asthma treatment; preliminary animal studies have supported this useage (Noamesi et al. 1986).

Strombocactus disciformis (Cactaceae) is known as 'peyote' in Mexico [see **Lophophora**], though it is not known to have been used as a psychotrope (Bravo 1937; Bruhn & Bruhn 1973; Schultes 1937a, 1937b). It has given positive tests for the presence of alkaloids (Smith 2000).

Tabebuia heteropoda (Bignoniaceae), 'tahuari', is sometimes added to ayahuasca [see **Banisteriopsis**]. Said to cause sickness or death if the special diet and sexual abstinence are broken; it contains lapachol, dibenzoxanthines, and naphthoquinones. Tobacco pipes made from a Tabebuia sp. ['tahuari'] are used to release old spirits for their curing powers. May be taken alone as a plant teacher (Luna 1984; Luna & Amaringo 1991; McKenna et al. 1995). The inner bark of the related T. lapacho [T. flavescens; Tecoma lapacho], known as 'three way', 'divine tree' or 'lapacho', also contains lapachol, and is used as a 'ginseng-like' tonic and adaptogen [see **Panax**] (Jones 1995). T. pentaphylla is known as 'amapola' ['poppy', 'opium' – see **Papaver**] in Latin America (Rätsch 1998). T. impetiginosa ['taheebo'] inner bark has yielded volatile compounds with antioxidant properties, including [d/w] 0.0034% *elemicin*, 0.0034% trans-*anethole*, 0.0053% 4-MeO-benzaldehyde, 0.004% 4-MeO-phenol and 0.003% 4-MeO-benzyl alcohol (Park et al. 2003).

A Thevetia sp. (Apocynaceae) is thought to be the identity of 'cabalonga blanca', a Colombian magical plant with psychotropic activity; it is also said to be used as an ayahuasca additive [see **Banisteriopsis**]. The 'true' cabalonga is believed to be a **Strychnos** sp. [see also **Jatropha**]. T. peruviana [T. neriifolia] is also known as 'cabalonga', 'cabalonga la huasteca', 'calabonga de tabasco', 'palo de San Antonio' and 'yellow oleander', but is not known to be psychoactive; 8-10 seeds may kill an adult (Rätsch 1998).

Tibouchina longifolia (Melastomataceae), 'palo del susto' or 'palo del espanto', is used in n.e. Peru to treat a complex psychosomatic complaint in which physical and psychological weakness result from phobias; for this, 50g of leaves are soaked in a litre of water before filtering and drinking 2-3 cups a day whilst on a vegetarian diet. After a week the effects are terminated by drinking 'arranque' [see **Citrus**] (De Feo 2003).

'Ucullucuycasha' [unidentified] from Peru may be taken under diet as a plant teacher. It causes a burning sensation [the tree is associated with the sun], physical weakness, and powerful visions (Bear & Vasquez 2000).

Urechites andrieuxii (Apocynaceae), as 'raiz de la vibora', is used to treat nervous disturbances in Mexico, and the root has shown CNS-depressant activity (Jiu 1966).

Urmenentea tomentosa (Compositae), 'coca de los pobres', is chewed as a coca substitute [see **Erythroxylum**] in the Atacama Desert of Chile (Montgomery 1999), as is U. atacamensis ['coca del suri', 'coquilla'], which is also effective smoked, in a dose of 300mg (Rätsch 1998).

Vitex agnus-castus (Verbenaceae) ['chaste tree'] is sometimes used in Brazil as a type of 'jurema' [see **Mimosa**, **Pithecellobium**] (Ott 1997/1998, 1999), although originating from the Mediterranean region and w. Asia. The dried fruit has been chewed by monks to reduce sexual desire. It is now used to regulate irregular menstruation and treat premenstrual tension. Compounds found include the alkaloid viticine, the flavonoid casticin, the iridoids aucubin, agnoside and eurostoside, and an essential oil containing cineol (Bremness 1994; Chevallier 1996). V. negundo, 'indrasura' ['Indra's inebriating drink'], has been used as a Soma substitute, and is considered to be a form of 'amrita'; it contains flavonoids with antiadrogenous effects, and an essential oil (Müller-Ebeling et al. 2002; Rätsch 1998). See also *Methods of Ingestion*.

A Voyria sp. (Gentianaceae), as 'tuiruibanto', is used by the Machiguenga of e. Peru to treat headache, and the juice is used as eyedrops to sharpen the senses for hunting; the plant used to be added to Machiguenga ayahuasca brews [see **Banisteriopsis**] (Russo undated).

Werneria ciliolata and W. poposa (Compositae), 'akhana', are bitter herbs sometimes chewed with coca [see **Erythroxylum**] by the Aymara and Quechua of c. Andes (Antonil 1978). W. dactylophylla leaves are also reportedly used for the same purpose (Rätsch 1998).

Zea mays (Gramineae) [corn] flowers [not the same as cornflour!] were used by the Atzecs, as 'eloxóchitl', to relieve fatigue (Heffern 1974). The anther filaments [corn silk] are used as a 'kinnikinnick' smoking herb in N. America, and in Peru where they are claimed to have inebriating effects (Rätsch 1998). As reported in *Influencing Endogenous Chemistry*, sweet corn has been found to contain traces of *melatonin*, *tryptamine*, N-(p-coumaryl)-*tryptamine*, N-ferulyl-*tryptamine*, *tyramine* and desmethyl-*diazepam* (Ehmann 1974; Hattori et al. 1995; Schneider et al. 1972; Smith 1977a; Unseld et al. 1989).

ASIAN OBSCURITIES

Chinese and Indian medical traditions use a plethora of herbs for their tonic effect on the nervous and immune systems – they are often known to increase mental efficiency and enhance physiological harmony. As they are too numerous to cover fully in the main text, some are outlined here, as well as those other Asian herbs with more intoxicating effects, and uses of related species from elsewhere in the world.

Abies spectabilis (Pinaceae) ['talis patra'] and A. webbiana [A. densa; 'gobray salla', 'dunshing'] are fir trees used as incense by Nepalese shamans; the former species is regarded as a 'sister plant' to 'nigalo' bamboo [see Arundinaria above] (Müller-Ebeling et al. 2002). A. balsamea, A. bifolia and A. concolor contain piperidine alkaloids (Stermitz et al. 2000).

Abutilon indicum (Malvaceae), 'kanghi', is used in India for its leaves, which are aphrodisiac and sedative (Nadkarni 1976).

Acalypha indica (Euphorbiaceae), 'kuppu', is hypnotic, cathartic and emetic, and aerial parts are used in India to treat mania and hysteria (Nadkarni 1976). A. insulana [A. hellwigii] leaves are sometimes smoked in Papua New Guinea; leaves of A. hellwigii var. mollis have also been used as wrappers for smoking tobacco [see **Nicotiana**] (Thomas 2001a).

Aerva lanata (Amaranthaceae), or 'polpala', is used in Ayurveda as a flowering top decoction, which acts as a stimulant [in Sri Lanka, it was

drunk before tea (see **Camellia**) was introduced]. In Indonesia, it is considered a strengthening tonic (Bremness 1994).

Ailanthus altissima [A. glandulosa; A. peregrina] (Simaroubaceae), 'Tree of Heaven', is from China, though naturalised in Europe and the US. A Pennsylvanian herbarium note stated that the plant may be narcotic (Rätsch 1998). In TCM, the dried root bark or stem bark is known as 'chun pi', and is used as a haemostatic, and to treat diarrhoea, dysentery and other ailments. It produces an effect "very similar to that which occurs in beginning smokers while smoking tobacco" [see **Nicotiana**], and also acts as a muscle relaxant. Side effects can include nausea, vomiting and vertigo. The plant has yielded afzelin, amarolide, ailanthone (Huang 1993) and 5% ailanthin [quasiin] (Rätsch 1998), as well as [in roots] 1-carbomethoxy-β-carboline [also in leaves], 1-carbomethoxy-4-MeO-β-carboline, 1-carbamoyl-β-carboline, 1-aceto-4-MeO-β-carboline, 4-MeO-1-vinyl-β-carboline [dehydrocrenatine], 1-(2'-hydroxyethyl)-4-MeO-β-carboline, 1-(1',2'-dihydroxyethyl)-4-MeO-β-carboline, 1-(1-OH-2-MeO)ethyl-4-MeO-β-carboline, 1-carbomethoxy-4,8-dimethoxy-β-carboline [also in leaves] and 1-propionic acid β-carboline. A. malabarica bark and root have yielded 1-ethyl-β-carboline, 1-ethyl-4-MeO-β-carboline, 1-carbomethoxy-β-carboline, 1-carbamoyl-β-carboline, 1-aceto-4-MeO-β-carboline, 4-MeO-1-vinyl-β-carboline, 4,8-dimethoxy-1,2,3,4-tetrahydro-β-carboline [crenatidine] and 4,8-dimethoxy-1-vinyl-β-carboline [dehydrocrenatidine] (Ohmoto et al. 1981; Shulgin & Shulgin 1997; Souleles & Kokkalou 1989).

Alangium chinense (Cornaceae), 'bajiaofeng' in TCM, is a CNS depressant, muscle relaxant and anti-hypertensive, containing *anabasine* (Zhu et al. 1996a). The root of the Indian A. lamarckii is known to be a strong purgative and emetic, and has yielded an alkaloid, alangine. A. villosum is a paralytic poison in frogs, and A. salvifolium ssp. hexapetalum has shown hypotensive activity (Nadkarni 1976; Webb 1948).

Albizzia julibrissin and A. lebbeck (Leguminosae/Mimosaceae) are used for their dried bark in TCM, as 'ho-huan-pi' or 'he-huan-pi'; it is sweet and neutral, acting on heart, spleen, and lung meridians. It is said to enliven the spirit, relieve depression, control pain and invigorate circulation, and is used in doses of 9-30g to treat restless anxiety, insomnia, ulcers, carbuncles, muscle trauma and bone fracture, as well as showing stimulant, tonic, analgesic, anthelmintic, diuretic and oxytocic effects (Hsu et al. 1986). I have read reports of individuals smoking the bark for the same CNS effects. The rachillae, laminae and secondary pulvini of A. julibrissin yielded *serotonin* [0.0003, 0.00027 and 0.00047%, respectively] and *norepinephrine* [0.00034, 0.00028 and 0.00046%] (Applewhite 1973). Leaves have also yielded compounds responsible for closing [potassium-β-D-glucopyranosyl-11-OH-jasmonate] and opening [cis-p-coumaroylagmatine] the leaflets (Ueda & Yamamura 1999). Flowers of A. julibrissin have yielded quercitrin and isoquercitrin, flavonol glycosides with sedative activity (Kanga et al. 2000). The chloroform fraction of the ethanol extract of A. lebbeck leaf showed anticonvulsant [except for *strychnine*-induced convulsions], anxiogenic and CNS-depressant activity, as well as increasing brain levels of *GABA* and *serotonin*, and antagonising the effects of *amphetamine* in animals (Kasturea et al. 2000). A. lebbeck and some other A. spp. contain saponins known as 'sapotoxins', which can interfere with cellular respiration and weaken vital functions to the point of death (Davis 1988a). A. inopinata leaves yielded mixed alkaloids, which had CNS-depressant activity in mice [10mg/kg i.p.] (Assis et al. 2001). A. procera leaf [from a 3yr old seedling] tentatively tested positive for *5-methoxy-DMT*, along with two other compounds (Trout ed. 1997d); the whole plant also tested positive for HCN (Watt & Breyer-Brandwijk 1962). A. adinocephala leaves and stem bark yielded spermine alkaloids, budmunchiamines, which inhibited the malarial enzyme plasmepsin II (Ovenden et al. 2002). The Zulu use A. adianthifolia [A. gummifera] as a "love-charm emetic"; in some parts of w. Africa, the gum of the tree is used to ward off evil spirits (Watt & Breyer-Brandwijk 1962). In Jimi, Papua New Guinea, an Albizzia sp. is used in warrior rituals for fighting (Paijmans ed. 1976). In some parts of Africa, A. ferruginea stem bark is used as a homicidal poison (De Smet 1998), and in w. Africa the Efik used A. zygia bark as an ordeal poison (Davis 1988a). The Kalahari Bushmen may possibly use A. anthelmintica ['k ydi'] to aid in reaching a trance state for healing (Rätsch 1992), and it is used by the Masai [as 'ol mokotan'], mixed with food, as a stimulant-excitant. It is also known to act as an emetic and purgative. When consumed in large amounts [as it often is], it is said to cause "a form of berserk rage during which the warrior trembles from excitement and the saliva flows from the mouth" (Lehmann & Mihalyi 1982). In excess, it may reputedly be lethal (Davis 1988a); in small amounts, the bark is taken by Masai women as an aphrodisiac. In n. Rhodesia, beer made with the root of A. antunesia is also used as an aphrodisiac. A. versicolor roots have been used to make an arrow poison in e. Africa. In China, A. chinensis is used to stupefy fish (Watt & Breyer-Brandwijk 1962). See also A. lebbeck in *Methods of Ingestion*.

Alhagi pseudalhagi [A. camelorum; A. maurorum; A. persarum; A. pseudoalhagi; Hedysarum alhagi] (Leguminosae/Fabaceae), 'camelthorn', is a thorny plant originating in Asia, now widespread as a weed. It yields a sugary exudate known as 'manna' or 'Caspian manna', which is used medicinally in India and parts of the Middle East, and is reported to have aphrodisiac properties. The plant is also used in India to treat "certain brain affections". In the Concan, the plant is smoked mixed with **Datura**, **Nicotiana**, and Carum copticum seeds to treat asthma (Ghosal et al. 1974; Nadkarni 1976; Parsons & Cuthbertson 1992). The plant has yielded a variety of *phenethylamine* and tetrahydroisoquinoline alkaloids, as well as other compounds. The stems and roots contain essentially the same alkaloids, but the roots give a poorer yield – stems yielded *phenethylamine* [*PEA*; 0.00174%], N-methyl-*PEA* [0.00069%], *hordenine* [0.00036%], N-methyl-*mescaline* [0.00008%], N-methyl-*tyramine* [traces], coryneine [3,4-dimethoxy-N,N,N-trimethyl-*PEA*; 0.00017%], 4-OH-3-MeO-trimethylphenethylammonium and salsolidine [6,7-dimethoxy-1-methyl-THIQ; 0.0004%]; as well as 0.00215% *choline*, cholesterol, δ-7-avenasterol, ergost-5-en-3-ol, stigmast-5-en-ol, 24-ethylcholesta-5,22-dien-3-ol, 3-β-stigmasta-5,24-dien-3-ol and ursolic acid. The flavonoids catechin, epigallocatechin, leucodelphinidin and 3,3',4',5,5',7-hexahydroxyflavan were only found in the aerial parts (Ghosal & Srivastava 1973a; Ghosal et al. 1974; International... 1994).

Alisma plantago-aquatica (Alismaceae), 'ze xie', is used in TCM for its stems and tubers. It acts as a diuretic and is believed to "stimulate the female genitalia" (Keys 1976). It has been claimed that "taken for a long time, the eye and ear become acute, hunger is not felt, life is prolonged, the body becomes light, the complexion becomes radiant, and one can walk upon water [a reference to spiritual powers]" (Trout pers. comm., quoting Teeguarden).

Angelica sinensis (Umbelliferae), 'angelica', is called 'dang-gui' in TCM. The root is used to treat menstrual disorders, and is considered an excellent female tonic. It is also analgesic and sedative, as well as stimulating the immune system and improving muscle tone, strengthening the liver and improving circulation. It contains phytoestrogens, coumarins, essential oil and the sedative xanthotoxol – the latter has anti-AChE activity at low doses and anti-*acetylcholine* activity at high doses, as well as antiadrenergic, anti-*serotonin* and anti-*histamine* activities. Many Angelica spp. seem to have similar properties to A. sinensis (Chevallier 1996; Reid 1995; Sethi et al. 1992). A. polymorpha root essential oil contains *safrole* and *isosafrole*, and is also used in China as a sedative and analgesic [dose 5-10g] (Keys 1976). Angelica can be stupefying (Conrad 1988), and has been chewed as a narcotic in Lapland (Cooke 1860). The essential oil of A. archangelica is considered revitalising and restorative; it is stimulating in small quantities, and sedating in large quantities (Lawless 1994). Japanese angelica root, from A. acutiloba, has been shown to reverse *hyoscine*-induced performance deficits in rats (Ohta et al. 1993); *scopoletin* has been found in the plant (Buckingham et al. ed. 1994).

Aquilaria agallocha (Thymelaeaceae), 'Aloes wood', 'eaglewood' or 'calambat', is called 'chen hsiang' in TCM. Its heavy, resinous, fossilised root is tonic and stimulant, and treats nervous disorders [tension, exhaustion, neurosis etc.]. Burned as an incense in monasteries, its scent is calming and relaxing (Reid 1995). In Tibetan psychiatric medicine, it is used as an incense to dispel 'demonic spirits' (Clifford 1984). Kirati shamans in Nepal invoke it "with a mantra at the beginning of every shamanic session", and its aroma is used to bring one back from trance. Known there as 'agar' or 'agur pati', it is associated with Garuda, the shamanic bird spirit (Müller-Ebeling et al. 2002). Often, wood from other plants is sold falsely in place of A. agallocha (pers. obs.).

Aralia manshurica and A. shmidtii (Araliaceae) have been shown in Russian testing to have some **Panax**-like adaptogenic and stimulant properties; however, they appear to be more toxic than **Panax** and other well known tonic herbs. Their roots contain triterpenoid saponins which are glycosides of oleanolic acid, called aralosides. The LD50 of total aralosides from A. manshurica was 0.47g/kg in mice (Brekhman & Dardymov 1969b). A. nudicaulis, 'wild sarsaparilla', has been used in the US to treat coughs and as a stimulant and diaphoretic. It is sometimes used as a substitute for true sarsaparilla [see Smilax above]. Fruits of A. racemosa ['Indianroot'] are used in root beer (Brussell 2004).

Araucaria spp. (Coniferae), 'dangre salla', are used as incense by Nepalese shamans (Müller-Ebeling et al. 2002).

Asparagus lucidus (Liliaceae), 'tien men dung' in TCM, or 'shiny asparagus', is used for its roots, which when taken regularly act as a nutritive tonic, inducing a feeling of well-being and psychic sensitivity (Reid 1995; Trout pers. comm.). A. africanus leaves have been used as an ingredient of a snuff used in Malawi to induce trance [see above] (De Smet 1998).

Astragalus membranaceus (Leguminosae/Fabaceae), 'huang-chi' in TCM, is used for its root, which boosts the immune system, increases stamina, lowers blood pressure and increases protection from cold; it is also tonic to the lungs and spleen (Chevallier 1996; Reid 1995). In Sweden, A. baeticus has been used as a **Coffea** substitute (Von Bibra 1855). In Ladakh, India, goats have been known to die from eating too much A. tibetanus herbage (Bhattacharyya 1991). Some N. American Astragalus spp. are known as 'locoweeds', as they cause intoxication in stock animals, as well as cellular damage. Species recorded as locoweeds include A. argillophilus, A. bigelovii, A. earlei, A. hornii, A. lentiginosus, A. mollissimus, A. nothoxys, A. oocarpus, A. pattersonii, A. thurberi and A. wootonii. A Dr. Chestnut described the progressive symptoms of locoweed poisoning – "Two stages are recognised. The first, which may last

several months, is a period of hallucination or mania accompanied by defective eyesight, during which the animal may perform all sorts of antics. After acquiring a taste for the plant it refuses every other kind of food, and the second stage is ushered in. This is a lingering period of emaciation, characterised by sunken eyeballs, lusterless hair, and feeble movements. The animal dies as if from starvation, in periods ranging from a few months to one or two years." Some Astragalus spp. can accumulate toxic quantities of selenium, causing a poisoning unrelated to 'locoism' (Anon. 1888b; Kingsbury 1964; Oehme et al. 1968; Pammel 1911). A. miser has caused incoordination of hind legs, chronic paralysis and respiratory disturbances in cattle and sheep. The toxin responsible in this case is believed to be miserotoxin [3-nitro-1-propyl-β-D-glucopyranoside] (Keeler 1975). A. lentiginosus has yielded the toxic alkaloids swainsonine and swainsonine N-oxide [see **Swainsonia**] (Foster & Caras 1994; Keeler 1975; Molyneux & James 1982). Toxic amino acids such as selenocysteine and selenomethionine have also been found in some species (Culvenor 1970), and many species have been found to contain canavanine [see **Canavalia**] (Bell et al. 1978).

Avena sativa (Gramineae) fruits, 'wild oats', are said by some to be aphrodisiac, and act as a nerve, heart and thymus gland tonic. The decocted ripe plant may be used to treat depression, colds, excess cholesterol and menopausal oestrogen-deficiency. In Indian Ayurvedic medicine, they have been used as part of treatment for opiate addiction [see **Papaver**]. Also in India, A. fatua is used as a poison (Bremness 1994; Chevallier 1996; Emboden 1979a; Hutchens 1973; Nadkarni 1976). An alcohol extract of the plant was also shown to reduce tobacco cravings [see **Nicotiana**] in the majority of test subjects (Anand 1971).

Canna indica (Cannaceae) ['Indian shot', 'sabbajaya'] is used in India for its rhizome and fruit, which are credited with narcotic properties. The rhizome is also a diuretic, diaphoretic and demulcent, and is used to treat fever and dropsy. The seed is also stimulating and aids in healing wounds; the warmed juice is used as eardrops to relieve earaches. The rhizome is also boiled in rice-water with pepper [see **Piper 1**] and given to treat cattle who have eaten 'poisonous grass' (Nadkarni 1976).

Canscora decussata (Gentianaceae), 'shankhini', is used in India in the form of a paste of the whole plant taken with milk, as a nervine tonic; the fresh juice is given to treat insanity, epilepsy and nervous debility. Taken as a powder compounded with Saussurea lappa root [see below], Achyranthes aspera, Asparagus racemosus root, **Terminalia** chebula fruit, **Acorus** calamus and two other plants ['baberang' and 'gulancha'], for 3 days, it is said to "enable a student to learn by rote a thousand couplets of poetry" (Nadkarni 1976). The plant has yielded the xanthone *mangiferin*, which has weak MAOI effects (Bhattacharya et al. 1972), and the flavonoid diffutin, which is a mild CNS-depressant and anxiolytic (Harborne & Baxter ed. 1993).

Carlina biebersteinii (Compositae) was shown in Russian testing to have some **Panax**-like adaptogenic and stimulant properties; it has yielded 0.6-3.4% flavone glycosides (Brekhman & Dardymov 1969b).

Cedrus deodora (Pinaceae), 'Himalayan cedar' or 'deva daru' ['tree of the gods'], is used in ritual incense by Nepalese shamans (Müller-Ebeling et al. 2002). The Egyptians regarded C. libani ['tree of the Lord', 'cedar of Lebanon'] wood and oil as magical substances associated with Osiris, and used them in incense (Rätsch 1992). Aromatherapists use the essential oil to relieve "chronic anxiety" (Bremness 1994).

Celastrus paniculatus (Celastraceae), the 'black-oil tree' or 'intellect tree' of India, gives oils from its seeds – a deep-scarlet to yellow oil obtained by expression, and a black aromatic oil from distillation. The former is used externally for rheumatism, or burned, and the latter is a strong stimulant when taken as 10-15 drops, twice daily; it is also a strong diaphoretic. The seeds are considered to be aphrodisiac and brain tonic, increasing the intellect and memory; they also treat headache, asthma and some stomach disorders. The leaves and bark apparently share these actions. The leaf juice has been used to treat opium poisoning [see **Papaver**]. The seed oil has been shown to reduce turnover of *norepinephrine*, *dopamine* and *serotonin*, and reverse *hyoscine*-induced memory and performance deficits [in large oral doses in rats – 50-400mg/kg over 14 days]; it contains sesquiterpene polyol esters (Chopra et al. 1958, 1965; Gattu et al. 1997; Kirtikar & Basu 1980; Nadkarni 1976; Nalini et al. 1995; Perry & Metzger 1980; Tu et al. 1991). Bark from both aerial and subterranean parts of the related C. scandens of N. America ['false bittersweet'] are reputed to have 'narcotic' properties (Felter & Lloyd 1898).

Chrysanthemum morifolium [C. sinense] (Compositae) flowers ['ju hua'] are used in TCM in doses of 4-10g as a sedative, hypotensive, and refrigerant for influenza and headache; they are also applied as a poultice for tired eyes and skin disorders. The flowers contain an essential oil, stachydrine, *choline*, adenine, betaine, vitamin B1, sesquiterpene lactones, flavonoids [including *apigenin*] (Chevallier 1996; Keys 1976) and N-isobutyl-6-(2-thienyl)-2E,4E-hexadienamide, a compound with numbing properties (Shahata et al. 2001). Flowers of C. indicum were reputedly an ingredient of some Taoist 'elixirs of immortality' [see *Methods of Ingestion*] (Bremness 1994), and have been used in TCM as a digestive. As well as tannins and an essential oil, it contain 'chrysanthemine', a mixture of stachydrine and *choline* (Keys 1976).

Cistanche salsa (Orobanchaceae), or 'broomrape', is known as 'rou tsung rung' in TCM. The fleshy stem is used as an aphrodisiac – it enhances fertility in women, and in men increases sexual vitality and decreases involuntary ejaculation. It is considered an important tonic as it prevents semen loss [semen being thought to contain life essence, not an unwise assumption!] (Reid 1995).

Cleyera japonica var. wallichiana (Theaceae), 'chhasing', is used by Sherpas and others in Nepal as a stimulating tea-substitute [see **Camellia**]. Leaves are picked in late winter and prepared by boiling in water with wood ash [1 litre water and 200g ash for 1kg fresh leaves], cooling, washing with cold water, and sundrying before storing in a dry place for an extended period. For use a portion is boiled with water, milk and sugar for 10-15 minutes, then churned with a small amount of salt in a tall bamboo vessel before drinking. The taste and effects are reported to be practically identical to those of 'real' tea, yet no *caffeine* was detected in the herb. Other names for it are 'kalo bakalpate' and 'bhotechiya' (Chaudhary & Taylor 2004).

Clitoria terneata (Leguminosae), 'shankpushpi' [also many other beautiful names, such 'Vishnu-kranta'], is used in India for a wide variety of ailments; the root, bark, leaves and seeds are all used (Nadkarni 1976). More interesting is the Indian use of this herb as a brain tonic, to improve memory and intelligence. In rats, high oral doses of extracts from the root and aerial parts were shown to improve memory retention; this was believed to be due to an increase in brain *acetylcholine* levels, and AChE activity (Taranalli & Cheeramkuzhy 2000).

Cocculus lacunosus [C. populifolius; C. suberosus; Anarmita cocculus; Cissampelos cocculus; Menispermum cocculus and many other synonyms] (Menispermaceae), the 'cocculus bush' or 'kakmari' from India, bears toxic fruits sometimes known as 'crazy seeds' which were once added to beer to make it more intoxicating [see *Methods of Ingestion*]. In Indian medicine they are also regarded as emetic and are used to treat *morphine* poisoning. They contain the highly toxic CNS-excitant picrotoxin [1.5-5%; can cause delirium and coma] as well as aporphine- and berberine-type opiate alkaloids including menispermine (Harborne & Baxter ed. 1993; Nadkarni 1976; Rätsch 1998). C. leaeba and C. pendulus are also reputedly psychoactive (Schultes & Hofmann 1980). C. cordifolius [Tinospora cordifolia] root and stem, 'guduchi' or 'amrita', are used in India for a variety of ills and are known as a "potent vegetable tonic", acting as a rejuvenative, aphrodisiac and nöotropic. They contain berberine (Nadkarni 1976).

Codonopsis tangshen, C. pilosula and/or C. lanceolata (Campanulaceae), as 'dang-shen' or 'tang-sêng' [also sometimes called 'bastard ginseng'], are used in TCM as a cheaper substitute for ginseng [see **Panax**]; the root is used in a similar way to ginseng, though the effect is weaker and shorter-acting, requiring an average dose of 10-15g in decoction. It has an affinity for the spleen and lungs, and makes a useful asthma treatment. The root contains saponins, triterpene sterols, glycosides, resins, inulin and traces of alkaloids (Chevallier 1996; Hsu et al. 1986; Huang 1993; Reid 1995; Wong et al. 1983).

Coix lacryma-jobi (Gramineae) seeds ['Job's tears'] have many medicinal uses in Asia, and are considered tonic, sedative and cancer-preventative (Bremness 1994). The Lodha of w. Bengal add a paste of the roots of C. lacryma-jobi to their homemade liquor to increase its strength (Pal & Jain 1989).

Convallaria majalis (Liliaceae) ['lily of the valley'] roots and flowers have been snuffed in China to clear the head, restore speech and memory and "comfort the heart". It is potentially toxic (Bremness 1994).

Corydalis ambigua and C. soldida [C. yanhusuo] (Papaveraceae) rhizomes are used in TCM as 'yan hu suo' or 'yen hu suo', as a sedative, analgesic and antispasmodic. They contain opiate-type alkaloids such as corydaline [analgesic], corydine [irritant, adrenolytic, CNS depressant], l-tetrahydropalmatine [strong sedative, hypnotic, tranquilliser, analgesic; D1, D2 & D3 *dopamine*-receptor antagonist; blocks effects of *cocaine* in rats, and used in China as Rotundine to relieve cravings, withdrawal symptoms and relapse in human heroin addicts; depletes monoamines, particularly *dopamine*, but also *norepinephrine* and *serotonin*, as well as striatal *acetylcholine*], *protopine* and bulbocapnine [sedative narcotic, induces muscular rigidity]. C. bulbosa has also been used as a hypnotic and 'hallucinogen', and contains *protopine*. C. pallida whole plant has yielded d-tetrahydropalmatine, dl-tetrahydropalmatine, capaurine and capauridine. These and similar alkaloids are also to be found in other Papaveraceae not already mentioned, such as Bocconia, Dicentra, Dicranostigma, Fumaria, Glaucium [see below], Hunnemania, Hypecoum, Macleaya, Meconopsis and Stylophorum (Chevallier 1996; Keys 1976; Liu et al. 1982; Manske 1940; Mantsch et al. 2007; Marcenac et al. 1986; Onda & Takahashi 1988; Preininger 1975, 1986; Reid 1995; Szekely & Spiegel 1954). In Germany, Corydalis clava has been known as 'hexenscheiss' ['witch's shit'] (De Vries 1991).

Cryptomeria japonica (Taxodiaceae), 'dhupi salla', is used by shamans in Nepal as incense (Müller-Ebeling et al. 2002).

Cupressus tortulosa (Cupressaceae), 'Himalayan cypress', is known in Nepal as 'rai salla' and its heartwood is used by shamans as incense ['dhupi'] (Müller-Ebeling et al. 2002).

Cucumis trigonus (Cucurbitaceae), 'bitter gourd', fruit is mashed with milk, boiled, and applied externally in India to "prevent insanity, strengthen the memory and remove vertigo" (Nadkarni 1976).

Cucurbita maxima (Cucurbitaceae), 'red gourd', is used in India for various medicinal purposes; of most interest is the seed oil, which acts as a nervine tonic (Nasdkarni 1976). Seeds of this species and of C. pepo ['squash'] are considered aphrodisiac, and are used in tantric rituals (Rätsch 1990).

Curculigo ensifolia (Amaryllidaceae), 'hsien yu' in TCM, is also known as 'Brahmin ginseng' and was once imported from India. It is a nerve tonic, stimulant and aphrodisiac, and treats impotence and premature senility (Keys 1976; Reid 1995).

Cycas circinalis (Cycadaceae) male flower bracts are powdered and consumed in India as a narcotic, aphrodisiac and stimulant (Nadkarni 1976). In e. New Britain, the Tolai use the pollen as a narcotic. In Mabuiag, w. Torres Strait, sorcerers have been reported to eat young leaf shoots of an unidentified Cycas sp. ['budzamar'] "to become wild" (Thomas 2001a). Caution is advised, as Cycas spp. are generally considered highly toxic without adequate preparation. In Australia, indigenous peoples are known to use the seeds as food after extensive preparation to leach out the toxins, the exact process differing from region to region (Low 1989, 1991a). Cattle ingesting the leaves of some plants from the Cycadaceae have been known to suffer "neurological disorders[...]involving the irreversible paralysis of the hindquarters". Seeds and leaves of all Cycas spp. have been shown to contain the neurotoxin α-amino-β-methylaminopropionic acid; highest levels were found in C. circinalis and C. revoluta (Dossaji & Bell 1973).

Cynomorium coccineum (Orobanchaceae) is 'suo yang' in TCM; its root and stem treat premature ejaculation, and are tonic, aphrodisiac and promote semen production (Keys 1976; Reid 1995). The related 'thyme broomrape' [Orobanche alba] is a sedative and treats impotence (Bremness 1994).

Didymocarpus albicalyx (Gesneriaceae), 'kumkum pati', is used in ritual incense in Nepal; all parts may be used, though the root is the most potent (Müller-Ebeling et al. 2002).

Duchesnea indica (Rosaceae) is known as 'lyniang' in Meghalaya, n.e. India, where the root and lower stem are chewed as a betel nut substitute [see **Areca**] (Neogi et al. 1989).

Echinopanax elatum (Araliaceae) has been shown in Russian tests to have some **Panax**-like adaptogenic and stimulant properties, and is of similarly low toxicity (Brekhman & Dardymov 1969b).

Eclipta prostrata (Compositae) ['white eclipta'] is used in Ceylon as a general and brain tonic, said to change "a morbid state to one of health, without causing distress"; the roots are purgative and emetic. In Meghalaya, n.e. India, the leaves are used in the form of a paste mixed with mustard oil [see **Brassica**], rubbed on the forehead as a brain tonic and to relieve headaches (Neogi et al. 1989). Interestingly, the plant has yielded *nicotine* [as E. alba, though the synonymy of these two taxa is doubted by some], as well as a coumarin, wedelolactone (Lassak & McCarthy 1990; Nadkarni 1976; Pal & Narasimham 1943; Rimpler 1965).

Ephemerantha macraei [Dendrobium macraei; Flickingeria macraei] (Orchidaceae) tubers have been consumed by tantric magicians to enter a divinatory trance, as with **Vanda** (Rätsch 1992), and capsules also used as an aphrodisiac; it is one of the plants known as 'jivanti' in India and used as a strengthening, stimulant, demulcent tonic that treats "debility due to seminal loss". The plant contains an alkaloid, jibantine, as well as jibantic acids (Lawler 1984; Nadkarni 1976).

Epilobium angustifolium (Onagraceae) ['fire-weed', 'rose-bay willowherb'] juice, boiled down in water to form a sweet and thick 'liquor', is sometimes mixed with **Amanita** muscaria in Siberia. It is said to make the drink stronger. E. angustifolium is thought to be psychoactive (Brekhman & Sam 1967; Emboden 1979a; Saar 1991), and has shown tranquillising properties (Belozertsev 1966). The flowering tops, taken as a tea or vodka-based tincture, caused mild intoxication in one human (theobromus pers. comm. 2001). In Germany it has been associated with witches [known as 'hexenkraut'] (De Vries 1991). The related E. hirsutum is used to treat epilepsy in Morocco; eating the plant has caused cramps and coma (Watt 1967).

Epimedium sagittatum (Berberideae), or 'horny goatweed', is used in TCM for its leaf, 'yin yang huo'. It is an aphrodisiac in men, tonic, and a vasodilator. It strengthens the nerves and improves cerebral blood flow (Reid 1995). E. macranthum is also used as an aphrodisiac (Keys 1976).

Eucommia ulmoides (Eucommiaceae) is used in China [dose – 5-10g] for its tonic bark ['du zhong']; it has sedative, 'mental relaxant', aphrodisiac, analgesic and hypotensive effects. The bark exudes a latex that is known as 'gutta percha' (Keys 1976; Perry & Metzger 1980).

Euryale ferox (Nymphaeaceae), or 'foxnut', is called 'chien shih' in TCM. Its seeds are used to retard aging, and as a tonic nutrient to restore sexual potency and vigour in men, and are also analgesic (Keys 1976; Nadkarni 1976; Reid 1995).

Eurycoma longifolia (Simaroubaceae) root, 'pasakbumi' or 'tongkat ali', is used in Malaysia as a male aphrodisiac, reputed to increase virility and prowess. It is also used to treat dysentery, malaria, glandular swelling and other complaints. The root has been found to contain a variety of β-carboline and other alkaloids - canthin-6-one, 5-MeO-canthin-6-one, 9-MeO-canthin-6-one, 10-MeO-canthin-6-one, 4,5-dimethoxycanthin-6-one, 9,10-dimethoxycanthin-6-one, 8-OH-9-MeO-canthin-6-one, 9-OH-canthin-6-one, 5-OH-methylcanthin-6-one, 5-OH-methyl-9-MeO-canthin-6-one, 1-OH-9-MeO-canthin-6-one, 1-OH-canthin-6-one, canthin-6-one 3N-oxide, 9-MeO-canthin-6-one 3N-oxide, 9-OH-canthin-6-one 3N-oxide, canthin-6-one 9-O-β-glucopyranoside, β-carboline-1-propionic acid, 7-MeO-β-carboline-1-propionic acid, methyl-β-carboline-1-carboxylate, N-pentyl-β-carboline-1-propionate, eurycomanone [a quassinoid] and picrasidines L & Q (Kardono et al. 1991; Kuo et al. 2003). In n.e. Thailand, E. harmandiana ['ian don'] root is used as an aphrodisiac, bitter tonic, antimalarial and anticancer herb. It has yielded canthin-6-one, canthin-6-one N-oxide, 9-OH-canthin-6-one, 9-MeO-canthin-6-one, 9,10-dimethoxy-canthin-6-one, canthin-6-one 9-O-β-glucopyranoside, β-carboline 1-propionic acid, 7-OH-β-carboline 1-propionic acid and 7-MeO-β-carboline 1-propionic acid (Kanchanapoom et al. 2001).

Gastrodia elata (Orchidaceae) tuber is called 'tien ma' in TCM; it is sedative, anticonvulsant and stimulant to cerebral functions, and is used in doses of 5-10g as a tonic for myoneuralgia, vertigo, headache and rheumatism, and to expel toxins (Keys 1976; Reid 1995; Taguchi et al. 1981). It is believed to give "strength and virlity". Dried young stalks have also been used in TCM to treat headache and dizziness, and as an aphrodisiac longevity tonic. Roasted, steamed or raw, the tubers have also been eaten as food (Lawler 1984). An extract prolonged the effects of *hyoscine* in rats, and showed antioxidant properties. The tuber has yielded 0.146% 4-(β-D-glucopyranosyloxy)benzyl alcohol, 0.027% 4-OH-benzaldehyde [4-formylphenol], 0.021% 4-OH-benzyl alcohol, 0.0054% 4-OH-benzyl methyl ether, 0.041% parishin, 0.0026% gastrodioside, gastrodin, and several other related compounds (Taguchi et al. 1981; Wu, C.-R. et al. 1996). Of these, 4-OH-benzaldehyde inhibits *GABA* transaminase and the peroxidation of brain lipids (Haa et al. 2000). Vanillin has been reported from the tubers, but this needs confirmation (Lawler 1984).

Glaucium corniculatum (Papaveraceae) has sedative properties, and has been used to adulterate opium [see **Papaver**] in Iraq (Chakravarty 1976). The plant has been shown to contain many typical poppy-alkaloids, including allocryptopine, berberine, chelerythrine, coptisine, *protopine*, reticuline and sanguinarine (Preininger 1986).

Gordonia obtusa (Ternstroemiaceae) from India has leaves with stimulating properties similar to those of tea [see **Camellia**]; an alkaloid has been isolated, but not identified, and is said to be 'similar to *caffeine*' (Nadkarni 1976).

Gossypium indicum (Malvaceae) ['Indian cotton'] seeds are used in India for their nervine, aphrodisiac, expectorant, demulcent and laxative properties; they are also used to treat epilepsy. A syrup made from the flowers is said to be 'stimulating and exhilarating'. Seeds of G. herbaceum are also aphrodisiac (Nadkarni 1976), a property also attributed to the root bark. However in China, root bark is used to "inhibit the production of semen" (Rätsch 1990). G. hirsutum ['cotton'] fruits contain *serotonin* (Schneider et al. 1972). In the Ivory Coast of Africa, roots of Gossypium spp. are said to be used as a mild euphoriant and relaxant (Samorini 1995b).

Gynostemma pentaphyllum (Cucurbitaceae), 'Chinese sweet tea vine' or 'jiao gulan', is used in TCM as an energising immune stimulant (Bremness 1994).

Helminthostachys zeylanica (Ophioglossaceae) is known as an intoxicant and anodyne in India, but other details are scarce (Nadkarni 1976).

Hemerocallis lilioasphodelus (Liliaceae) ['daylily', 'hsuan ts'ao'] young leaves have been eaten in China to produce a mild intoxication that "allays sorrow". In larger amounts, they are claimed to be able to "heighten awareness and cause hallucinations" (Erhardt 1992; Wells 1997). The roots have yielded hemerocallin [stypandrol], a toxin which can cause mydriasis, blindness, paralysis, and lesions in the nervous system. This species, as well as H. altissima, H. esculenta, H. minor and H. thunbergii are considered toxic, and Hemerocallis spp. roots have caused human deaths in China. Hemerocallin is probably widespread in the genus, and has also been found in Dianella revoluta ['blue flax lily'] and Stypandra imbricata [the aptly-named 'blind grass'] (Wang et al. 1989). The related H. flava is used in Taiwan to treat insomnia and fever; it acts as a motor-depressant in animals, increasing the concentrations of 5-OH-indoleacetic acid and homovanillic acid in the brain stem, and vanilylmandelic acid in the cortex, as well as decreasing concentrations of *dopamine* and *serotonin* in the brain stem, and *norepinephrine* in the cortex (Hsieh et al. 1996).

Holarrhena pubescens [H. antidysenterica] (Apocynaceae), 'kurchi' or 'rainbow tree', is known as 'indrajow' in Nepal, and is considered a form of 'amrita' and is associated with Indra (Müller-Ebeling et al. 2002). The seeds are regarded as tonic and aphrodisiac in some Arab regions; the bark is a bitter anthelmintic and febrifuge, which is used to treat dysentery. Bark has yielded up to 1.2% alkaloids, and seeds 0.025%, consisting of kurchine and kurchicine, and possibly conessine and holarrhenine (Nadkarni 1976).

Kalopanax septemlobum (Araliaceae) has been shown in Russian tests to have some **Panax**-like adaptogenic properties, but is poorly studied;

the roots yielded saponin glycosides called, imaginatively, kalopanax-saponins (Brekhman & Dardymov 1969b).

Lagerstroemia flos-reginae (Lythraceae) of s.e. Asia has narcotic seeds; the bark and leaves are purgative, and the root is a stimulant, febrifuge and astringent. L. indica ['crepe myrtle'], a common horticultural plant, also has narcotic seeds; the bark is a stimulant and febrifuge, the leaves and flowers are purgative, and roots are astringent. L. speciosa seeds are also narcotic; leaves are purgative and diuretic (Burkill 1985-1997; Fong et al. 1972; Kirtikar & Basu 1980; Malone & Rother 1994; Nadkarni 1976; Watt 1967). L. indica contains alkaloids concentrated in the seeds and seed pods, with only traces in leaves and stems; mature seeds yielded 0.03-0.3% alkaloids, consisting of lagerstroemine [16%], lagerine [10%], decinine [2.8%], decamine [0.8%], dihydroverticillatine [0.5%] and decodine [traces] (Ferris et al. 1971). L. fauriei leaves from Tanegashima Isl. [Japan], harvested before flowering in June, yielded 0.013% *cryogenine* and 0.027% lythrine; leaves from a slightly different plant from the same place, designated as L. fauriei 'Tanegashima type', or L. subcostata var. fauriei, yielded 0.4% *cryogenine*, 0.2% lythrine and 0.04% lythridine. True L. subcostata leaves from Amamiohshima Isl. [Japan], harvested under the same conditions, yielded 0.0025% lasubine-I, 0.0029% lasubine-II, 0.0003% subcosine-I and 0.0025% subcosine-II (Fuji et al. 1978). See also **Heimia**.

Ligustrum japonicum (Oleaceae), 'Japanese wax privet', has berries called 'nu jen dze' in TCM. The activity is found in the seeds, which are tonic, nutrient and increase vitality. They prevent tumour formation and build immunity (Keys 1976; Reid 1995). L. lucidum, 'Chinese glossy privet', strengthens muscles and bones, aids clear vision and hearing, and treats insomnia (Bremness 1994).

Limmonium macrorhabdos (Plumbaginaceae) ['staspak'] is used as an intoxicant in Ladakh, India. The dried leaves are crushed, fried, then sun-dried for 7-8 days, before being powdered; this is mixed with water and put in a tightly corked bottle, and aged for a week before consumption. The nature of the effects was not made clear, but the drink ['staspakchek'] is reported to be dangerous in large doses (Navchoo & Buth 1990). L. vulgare has yielded *tyramine* (Smith 1977a).

Lycium chinense (Solanaceae) fruit, 'gou ji zi' or 'Chinese wolfberry', is used in TCM as a tonic and stimulant, also treating dimmed vision due to malnutrition. It 'lifts the spirits' and may be used to slow the aging process by promoting muscle growth and healthy hair and skin. The dried fruits are usually used, but sometimes the bark and leaf are also (Bremness 1994; Huang 1993). L. chinense has been shown to contain calystegine N1 [see **Convolvulus**] (Bekkouche et al. 2001). L. europaeum is used as an aphrodisiac in India (Nadkarni 1976). L. ferocissimum ['African box thorn'] has been suspected of causing a narcotic poisoning in both humans and pigs, and L. halimifolium and L. barbarum have been reported to have caused deaths in livestock (Webb 1948), though L. barbarum fruits are the edible 'Himalayan goji berries' currently popular as a nutritive health tonic (pers. obs.). In Germany, Lycium spp. have been known as 'hexenstrang' ['witch strand'] (De Vries 1991). Withanolides [see **Withania**] have been found in Lycium spp., and *hyoscine* has been found in L. barbarum (Rätsch 1998). L. chinense fruit has also yielded 9-formyl-*harman* and 1-carbomethoxy-β-carboline (Shulgin & Shulgin 1997).

Mangifera macrocarpa (Anacardiaceae) fruit from Indonesia acts as a hypnotic, and bark of M. odorata is used with other plants to treat hysteria and epilepsy; these trees are related to the mango, M. indica (Perry & Metzger 1980).

Marsilia minuta (Marsileaceae) stolons are decocted by Lodha women in w. Bengal, to treat insanity. The leaves are infused in cold water by the Santals as a soporific (Pal & Jain 1989). In s. Nigeria, M. quadrifolia ['water shamrock', 'akwa nmili'] is planted in gardens for protection; married couples take an extract as an aphrodisiac and to give fertility (Nwosu 2002).

Mesua ferrea (Guttiferae), 'ironwood tree' or 'mesua', is used in Indonesian medicine for its flowers, to treat mental disturbances. It is considered sacred, and is often grown near Buddhist temples (Bremness 1994). In Nepal, the fruit ['nagheshowr'] and wood ['rupkesari'] are used in ritual incense (Müller-Ebeling et al. 2002).

Mikania cordata (Compositae) leaves are used in India to treat itching and wounds; the root extract has strong narcotic and analgesic effects on mice (Rätsch 1998).

Morindae officinalis (Polygalaceae) root is called 'ba ji tien' in TCM; it is tonic, astringent, aphrodisiac, strengthens bone and sinew, and "increases willpower" (Reid 1995).

Nardostachys grandiflora (Valerianaceae), 'jata makhi', 'jatamansi' or 'jatamichi', is used in Nepal for its rhizome as an ingredient of 'bokshi dhup', an incense used to protect against witches (Müller-Ebeling et al. 2002).

Nitraria schoberi (Zygophyllaceae) is an Asian and Australian plant, of interest for containing tetramethylene-THβC (Pakhritdinov et al. 1971), *tryptamine* and *serotonin* in the aerial parts, as well as the new indole alkaloid nazlinin [which has serotonergic activity], and other alkaloids [nitramine, nitraramine, nitraroxine, nitraraine, dihydronitraraine, nitramidine, nitrarine, schoberine and schoberidine] (Üstünes & Özer 1991). N. komarovii has yielded 1-quinolin-8-yl-1,2,3,4-dihydro-β-carboline [komarovidine], 1-quinolin-8-yl-3,4-tetrahydro-β-carboline [komarovicine], 1-quinolin-8-yl-β-carboline [lomarovine], 1-quinolin-2-yl-β-carboline [nitramarine], 1-quinolin-5-yl-β-carboline [isokomarovine] and 1-quinolin-6-yl-β-carboline [komarovinine] (Shulgin & Shulgin 1997).

Panicum sarmentosum (Gramineae) roots are chewed as an aphrodisiac, with betel nut [see **Areca**], in the Malay Peninsula (Perry & Metzger 1980).

Pennisetum cenchroides (Gramineae) is said in India to pass on "a slightly intoxicating effect" to milk of buffalos that have eaten it [see also **Claviceps**] (Nadkarni 1976). In some parts of Africa, roots of P. spp. are used as a homicidal poison. Alkaloids have been detected in the genus (De Smet 1998).

Periplocea sepium (Asclepiadaceae) root bark ['gangli-upi', 'xiang jian pi', 'Chinese silk vine'] treats congestive heart failure and arthritis, also showing cholinergic, CNS and anti-inflammatory actions. Extracts of some species bind strongly to BZ receptors (Zhu et al. 1996a).

Physalis alkekengi var. franchetii (Solanaceae), 'suan-chiang' or 'suan-jiang', is used in TCM for its root, which "calms the mind, supplements ch'i, clears vision, dispels fever with irritability, and clears water". It contains 3-α-tigloyloxytropane, histonin and physalins A-C (Hsu et al. 1986); withanolides have been found in the genus (Rätsch 1998). The plant is also known as 'cape gooseberry' or 'winter cherry', and the ripe fruits are edible (Chevallier 1996). In Nigeria, P. angulata roots and leaves are said to be narcotic (Watt 1967). In the early convict days of Sydney, Australia, P. peruviana [another 'cape gooseberry'] leaves were used in brewing beer, to give bitterness (Low 1990). Fruits of P. minima produce HCN (Watt & Breyer-Brandwijk 1962).

Phytolacca acinosa (Phytolaccaceae) root, 'shang-lu', was decocted by ancient Taoists to 'see spirits' and treat intestinal worms. The root was associated with folk beliefs similar to those of 'mandrake' [see **Mandragora**]; sorcerers were said to carve the root into human form, which would divine the future. Reddish-purple roots are thought to be the psychoactive and toxic type – types with a white root [generally P. acinosa var. esculenta] are edible when cooked with several changes of water. The toxic types of the plant are known to be so poisonous as to be able to kill, and are used only externally for medicinal applications [for inflammation]. The ripe fruits have been used in the past to counteract sterility (Li 1978; Thompson 1968). Leaf and fruit have tested strongly positive for alkaloids (Webb 1949). P. americana [P. decandra], the 'pokeroot' of N. America, is known to be narcotic and toxic, causing "stupor, dullness, giddiness, and vertigo", and in overdose, death from respiratory paralysis (Emboden 1979a). In Tanganyika, P. dodecandra [P. abyssinica] is used as an epilepsy remedy. Most members of the genus are very toxic, and should not be ingested (Foster & Caras 1994; Watt 1967). Even when consumed after cooking with several changes of water, fatalities have occurred (Trout pers. comm.).

Picea smithiana [P. morinda] (Pinaceae), 'Himalayan spruce', is known as 'jhule salla' in Nepal, where shamans use it as incense (Müller-Ebeling et al. 2002). P. breweriana, P. omorika, P. pungens and P. sitchensis contain piperidine alkaloids; P. breweriana also contains pyrrolidine alkaloids (Stermitz et al. 2000).

Pinellia ternata (Araceae) tuber is called 'ban hsia' in TCM, and is sedative, cardiac sedative, antispasmodic, antitussive, antiemetic and expectorant; it is also used to "smooth the upward adverse flow of chi", and is an antidote to **Strychnos** poisoning. It is apparently toxic when fresh. It has yielded 0.002% *ephedrine* (Huang 1993; Keys 1976; Oshio et al. 1978; Reid 1995). P. pedatisecta, which is used to treat arrhythmia, has yielded *norharman* (Chin et al. 1981).

Podophyllum pleianthum (Berberidaceae) root ['k'uei-chiu'] was once taken in ancient China with **Cannabis** sativa fruit and **Acorus** gramineus rhizome to 'see spirits' [see **Cannabis** for further discussion] (Li 1978).

Polygonum multiflorum (Polygonaceae) root is known as 'he shou wu' in TCM. It is a mild sedative, as well as being a rejuvenative, nervine and blood tonic. It lowers cholesterol, counters infection, promotes fertility, and strengthens bone and sinew. Up to 3.7% lecithin has been found in the tubers (Chevallier 1996; Keys 1976; Reid 1995). P. hispidum has been used as a tobacco substitute [see **Nicotiana**] in S. America (Bailey 1880). In Meghalaya, n.e. India, P. hydropiper leaves and achenes are used as a fish poison (Neogi et al. 1989). P. punctatum ['korisowa'] and P. pennsylvanicum ['watonáka'] are used by the Tarahumara of n. Mexico to stupefy fish; they are known to cause contact dermatitis (Pennington 1958).

Poria cocos (Polyporaceae), a truffle sometimes known as 'Indian bread', is called 'fu ling' in TCM [younger, more desirable specimens are called 'fu shen']; it is a sedative, nervine, tranquilliser and stomachic, used to treat insomnia, schizophrenia, jaundice, palpitations, coughs and other complaints. It has some anti-cancer properties, enhancing immune response. Constituents include polysaccharides [pachyman, pachymaran] and organic acids [pachymic acid, pinicolic acid, eburicoic acid, tumulosic acid and 3β-hydroxylahosta-7,9(11),24-trien-21-oic acid] (Huang 1993; Huang et al. 1999; Keys 1976; Reid 1995).

Raponticum carthamoides (Compositae) has been shown in Russian

tests to have some **Panax**-like adaptogenic properties, and is of similarly low toxicity (Brekhman & Dardymov 1969b).

Rhodiola rosea (Crassulaceae), 'golden root' or 'rose root', is used in Siberia in an infusion to treat coughs and pain, yet if taken in excess it causes mild euphoria and a hangover. The root has been used in Scandinavia and n. Asia as a general and nerve tonic, and to give stamina and fertility; Vikings reputedly used it to increase their strength and endurance. Russian investigations showed the root to have **Panax**-like adaptogenic properties, and to be similarly non-toxic (Brekhman & Dardymov 1969b; Bremness 1994; Brown et al. 2002). As well as increasing blood-brain barrier penetration of *dopamine* and *serotonin* precursors, the root has been found to stimulate CNS effects of endogenous *norepinephrine*, *dopamine*, *serotonin* and *acetylcholine* [at nicotinic receptors]. The roots have yielded phenylpropanoids [rosin, rosarin and rosavin], flavonoids [rodiolin, rodionin, rodiosin, acetylrodalgin and tricin], phenylethanol derivatives [salidroside (rhodioloside) and tyrosol], monoterpenes [rosaridin and rosiridol], triterpenes [daucosterol and β-sitosterol] and phenolic acids [*chlorogenic acid*, hydroxycinnamic acid and gallic acid] (Brown et al. 2002). In China, R. sachalinensis ['red-spotted stonecrop', 'gao shan hong jing tian'] is "used for eliminating tiredness" (Huang et al. 1999).

Rotula aquatica [Ehretia viminea, Rhabdia viminea] (Boraginaceae) is known as 'kallur vanchi' in Kerala, India. Besides tropical Asia, it also occurs in Africa and Brazil, but has only been reported to be used as a psychotrope in Kerala. The Kani take it in small amounts in the morning as a euphoric stimulant, and in larger amounts in the evenings for enjoyment, relaxation, and to ensure a good sleep. For use, the leaves and tender stems are finely sliced, dried in the sun for 30min. [or in a pot over a fire], and mixed [by rubbing] with 'bidi' tobacco [see **Nicotiana**, **Datura**, Lyonia] in equal proportions. Sometimes, the sliced R. aquatica is stuffed into a hollow reed portion, which is then blocked up and the contents aged for 3 days. The slightly decayed herb is then removed and dried for use; the decay is reputed to strengthen the effects of the herb [see also **Aspergillus**]. After either initial preparation, the resulting mixture is rolled into cigarettes [c.8cm long, 0.75cm diam. at the lighting tip] containing c.3g R. aquatica and 3g bidi tobacco; sometimes a small amount of powdered tea [see **Camellia**] is added to enhance the effects. Bidi leaves, Ochlandra spp. leaves, or leaves from plants of the Marantaceae and Zingiberaceae, are used as wrappers for the cigarettes. Experienced users may feel the effects after smoking about half of a cigarette, though alcoholics or people with heavy **Cannabis** habits may require 2 in a row for the same level of satisfaction. Alternately, R. aquatica leaves and stems [c.10-15g] may be ground into a paste, mixed with coconut milk [c.100ml] and drunk. The initial stimulating effects soon give way to sedation and an urge to sleep, and smoking too much can result in vomiting; lime juice [see **Citrus**], buttermilk, or tamarind water may be drunk to reduce the effects if required (Nayar et al. 1999).

Sarcostemma brevistigma (Asclepiadaceae) is sometimes used in India as a 'Soma' substitute [see **Amanita**], and the milky sap has been said to be intoxicating and blood purifying. The dried stems are also used there as an emetic, being quite toxic. S. viminale has poisoned sheep, causing *strychnine*-like convulsions followed by paralysis. The latex has been used as a fish poison (Emboden 1979a; Tyler 1966; Watt 1967). In Sonora, Mexico, the Seri decoct S. cynanchoides as an external wash to relieve headaches. They may also drink a tea of the plant to treat 'black widow' spider bites [see below] (Felger & Moser 1974).

Saussurea lappa (Compositae), 'costus', is used in India for its medicinal root, which acts as an expectorant, aphrodisiac, tonic and narcotic [amongst other properties]. The powdered root has been smoked as an opium substitute [see **Papaver**], and in Nepal [as 'kuth'] it is used in ritual incense. It contains an alkaloid [saussurine], glucosides and an essential oil (Müller-Ebeling et al. 2002; Nadkarni 1976).

Schefflera arbicola, S. kwangsciensis and S. venulosa (Araliaceae) are used as 'qi ye lian' in China, and are sedative, hypnotic, analgesic, anticonvulsant, antispasmodic bronchodilators (Zhu et al. 1996a).

Securinega suffruticosa (Euphorbiaceae) leaves, flowers, and young branches are used in TCM as 'yi ye chau', to treat schizophrenia, depression, neurasthenia, neuralgia, paralysis and other complaints. It is mildly toxic due to its main active constituent, *securinine*, as well as the other related alkaloids found (Huang 1993). Roots have yielded 0.42% *securinine*, which is also found in the leaves (Mukherjee et al. 1963). S. virosa leaves have yielded 2-methyl-THβC (Shulgin & Shulgin 1997).

Shorea robusta (Dipterocarpaceae), 'Indian dammar', 'sal' or 'sakhewa', is used by Nepalese Kirati shamans for its bark resin ['salu pati'], or occasionally dried flowers, burned as a potently psychoactive incense for shamanic trance and travelling. However, it is used more often by witches, and shamans prefer to use it in blends with other substances. The leaves ['salkopat'] are sometimes used to roll 'bidi' cigarettes [see **Nicotiana**, and Lyonia above] (Müller-Ebeling et al. 2002). In Indian medicine the resin is said to have aphrodisiac, stimulant and astringent properties (Nadkarni 1976).

Spatholobus parviflorus (Leguminosae) might be the Nepalese 'debra lahara' or 'lache lahara' ['snaking/winding vine'], the roots of which are used by Kirati shamans for shamanic travel. After drying for 3-4 years, 1-3 "fingernail-sized pieces" of it are sufficient for a dose. It is preferably taken as an ingredient of 'bobkha' cakes, consisting of 5 parts lache lahara root, 5 parts rice, 5 parts **Piper** chaba root, 5 parts Bergenia ciliata seeds, 5 parts **Cannabis** flowers [including seeds] and 1 part **Datura** seeds. This is all ground and mixed, moistened with water, kneaded to a dough, and dried in the sun (Müller-Ebeling et al. 2002).

Stephania rotunda (Menispermaceae) roots are used in Vietnam as an effective opium substitute [see **Papaver**] (pers. comm.); they have yielded tetrahydropalmatine [see Corydalis above], stepharine, stepharotine and tuduranine (Tomita & Kozuka 1966; Tomita et al. 1966). In Japan, S. tetrandra is decocted to treat neuralgia and arthritis. In Bouganville, S. salomona leaves are rubbed on the skin to relieve pain (Perry & Metzger 1980).

Styrax tonkinense (Styraceae) yields a resin called 'benzoin' or 'an-hishsiang', which is burned as an incense to repel evil spirits and treat respiratory complaints. It may have been used by early Taoists in their 'elixirs of immortality' [see *Methods of Ingestion*]. A Mali shaman was reported to perform a ritual deep in the jungle, where benzoin was burned, and the shaman would make magical incantations to transform into a tiger and back again at will (Morton 1977; Rätsch 1992).

Thysanolaena maxima (Gramineae), 'tiger grass', is the 'amlisau' plant which, in myth, witches were tricked into eating by Shiva, to reduce the extent of their magical powers so they might be controlled. Nepalese shamans still believe it protects against witches, and it may be used to transform water into 'amrita' (Müller-Ebeling et al. 2002 [note: this work also erroneously refers to the plant as Thysandaena maxima]).

Toddalia aculeata (Rutaceae), 'kanchana', is an Indian plant known to have strong stimulant properties in all parts (Nadkarni 1976). In some parts of s.e. Africa, the ash of the plant is used against witchcraft (Watt & Breyer-Brandwijk 1962).

Trichopus zeylanicus (Trichopodaceae), 'arogyapacha', has fruits that are eaten by the Kani of Kerala, India, for instant stamina, better health and amelioration of old-age related disorders. The leaf extract was shown to be aphrodisiac in male mice; this property was destroyed by heating the extract in alcohol solution. The plant also has anti-ulcer, anti-fatigue, immunomodulating and anti-hepatotoxicity actions (Subramoniam et al. 1997).

Trigonella foenum-graeceum (Leguminosae/Fabaceae) ['fenugreek'] seeds have been a reputed aphrodisiac since ancient times; they act as a revitalising tonic, antipyretic, demulcent, anthelmintic, digestive, galactagogue and uterotonic. Seeds contain steroid saponins similar to those in **Dioscorea** [including *diosgenin*, yamogenin, gitogenin, tigogenin and neotigogenin] as well as flavonoids, and the alkaloids *choline* and trigonelline (Bremness 1994; Dawidar et al. 1973; International… 1994; Nadkarni 1976; Simonetti 1990).

Tsuga dumosa [T. brunoniana] (Pinaceae), 'thigre salla', is used by Nepalese shamans as incense (Müller-Ebeling et al. 2002).

An Usnea sp. (Usnaceae) [a lichen] is sometimes added to 'kava' [see **Piper 2**] in Pentecost, Vanuatu to cause excessive inebriation in a 'pretentious' kava-drinker (Lebot et al. 1992). Usnea spp. are often known as 'old man's beard', due to their shaggy appearance. In China, U. diffracta and U. longissima are known as 'Lao-tzu's beard', and are used after shade-drying to relieve dizziness, sweating, pain, cold and phlegm (Sharnoff undated, citing Strickmann, M. unpublished notes). A species growing on old wooden posts in central Victoria [Australia] was found to be psychotropic when smoked in small amounts, though I suspect regular use or high doses of this lichen would be toxic (pers. obs.). Chemicals found in various Usnea spp. include salazinic acid [possibly the same as usnaric acid], d-usnic acid, barbatic acid and other acids (Watt & Breyer-Brandwijk 1962).

Xanthium strumarium (Compositae), 'lokra', is used in Meghalaya, n.e. India; young leaves are edible, and fruits are "mildly narcotic" (Neogi et al. 1989).

FURTHER INTERESTING ESSENTIAL OILS AND AROMATIC HERBS

Phenylpropenes with psychoactive potential are widely distributed in essential oils. Some of the plants containing them, not mentioned elsewhere, are presented here:-

Myristicin is found in oils of Levisticum officinale seed ['Scotch lovage'; fresh root and herbage used as an aphrodisiac (Rätsch 1990)], Pastinaca sativa root ['parsnip'; also found in seed of cultivated, but not wild, varieties], Crithmum maritimum leaf, Ridolfia segetum flower, Phellandrium aquaticum leaf, Pseudorlaya miniscula and P. pumila seed, Oenanthe stolonifera fruit, seeds of O. aquatica, O. crocata, O. pimpinelloides and O. silaifolia (all Umbelliferae) (Harborne et al. 1969), and Orthodon spp. (Labiatae) (Weil 1965). Of these, Pastinaca sativa root also contains the boar pheromone 5α-androstenone (Claus & Hoppen 1979).

Elemicin is found in the oils of Aniba spp. (Annonaceae), Dalbergia spruceata (Leguminosae), Backhousia myrtifolia, Choricarpia leptopetala, Melaleuca bracteata, M. squamophloia [81% of essential oil in one chemotype] (Myrtaceae), Monopteryx uaucu (Leguminosae), Cleome

viscosa (Capparaceae) (Bock unpubl.; Harborne & Baxter ed. 1993; pers. comm.), Perilla citriodora (Labiatae) [17.8% of oil in one study] (Ito et al. 2000) and in Bridelia retusa (Euphorbiaceae) stem bark (Jayasinghe et al. 2003).

Asarones are found in the bark of Guatteria gaumeri (Annonaceae); it also contains asaraldehyde and a bisbenzylisoquinoline alkaloid, guattegaumerine [antitumour]; the genus is also rich in aporphine alkaloids (Dehaussy et al. 1983; Leboeuf et al. 1982; Leclercq et al. 1987; Lopez, J.A. et al. 1993). The Jamamadi of Brazil use G. cf. megalophylla as an ingredient of their arrow poison (Prance 1972). *Asarones* have also been found in Aniba hostmanniana (Annonaceae) and Caesulia axillaris (Compositae) (Buckingham et al. ed. 1994).

Anethole is found in the oils of Aster tartaricus (Compositae), Backhousia anisata, Clausenia anisata and Pelaea christophersenii (Rutaceae) (Harborne & Baxter ed. 1993).

Apiole is found in the oils of Crithmum maritimum root and seed, Levisticum officinale seed, Oenanthe aquatica, O. crocata, O. pimpinelloides and O. silaifolia seeds (Umbelliferae) (Harborne et al. 1969).

Dillapiole is found in the oils of Crithmum maritimum (Harborne & Baxter ed. 1993), Ligusticum scoticum fruit (Harborne et al. 1969), Bunium spp. seed, Heckeria umbellata, Oenanthe stolonifera (Buckingham et al. ed. 1994), Nothosmyrnium japonicum [76% of oil; also contains 18% nothoapiole (thought to be 2,3,6-trimethoxy-4,5-methylenedioxy-allylbenzene)] (Umbelliferae) (Saiki et al. 1970), Erigeron spp. (Compositae) and Orthodon formosanus (Labiatae) (Harborne & Baxter ed. 1993).

Estragole is found in the oils of Pinus spp. (Pinaceae), Agastache foenicula and A. rugosa (Umbelliferae), Solidago odora (Compositae), Dictamnus albus [see below] (Rutaceae) and Monopteryx spp. (Leguminosae) (Harborne & Baxter ed. 1993).

Eugenol is found in the oils of Origanum majorana (Labiatae), Achillea fragrantissima (Compositae), Rosa rugosa (Rosaceae) (Harborne & Baxter ed. 1993) and Litsea cubeba fruit (Lauraceae). As well as *safrole* [see below], L. cubeba essential oil [2-9% yield] is also rich in *citral*, and contains its isomer geranial, *citronellal*, α-*pinene* and numerous other components; it has antispasmodic and bronchodilatory activity (Tubtim & Wasiksiri 2007).

Methyleugenol is found in the oils of Dacrydium frankenii (Lauraceae) (Harborne & Baxter ed. 1993), Backhousia myrtifolia, Eucalyptus behriana, E. brassiana, E. globulus ssp. globulus, E. gomphocephala, Melaleuca bracteata (Bock unpubl.), M. leucadendra [74% from 0.1% essential oil; another sample contained none] (Myrtaceae) (Aboriginal Communities 1988), Lagorostrobus frankliuii ['Huon pine'] (Podocarpaceae) (Bock unpubl.), Prostanthera striatiflora (Labiatae) [0.4% of 0.2% essential oil] (Labiatae) (Aboriginal Communities 1988), Anemopsis californica (Saururaceae) [55.3% of root essential oil] (Acharya & Chaubal 1968) and Pinus sylvestris (Pinaceae) (Harborne & Baxter ed. 1993).

Methylisoeugenol is found in traces in Prostanthera striatiflora [0.02% of 0.2% essential oil] (Labiatae), and in Melaleuca leucadendra [22% of 0.1% essential oil; another sample yielded 0.06% from 0.9% essential oil] (Aboriginal Communities 1988).

Isosafrole is found in the oils of Ligusticum acutilobum and Murraya koenigii (Rutaceae) (Harborne & Baxter ed. 1993). Murraya exotica contains 3-formyl-indole; M. koenigii contains an array of indole alkaloids from the carbazole group, such as murrayazoline, murrayazolidine, exozoline and bicyclomahanimbine (Husson 1985).

Safrole is found in the oils of Aniba spp. (Annonaceae), Eucalyptus camaldulensis (Myrtaceae), Nemuaron humboldtii (Atherospermataceae) (Bock unpubl.; Harborne & Baxter ed. 1993), Litsea elliptica [leaf], L. cubeba [fruits] (Lauraceae) and Dryobalanops aromatica (Dipterocarpaceae) wood (Lakanavichian 2007; Tubtim & Wasiksiri 2007). D. aromatica, 'Borneo' or 'Sumatra *camphor*', also contains *borneol* and has been used to treat hysteria (Nadkarni 1976).

Bock (unpubl.) gives a good referenced overview of the occurrence of the above phenylpropenes in Australian plants.

Asaricin [sarisan] is found in Heteromorpha arborescens [H. trifoliata] leaves (Umbelliferae), along with falcarindiol (Villegas et al. 1988); the Zulu give a leaf-infusion as an enema, to treat abdominal disorders (Watt & Breyer-Brandwijk 1962).

Osmorrhizole and *isoosmorrhizole* seem to be uncommon; both occur in the rhizome essential oil [0.83% yield] of Osmorhiza aristata [Chaerophyllum aristatum] (Umbelliferae), 'xian gen qin', at 10-22% and 60-80% of oil respectively, as well as *anethole* [7%], *estragole* [1-3%], anisaldehyde, 2,4-dimethoxybenzaldehyde and a sterol. These compounds were previously incorrectly reported from Nothosmyrnium japonicum ('Japanese gao ben'), which does not contain them according to modern analysis, and it is presumed that O. aristata is the correct identity for the herbal drug 'Japanese gao ben', which is used in doses of 3-5g as a sedative, analgesic and antispasmodic (Keys 1976; Konoshima et al. 1967; Saiki et al. 1970). Root and rhizome of Ligusticum jeholense and/or L. sinense are used as 'Chinese gao ben' as a diaphoretic and to treat headaches and dermatitis; a claim of nothosmyrnol [*isoosmorrhizole*] in this drug (Huang 1993) may be due to confusion with O. aristata and N. japonicum (pers. obs.). L. sinense root essential oil contains 3-butylphthalide [26%], cnidilide [16%], *methyleugenol* [3%] and an unidentified 'compound X' [25%] (Saiki et al. 1970). *Osmorrhizole* has also been found in Anthriscus sp., Myrrhis sp. and Pinus spp. (Buckingham et al. ed. 1994).

Celery, Apium graveolens (Umbelliferae), has an essential oil in the seeds with CNS-depressant, tranquillising and anticonvulsant properties; alkaloids are also found in the seeds, contributing to the tranquillising effects (Nadkarni 1976; Rastogi & Mehrotra ed. 1990-1993). *Myristicin* has been found in the leaf, but not in the seed (Harborne et al. 1969). Celery root also has a reputation as an aphrodisiac (Rätsch 1990), and contains the boar pheromone 5α-androstenone [see Tuber spp. above] (Claus & Hoppen 1979). 'Geranium' oil [usually from 'rose geraniums', Pelargonium spp. (Geraniaceae) has some reputation as an aphrodisiac (Jalali-Heravi et al. 2006) and antidepressant (Bremness 1994), and although many people enjoy the aroma, I find it quite revolting! In recent years, 'geranium oil extracts' or 'geranamine' have made an appearance as legal party drugs and weight-loss/bodybuilding aids, often combined with other substances (pers. obs.). 'Geranamine' is a current marketing name for methylhexaneamine [2-amino-4-methylhexane; 1,3-dimethylamylamine], initially synthesised in the 1940's as an adrenergic drug (Budavari et al. ed. 1989). It has reportedly been isolated as a minor component of some P. graveolens essential oil [0.66% of the oil] (Zang et al. 1996), although I have not been able to verify this. Users say that c.25mg geranamine is sufficient for strong stimulant activity (pers. comms.). P. citronellum essential oil contains mainly geranic acid [36%], but also useful amounts of geranial [see *citral*] (Lalli et al. 2006). Melaleuca quinquenervia ['tea tree'] bears a potent essential oil, and bees feeding on the flower nectar have been observed to fall under an aggressive intoxication (Lassak & McCarthy 1990), the aggression perhaps caused by disorientation and the subsequent collisions between individual bees.

Besides the well-known catnip/catmint [see **Nepeta**], 'Chinese cat powder' [see **Actinidia**] and valerian [see **Valeriana**], there are also other cat-attracting plants, which might be psychoactive in humans. These include:-

Boschniakia rossica [growing parasitically on the roots of Alnus spp.] – contains boschniakine, boschnialactone and onikulactone; Menyanthes trifoliata ['bog myrtle'] – contains mitsugashiwalactone; Myoporum desertii – contains *nepetalactone*; Tecoma stans and T. radicans ['trumpet creeper'] – contain boschniakine, the former also containing *actinidine*, 4-nor-*actinidine* and other compounds; Nemophila menziesii ['baby blue-eyes']; Origanum dictamnus ['dittany of Crete']; Lippia javanica; Viburnum opulus ['cranberry bush'; see above]; and Teucrium marum ['cat thyme'] – contains dolicholactones C and D [most prominent in the essential oils of Sardinian plants] (Gross et al. 1972; Tucker & Tucker 1988). Some Teucrium spp. are toxic to the liver, and some also contain neo-clerodane diterpenoids [see **Salvia**]. Many members of the genus are commonly known as 'germander' (Chevallier 1996). T. argutum, 'native germander' from Queensland, Australia, has caused some interesting farmyard capers – "The roots are stated to cause a form of excitement in pigs, which rush madly about but recover after a short time" (Webb 1948). Regarding Boschniakia rossica mentioned above, it is known in China as 'bulaocal' and 'cao cong rong', and is used as a male sexual tonic (Huang et al. 1999).

Many members of the mint family, the Labiatae or Lamiaceae, have actions on the nervous sytem that have long been known to aromatherapists. These are now gaining more attention since the discovery of the neo-clerodane diterpenoid *salvinorin A* from **Salvia** divinorum. Similar diterpenoids have been found in other plants from the Labiatae, including members of the genera **Salvia**, **Scutellaria** and other relatives. It could be said the search is on for other diterpenoid compounds to compare to the tremendous effects of *salvinorin A*! Here we will briefly look at some of the well known Labiatae that have not been covered elsewhere in the book [bearing in mind that essential oils should generally not be consumed orally at risk of gastric irritation and liver toxicity].

'Bugle' [Ajuga reptans] – has been used as a mild narcotic; it is also analgesic when applied to bruises and small wounds (Bremness 1994). The related A. parviflora has been shown to contain new withanolides [see **Withania**], ajugins A & B (Khan et al. 1999a, 1999b), as well as neoclerodane diterpenoids (Beauchamp et al. 1996).

'Horehound' [Marrubium vulgare] – tea is sedative, muscle-relaxant, expectorant and antiseptic (Bremness 1994) – and is very bitter (pers. obs.)!

'Large-flowered calamint' [Calamintha grandiflora] – leaf tea is an invigorating tonic for "all afflictions of the brain", according to Culpeper. It contains *camphor*-like essential oil constituents (Bremness 1994).

'Lavender' [Lavandula spp.] – flower tea treats anxiety, dizziness, headaches and nausea. The essential oil is relaxing, mildly sedative and analgesic, and can treat insomnia and depression (Bremness 1994; Lawless 1994; Worwood 1995). The Indian L. stoechas is said to "strengthen brain powers, expel brain crudities and clarify the intellect" (Nadkarni 1976). In mice, a flower extract acted as a sedative, anticonvulsant and anti-

spasmodic; it appears to act as a calcium-channel blocker (Gilania et al. 2000).

'Lemon balm' [Melissa officinalis] – leaf tea is relaxing, sedative, and tonic. It soothes headaches, indigestion and nausea. The essential oil is anti-depressant, and narcotic and soporific in large doses (Bremness 1994; Conrad 1988; Lawless 1994; Worwood 1995). An extract of the herb bound to nicotinic- and muscarinic-*acetylcholine* receptors, displacing *hyoscine* (MacKenzie 2000; Wakea et al. 2000). See also *Producing Plant Drugs*.

'Patchouli' [Pogostemon cablin] – whole plant considered stimulant and antidepressant (Bremness 1994).

'Peppermint' [Mentha piperita] – inhalation of the essential oil vapours treats shock and nausea, while improving concentration. 'Mints' [Mentha spp.] can be stupefying in large doses (Bremness 1994; Conrad 1988; Lawless 1994). Hall (1973) mentioned a case in which a person "developed a toxic psychosis from addiction to mentholated cigarettes" [menthol is a major component of peppermint oil].

'Rosemary' [Rosmarinus officinalis] – essential oil of the flowering tops is invigorating and stimulates the CNS; it is said to act as a nerve tonic (Bremness 1994; Lawless 1994; Worwood 1995).

'Sweet marjoram' [Origanum majorana] – tea soothes nerves and relieves headaches (Bremness 1994). The essential oil is sedative, nervine, analgesic and comforting; it is stupefying in large doses (Lawless 1994). 'Oregano' [O. vulgare] can induce vertigo, stupefaction, trembling and obscured memory (Conrad 1988). In Germany, it has been known as a 'hexenkraut' ['witch herb'] (De Vries 1991).

'Thyme' [Thymus vulgaris] – essential oil of the leaves and flowering tops is a stimulant, nerve-tonic and antiseptic which strengthens the immune system and treats depression, colds and muscle pain (Bremness 1994). 'Wild thyme' [T. serphyllum] is sedative, and has been known in Germany as a 'hexenkraut' (De Vries 1991).

'Wood betony' [Stachys officinalis = Betonica officinalis; not to be confused with **Pedicularis**] – tea of aerial parts is a mild sedative and anxiolytic, being tonic to the nervous and circulatory systems. May be effective as a brain tonic (Bremness 1994). Has been used in brewing beer [see *Methods of Ingestion*] in Europe (Buhner 1998). Other Stachys spp. are also known to be psychoactive. S. arvensis ['stagger weed'] has caused stock intoxications in Australia; plants in seed are said to be more toxic (Everist 1974; Gardner & Bennetts 1956). S. tenuifolia is used by the Winnebago as a tea substitute [see **Camellia**] (Kindscher & Hurlburt 1998). In Africa, the Suto burn S. aethiopica var. glandulifera in the hut of a person who is delirious from fever, to exert a calming effect (Watt & Breyer-Brandwijk 1932). In Germany, S. annua has been known as a 'hexenkraut' (De Vries 1991). I have found the common horticultural plant 'lamb's ears' [S. byzantina = S. lanata] to be fairly stupefying and inebriating when smoked; the dried leaves are strongly aromatic when crushed. S. sylvatica leaf is also psychoactive when smoked (pers. obs.).

Incidentally, I have read of an experience from a man with a liver dysfunction, making him more easily affected by various chemicals [Claude Rifat (see http://dog.net.uk/claude)]. He consumed 20 drops of lavender essential oil [from Lavandula hybrida] combined with 20 drops of **Valeriana** officinalis essential oil, which after 40 minutes produced a cholinergic-like stimulation, combined with abstract simple hallucinations [experienced in darkness]. For those more tolerant to chemicals than Claude, the amount of essential oil that would need to be consumed to replicate this would presumably be toxic to the liver.

MORE β-CARBOLINES and MAO-INHIBITORS

There are many plants containing β-carboline alkaloids which have uncertain status as human MAOIs – such as *harman*, for example. Some of these plants are listed here in case future research shows them to be of value. An excellent overview of the β-carbolines is found in Shulgin & Shulgin (1997), which should be consulted for further listings [there's a lot!]. Unfortunately, references are not allocated to each listing. See also the section on Marine Life, below. Also added here are plants containing β-carbolines that have known human activity, but can only be mentioned briefly because I couldn't find enough information for a full entry, or the chemical information was found at the last minute.

Agropyrum repens (Gramineae), 'English couch grass' or 'twitch grass' – 6-OH-THβC 3-carboxylic acid, in roots and rhizomes (Shulgin & Shulgin 1997).

Apocynum cannabinum (Apocynaceae), 'dogbane' or 'Indian hemp' from N. America – *harmalol* in roots (Lutomski et al. 1968c) and cardioactive glycosides such as apocannoside (Trabert 1960; Turner & Szczawinski 1991). Toxic; root tea treats rheumatism, asthma, pox and whooping cough (Hamel & Chiltoskey 1975; Pendell 1995).

Arenaria kansuensis (Caryophyllaceae) – yielded *harmine* (Shulgin & Shulgin 1997), 1-acetyl-*norharman*, 1-acetyl-7-OH-*norharman* [arenarine D], 1-acetyl-7-MeO-*norharman* [arenarine C], 1-(2-MeO-1-OH-ethyl)-*norharman* [arenarine B], 1-MeO-methylcarbonyl-β-*norharman* [arenarine A] and 1-MeO-carbonyl-*norharman*. As 'xue ling zhi', the whole plant has been used in Chinese folk medicine to treat influenza, lung inflammation, jaundice and rheumatism (Wu et al. 1989). Known as 'sandwort', Arenaria spp. are smoked as a 'kinnikinnick' in N. America [see **Arctostaphylos**] (Siegel et al. 1977).

Calligonum minimum (Polygonaceae) – *harman*, *tetrahydroharman* [major alkaloid], *tetrahydroharman* N-oxide, *harman* N-oxide and calligonidine in all parts, as well as 2 unidentified alkaloids. Alkaloid content in roots was lowest during fruiting, but increased thereafter (Abdusamalov & Sadykov 1963; Abdusamalov et al. 1965).

Cayratia japonica (Vitaceae) has yielded flavonoids with MAOI activity in mouse brain; *apigenin*, luteolin and quercetin were most potent of these [strongest with MAO-A], with *apigenin*-7-O-β-D-glucuronopyranoside, luteolin-7-O-β-D-glucopyranoside, taxifolin [(+)-dihydroquercetin] and aromadendrin [(+)-dihydrokaempferol] being weaker (Han et al. 2007).

Chrysophyllum lacourtianum (Sapotaceae) – *norharman* and another β-carboline (Allen & Holmstedt 1980); the genus contains saponins and coumarins, and some are cyanogenic (Schultes & Raffauf 1990). C. prunifolium is a remedy for mental disease in Zambia (Watt 1967).

Cinchona succirubra (Rubiaceae) bark contains the alkaloids quinine, cinchonicinol and cinchonaminone, all of which inhibit MAO (Mitsui et al. 1989).

Commelina communis (Commelinaceae) – THβC [noreleagnine], *norharman*, *harman* and 1-carbomethoxy-*norharman* (Shulgin & Shulgin 1997).

Coriolus maximus (Agaricaceae) from West Indies, C. America and Old World tropics – *harman* (Allen & Holmstedt 1980). C. consors is an immune stimulant and antibiotic (Hobbs 1995). C. versicolor ['kawaratake', 'yun zhi'] is used medicinally in China and Japan, and contains polysaccharides [PSK and PSP] with potent antitumour properties (Willard & Jones 1990).

Cortinarius infractus [Phlegmacium infractus] (Agaricaceae) from Europe – novel β-carbolines infractine [*norharman* 1-propionic acid methyl ester], infractopicrine and 6-OH-infractine (Steglich et al. 1984). Many Cortinarius spp. are considered inedible or suspect; C. orellanus is poisonous, containing a polypeptide toxin [orellanine] which acts on the kidneys, and has an incubation period of 3-14 days or more. It has caused fatalities (Benedict 1972; Haard & Haard 1980). Some species, such as C. gentilis, can be very similar in appearance to some **Psilocybe** mushrooms, but for their lack of a bluing reaction (pers. obs.). Indeed, one case of a woman who obtained and consumed what she believed to be 'magic' mushrooms, suffering nausea, abdominal pain, flatulence, vomiting and diarrhoea for 5 days after [beginning 8hrs after consumption; no psychoactivity was reported], probably consumed a Cortinarius sp.; she suffered renal failure but recovered (Raff et al. 1992).

Cudrania tricuspidata (Moraceae), 'silkworm thorn', has yielded the isoflavones gancaonin A, alpinumisoflavone and 4'-O-methylalpinumisoflavone from its fruits; these compounds inhibited mouse brain MAO, with gancaonin A being selective for MAO-B (Han et al. 2005).

Cyathobasis fruticulosa [Girgensohnia fruticulosa] (Chenopodiaceae) from Turkey was found to contain 0.002% N-methyl-THβC, 0.0008% N-methyl-N-formyl-*tryptamine*, 0.004% *hordenine*, 0.0033% N-methyl-N-formyl-4-OH-β-*phenethylamine*, p-OH-benzaldehyde, p-aminobenzoic acid and p-MeO-benzoic acid in mixed roots and aerial parts (Bahçeevli et al. 2005).

Dictamnus albus (Rutaceae) aerial parts have yielded *skimmianine*, and four coumarins which acted as MAOIs in mouse brain [xanthotoxin, umbelliferone, auraptene and 7-(6'R-OH-3',7'-dimethyl-2'E,7'-octadienyloxy)coumarin] (Jeong et al. 2006).

Diospyros sp. (Ebenaceae) 'lemuni hitam' is a Malaysian medicinal plant which, though not known to contain β-carbolines, has shown MAOI-activity; the herb has yielded naphthoquinone/naphthalene compounds, including lemuninol A, which was the strongest MAOI in mouse liver, of the compounds tested (Okuyama et al. 1999). On Mabuiag, w. Torres Strait, a Diospyros sp. is chewed with unidentified plants by novices undergoing intitiation to become 'magicians' (Thomas 2001a). In some areas of s. Nigeria, a Diospyros sp. is used as a fish poison (De Smet 1998). Numerous species have edible fruits of varying degrees of desirability, such as 'Oriental persimmon' [D. kaki], 'American persimmon' [D. virginiana], 'Mexican persimmon' or 'zapote pieto' [D. texana], 'poor man's persimmon' or 'date plum' [D. lotus], 'mabolo' [D. discolor] and 'black sapote' [D. digyna] (Glowinski 1997). *Scopoletin* has been found in Diospyros spp. (Buckingham et al. ed. 1994).

Flindersia laevicarpa (Rutaceae) from n. Queensland, Australia – leaf yielded 0.035% *harmalan*, 0.035% acetyl-*harmalan*, 0.005% acetyl-*harmalan* dimer, 0.00096% of an unidentified *tryptamine*-derivative, 0.11% carpachromene, 0.73% flindersolide, 0.13% hesperidin and 0.0008% flindercarpin-2; bark yielded salicylic acid, hesperidin, lupeol, β-sitosterol, flindercarpins 1 & 2, nerolidol, (+)-threo-1,5-diphenylpentane-1,3-diol, flindersiachromone, 2,3-dihydro-flindersiachromone and 8-MeO-flindersiachromone; wood has yielded *skimmianine*, hesperidin, β-sitosterol and two alcohols (Picker et al. 1976). Many other species growing in

Queensland have tested positive for alkaloids, including F. acuminata, F. australis, F. bennettiana, F. bourjotiana, F. collina, F. oxleyana, F. pimenteliana and F. schottiana (Webb 1949).

Gentiana lutea (Gentianaceae) yielded 5-OH-flavanone, 2-MeO-3-(1,1'-dimethylallyl)-6a,10a-dihydrobenzo(1,2-c)chroman-6-one and 3,3"-(2'-OH-4-O-isoprenylchalcone)-(2"'-OH-4"-O-isoprenyldihydrochalcone), which inhibited MAO-B more than MAO-A (Haraguchi et al. 2004).

Gymnacanthera paniculata var. zippeliana (Myristicaceae) from Papua New Guinea – yielded 1,5-dimethoxy-3-(dimethylaminomethyl)-indole [1,5-dimethoxy-*gramine*] and N-methyl-THβC, as well as an unidentified *gramine*-like alkaloid [total 0.05-0.1% base alkaloids from leaves]. Orally in mice, the total base extract caused slight depression, moderate decrease in activity, slight mydriasis and hypothermia at 100mg/kg; twice this dose led to death. 100mg/kg [p.o.] produced analgesia in 30% of the mice (CSIRO 1990; Johns et al. 1967).

Hippophae rhamnoides (Elaeagnaceae), 'sea buckthorn' from Eurasia – *harman*, *harmol* and *harmalol* in whole plant [only *harmalol* in twigs and leaves] (Allen & Holmstedt 1980; Gill & Raszeja 1971; Lutomski et al. 1968c); *serotonin* in roots (Smith 1977b); and flavonoid glycosides in fruits (Hörhammer et al. 1966); leaves have also yielded quebrachitol (Plouvier 1951), astragalin and isorhamnetin (Rasputina et al. 1976). One alkaloid screening found no alkaloids in leaf, c.0.003% in bark and c.0.03% in root bark (Hultin & Torssell 1965). Berries used for skin eruptions, diarrhoea and dysentery; they are edible, but said to be poisonous in some locales (Bremness 1994; Chiej 1984; Kirtikar & Basu 1980).

Hypodematium squamuloso-pilosum (Hypodematiaceae), a fern from Asia and n. Africa, yielded 1-acetyl-β-carboline and 1-acetyl-8-OH-β-carboline (Zhou et al. 1998).

Lithospermum erythrorhizon (Boraginaceae) root has yielded the quinones shikonin, acetylshikonin and shikonofuran E, which inhibited mouse brain MAO (Choi et al. 2005).

Nauclea diderrichii [Sarcocephalus diderrichii; S. trillesii] (Rubiaceae), 'West African boxwood' – *harman*, 3-carbomethoxy-*harman* and 1-carbomethoxy-*norharman*; as well as pyridine alkaloids, an alkaloidal glycoside, quinovic glycoside-saponins and monoterpenoids in bark. In w. & c. Africa, the bark is decocted to treat stomach pain, fever and diarrhoea (Buckingham et al. ed. 1994; Lamidi et al. 1995; McLean & Murray 1970, 1971a, 1971b; Murray et al. 1971). In Congo, N. vanderguchii wood is macerated in water, and a glassful of the liquid drunk at morning and night to treat 'senile impotence' (Burkill 1985-1997).

Newbouldia laevis (Bignoniaceae) – *harman* (Allen & Holmstedt 1980).

Ophiorrhiza japonica [O. eyrei] (Rubiaceae), 'snakeroot herb' or 'shê kên ts'a' – yielded *harman*, 6-OH-*harman*, ophiorines A & B, lyalosidic acid and 10-OH-lyalosidic acid (Aimi et al. 1986). O. acuminata ['payang-payang gubat' ('mongoose plant')] leaves yielded *harman*, as well as lyalosidic acid and palicoside (Nonato et al. 1995). Leaves, stems and roots of the related O. mungos strongly inhibit the herpes virus (Tafur et al. 1976), and the root bark is sedative and laxative (Nadkarni 1976).

Oxalis tuberosa (Oxalidaceae), 'oca', is a tuberous food crop in the Andes – tuber found to secrete *harmine* and *harmaline* as major components [oddly, psychotropic effects are not known from this commonly-consumed plant] (Bais et al. 2002).

Pauridiantha callicarpoides (Rubiaceae) – *harman*, pauridianthine and pauridianthanine.

Pauridiantha dewevrei (Rubiaceae) – *harman*, cadambine and dihydrocadambine (Jacquesy & Levesque 1987; Levesque et al. 1983).

Pauridiantha hirtella (Rubiaceae) – leaves contain a small amount of alkaloids, with greater amount in the stem and root (Burkill 1985-1997).

Pauridiantha lyalli (Rubiaceae) – *harman* [16% of root bark alkaloids, 8% of trunk bark alkaloids and 5% of leaf alkaloids], pauridanthanol, pauridianthoside, lyaline, lyadine, lyalidine, OH-lyalidine, lyaloside and isopauridianthoside (Jacquesy & Levesque 1987; Levesque et al. 1983).

Pauridiantha viridiflora (Rubiaceae), this and the above Pauridiantha spp. all African plants – 0.08% *harman*, 0.007% pauridianthine, pauridianthinine, an anthraquinone and a glycoside from the bark (Burkill 1985-1997).

Polyalthia acuminata (Annonaceae) – contains dl-*tetrahydroharman* in leaf and bark, as well as 2-methyl-THβC [see **Tabernanthe**] (Shulgin & Shulgin 1997).

Rhazya stricta (Apocynaceae) is an Arabian shrub known as 'harmal' – it is abundant in alkaloids, and has varied medicinal uses. The whole plant, including the seed, is used to treat halitosis, chest pain, conjunctivitis, constipation, diabetes, fever, skin rash, intestinal worms, and as a galactogogue. The leaves and stems are burnt on a fire and the smoke inhaled to relieve chest pains, and the leaf juice is used for eyedrops. Overall, the plant is said to be sedative, antibacterial, antiinflammatory, and respiratory stimulant (Ali et al. 1998; Ghazanfar & Al-Sabadhi 1993). The seeds have been claimed to have yielded *harmine*, *harmaline* and *harmalol* (Ghazanfar & Al-Sabadhi 1993), though no reference was provided for this statement, and may have arisen through a colloquial confusion with **Peganum** harmala, which is also commonly known as 'harmal'. A large number of other alkaloids have been reported from the plant, most of them indole alkaloids – including *akuammidine*, vincadifformidine, (-)-quebrachamine, (+)-eburenine, rhazicine, rhazizine and (-)-nor-C-fluorocurarine (Buckingham et al. ed. 1994; Ganzinger & Hesse 1976). Leaves show sedative and antidepressant activity in animals, and have also been shown to inhibit MAO-A in rat brain, through increasing the activity of endogenous *tribulin*; low doses increased MAO-A activity, intermediate doses reduced it, and high doses had no effect. Low doses administered over 21 days decreased MAO-A activity, and increased MAO-B activity. Upon further investigation, it was noted that the butanol extract of the leaves decreased MAO-A inhibiting activity, whilst the weakly basic chloroform extract increased it (Ali et al. 1995, 1998, 1999).

Simira klugei, S. maxonii, S. mexicana, S. rubra, S. salvadorensis, S. tinctoria and S. williamsii (Rubiaceae) from C. and S. America – *harman* in barks (Shulgin & Shulgin 1997)

Symplocos racemosa (Symplocaceae), 'lodh tree' from n.e. India – 0.24% *harman* in bark [as 'loturine', thought to be a mix of *harman* and abrine], as well as 0.06% loturidine, 0.02% colloturine and quinovin (Allen & Holmstedt 1980; Nadkarni 1976); the plant also contains pelargonidin-glucosides (Rastogi & Mehrotra ed. 1990-1993). Some species contain salicylic acid, an analgesic aspirin precursor. Used in India as an aphrodisiac, astringent, antiinflammatory and emmenagogue (Kirtikar & Basu 1980).

MORE TRYPTAMINE ASSAYS

Thin Layer Chromatography [TLC] testing of various plants by well-known underground researcher 'Johnny Appleseed' and friends has [apart from those already mentioned elsewhere] revealed the tentative presence of psychedelic *tryptamine* alkaloids in hitherto unsuspected genera. Many of the results mentioned below still need confirmation using better techniques, and some might turn out to have been incorrect. Unfortunately, it seems that such research may not currently be published in mainstream science journals – however, such journals have recently reported the natural occurrence of several new *tryptamine*-derived alkaloids with unusual structures [see below]. New and familiar alkaloids of interest are showing up everywhere!

Bromus breviaristatus, B. sp. (Gramineae) – bands corresponding to *DMT*, sometimes some *5-methoxy-DMT* [*5-MeO-DMT*]. Only present in winter (Trout ed. 1997d; Trout pers. comm.). In published data, B. hordeaceus [B. mollis] and B. secalinus tested positive [c. 0.003%] for alkaloids (Hultin & Torssell 1965).

Dactylis glomerata (Gramineae), 'cock's foot' – tested positive for alkaloids [c.0.003%] (Hultin & Torssell 1965) and would be a good candidate for further investigation (Trout pers. comm.). It has been observed to support the endophytes Epichloë typhina [see **Festuca**] (Cabral et al. 1999) and **Claviceps** purpurea (pers. obs.).

Digitaria sanguinalis (Gramineae), 'crab grass' – strong band corresponding to *5-MeO-DMT*; only observed in hot summer (Trout ed. 1997d; Trout pers. comm.).

Elymus spp. (Gramineae), 'wild rye' – several species may contain *DMT* and *5-MeO-DMT*, pending further investigation (Trout ed. 1997d; Trout pers. comm.). Incidentally, E. canadensis has been observed to support an unidentified Epichloë sp. endophyte [see **Festuca**] (Cabral et al. 1999), and E. arenarius [Leymus arenarius] is known to host **Claviceps** purpurea (Alm 2003).

Gleditsia triacanthos [G. horrida] (Leguminosae), 'honey locust' – roots appeared to contain *DMT*, though the root harvest severely stressed the plant (Trout pers. comm.). Earlier formal studies found *tyramine*, N-methyl-*phenethylamine* and triacanthine in the leaves (International... 1994; Smith 1977a).

Hierochlöe odorata (Gramineae), 'sweet grass' – faint band corresponding to *DMT* (Trout ed. 1997d; Trout pers. comm.).

Leucoagaricus spp. (Agaricaceae) mushrooms, including the edible L. pudicus, are suspected of containing novel 6- or 7-substituted *tryptophan* or *tryptamine* derivatives, although these are probably not psychoactive (Stijve 2003; Stijve & de Meijer 1993).

Peristrophe hyssopifolia (Acanthaceae), which is similar in appearance to **Justicia** pectoralis – leaves tested faintly positive for *5-MeO-DMT* (Trout ed. 1997d; Trout pers. comm.).

Sorghum halapense (Poaceae), a.k.a. 'sorghum grass', 'Egyptian millet', 'aleppo grass', 'Johnson grass' – rhizome tested positive in varying strengths for *DMT*; most assays gave very weak results, though a late summer assay showed a very strong band corresponding to *DMT* (Trout ed. 1997d; Trout pers. comm.). This species and others also contain a cyanogenic glucoside called dhurrin, which is most prevalent after flushes of new growth, declining in concentration as the plant matures (Cheeke 1995; Lamp et al. 1990); *hordenine* has been found in S. vulgare (Lundstrom 1989).

Typha sp. (Typhaceae), 'cat tail' – tested positive for small amounts of *DMT*, along with many unidentified alkaloids (Trout pers. comm.).

Umbellularia californica (Lauraceae), 'California bay laurel' – yielded *bufotenine* (Shulgin & Shulgin 1997), though others state this to be *5-*

MeO-DMT instead (Rätsch 1998). Leaves contain an essential oil [containing 40-60% umbellulone] which can cause skin irritation, headache and even unconsciousness (Hall 1973).

Wisteria sp. (Leguminosae) – leaf and stem of an unidentified 3-4yr-old horticultural species tested strongly positive for *DMT*, as well as at least 4 other compounds (Trout ed. 1997d; Trout pers. comm.). Other Wisteria spp., such as W. brachybotrys and W. floribunda, contain flavonoids, terpenoids and terpenoid saponins [such as wistariasaponins, dehydrosoyasaponin in knots of the former species]; seeds and seedlings of the latter species have also yielded alkaloids, such as agmatine, spermine, spermidine, stizolamine, 1,5-pentanediamine, (3-aminopropoxy)guanidine, 1,4-butanediamine and 4,4'-diaminobutylamine (International… 1994; Konoshima et al. 1991); seeds of W. floribunda have also yielded 12.26% canavanine [see **Canavalia**] (Rosenthal 1977). W. sinensis seeds and pods contain a glycoside, wistarin [similar to *cytisine* in effect, but weaker], and a resin. These plant parts have poisoned children, with symptoms including "severe gastroenteritis with repeated vomiting, abdominal pain and diarrhoea, sometimes collapse". A brush-tailed rock-wallaby in captivity was poisoned by eating 1 large leaflet – 4-5hrs later, it became sleepy, and over the next 52 hrs its condition worsened until it was in a coma; 20hrs later, it was dead (Everist 1974; Picchioni 1965; Rätsch 1998).

The Australian shrub Hodgkinsonia frutescens (Rubiaceae) from Queensland contains a complex *tryptamine*-derived alkaloid [similar to those described under **Psychotria**] called hodgkinsine. Given orally to mice, 25-50mg/kg produced mild sedation and loss of balance; 100-500mg/kg also caused CNS depression, hypersensitivity to external stimuli, and vasodilation. Abundant indoles are also found in another Australian plant, Bleekaria coccinea [Excavatia coccinea] (Apocynaceae), which yielded *reserpine*, isoreserpiline and reserpiline from stem bark and leaf. Stem bark and wood also contain ellipticine and 9-MeO-ellipticine, which have antitumour activity (CSIRO 1990).

Lastly, stems and leaves of the New Caledonian plant Myrtopsis myrtoidea (Rutaceae) yielded 0.15% N-benzoyl-*tryptamine*, as well as 0.35% O-methyl-N-benzoyl-*tyramine*, 0.015% benzamide, 0.007% *skimmianine*, 0.005% γ-fagarine and 0.002% dictamnine (Hifnawy et al. 1977).

SOME OBSCURE FUNGAL NOTES

As the story goes… [according to Stephen Peele] In the late 1970's, an unidentified Lepiota sp., fruiting July to August in Florida, was claimed to be psychoactive by Peele, who named it after himself ['Lepiota peele']. He claimed to have encountered some mushroom pickers in a cow pasture who were picking this mushroom, claiming that they preferred its effects to those of **Psilocybe** cubensis. The mushroom was reported to grow on mats of 'Bermuda grass' [Cynodon spp. – see above] in pastures, forming from a dense mycelial layer; soil was reportedly pH 4-5.6, from morning urination by pasture cows. Substrate conditions were claimed to be very important for this species to be psychoactive. The fungi were also said to bruise 'beet red' to 'brown maroon'. Consumption of 3 'average-sized' specimens by Peele produced visual alterations [undulating black lines] and a feeling of lightness. A yellow liquid exuding from the mycelium was also reported to be psychoactive, as were dried mushrooms when smoked. Initial chemical screenings by Jeremy Bigwood were claimed to have revealed an unnamed active compound [unstable, with a shelf-life of 1-2 days], *ergine*, *DMT*, and many other compounds [later analysis by Stijve did not detect these alkaloids, nor a variety of other psychedelic alkaloids or known mushroom toxins; only *tryptophan* and urea were found]. Apparently work on this mushroom was mysteriously discontinued in the mid-1980's after Bigwood's lab was claimed to have been broken into and sabotaged, and the topic has been publicly ignored by major researchers in these fields (Peele 1993; Toro 2004). Unfortunately Jeremy Bigwood, a researcher of known repute, is now deceased, ruling out the possibility of seeking his comments on the matter (pers. comm.). Based on spores obtained from Peele's mail-order company, Peele's rudimentary description and photographs from a High Times article on the mushroom, it was later identified as probably being Lepiota humei ['Hume's Lepiota']. Fresh specimens of L. humei were then located in pastures "with a reputation for 'magic mushrooms'", tested numerous times for the presence of amatoxins [see below], and then consumed in a number of bioassays, increasing dosage each time. Even the largest doses consumed, 5-6 'robust specimens', produced no effects whatsoever (Akers 1992).

It should be noted that many Lepiota spp. are poisonous, and some have been shown to contain amatoxins [see **Amanita**] (Benedict 1972; Bresinsky & Besl 1989; Southcott 1974). Much care should be taken with identification. It should also be noted that most people with an opinion on the matter consider Peele's claims to have derived from questionable research, which some describe as 'fraudulent', others dismissing the entire story as an outright hoax (pers. comms.). We may never know the full story, but beware the rumour mill when it comes to ingesting potentially lethal substances!

Chlorophyllum molybdites [Lepiota morganii], the 'green-gilled parasol', has been reported from Africa to be psychoactive based on animal studies, and the Yoruba name for it, 'a jegba ariwo-orun' [roughly translated as "eat and see voices from heaven"]. In some areas it is commonly believed to be edible (Guzmán et al. 2000), but it also often causes poisoning, though some people appear to be immune. It is recorded as being toxic whether raw or cooked, though one person who had been eating it for years well-cooked experienced toxicity only after eating some raw. Symptoms are mainly gastrointestinal, with nausea, vomiting, abdominal pain, diarrhoea etc., though drowsiness and "neurologic dysfunction" have also been reported (Southcott 1996). It may be confused with the toxic Macrolepiota spp. (Bresinsky & Besl 1989). In Switzerland, Hydnum repandum ['hedgehog fungus'] is sometimes known to be intoxicating, although it is commonly held to be edible. In Japan, the genus Hydnum are known as 'yamabushi take' ['mushrooms of the mountain priests'] (Rätsch 1998). Another mushroom of the Hydnaceae, Sarcodon atroviridis, has been found to contain 4 *tryptamine*-derivatives which have so far not been identified (Wurst et al. 2002). S. imbricatum has been found to contain *tryptamine* and β-indoleacetic acid (Turowska et al. 1970). The European 'false chanterelle', Hygrophoropsis aurantiaca [Cantharellus aurantiacus], is "said to be edible but known to cause alarming symptoms [hallucination] in some cases" (Phillips 1981). One curious researcher ate 20 specimens without effect (Morgan 1995). Nothing is known of the chemistry of this species [see also **Hygrocybe** and **Hygrophorus**]. In India, the morel Morchella esculenta is considered an aphrodisiac and narcotic (Nadkarni 1976).

In Australia, Schizophyllum commune has been reported to be 'hallucinogenic' (Southcott 1974), though I have been unable to find the supporting reference for this claim. In s.e. Asia this species is sometimes consumed in soup as an edible fungus (Heim 1963b). Various strains of S. commune, as well as its culture medium, have yielded *isatin*, as well as other indoles indigotin [indigo], indirubin, schizocommunin and tryptanthrin as pigments (Epstein & Miles 1967; Hosoe et al. 1999).

Coprinus narcoticus, C. niveus and C. patouillardii have been included in lists of psychoactive mushrooms on the internet, though apart from general suggestions of a dosage in excess of 50 specimens, no further information is offered. C. narcoticus may have been included because of its suggestive specific name, though it appears that the species got its name from its 'strongly narcotic' odour, rather than from any knowledge of its pharmacology. I have no idea how the other two species came to be included on these lists. Some Coprinus spp. are known to cause non-psychoactive intoxication when consumed with alcohol (Bresinsky & Besl 1989). Heim tentatively included C. narcoticus as a psychotropic mushroom [under the classification "Mycétisme cérébral"] (Heim 1963b), though he gave no indication that this was due to anything other than the implications of its specific name. In Nepal, a Coprinus sp. known as 'gobre chyau' ['dung mushroom', a name also applied to Agaricus bisporus] is said by shamans to have mild psychoactivity, as are Omphalina aff. ericetorum ['kake chyau' ('crow mushroom')] and an Auricularia sp. ['shyamu' ('umbrella mushroom'), a name also applied to **Amanita** muscaria and mushrooms in general] (Müller-Ebeling et al. 2002).

C. atramentarius is reportedly used by some teenagers in s. Poland as a psychotrope. A dose of 30-50 fresh specimens [eaten] was reported to take effect within half an hour, resulting in visual and auditory hallucinations, dizziness, mydriasis and mumbled speech. The duration of effects was 2-5hrs (Kucharz et al. 1999). The mushroom has been shown to contain *tryptamine* [c.0.0027% in specimens from Rhode Island, US], *tryptophan* (Worthen et al. 1962), arginine, histidine, urocanic acid, imidazoleethanol, imidazolepropionic acid and *imidazole-4-acetic acid* (List & Reith 1961). Some researchers have reported finding tetraethylthiuram disulfide [disulfiram; Antabuse™, a chemical used in treating alcoholics [inhibits aldehyde hydrogenase in liver, which is involved in alcohol metabolism]; other researchers have failed to isolate this compound (Worthen et al. 1962).

One case of psychedelic intoxication attributed to C. comatus was presumed to have been a misidentification, based solely on the unexpected nature of the effects for this species (Toro 2004). C. comatus has been shown to contain *tryptamine* [c.0.006% in specimens from Rhode Island], *tryptophan* (Worthen et al. 1962), ergothionine, spermine, herzynine, *histamine*, dimethyl-*histamine*, *phenylalanine*, *tyramine*, *choline*, *aspartic acid*, *glutamic acid*, *glycine*, *methionine* and other amino acids (List 1959). C. micaceus has been shown to contain *tryptamine*, *tryptophan*, *phenethylamine*, isoamylamine, hypoxanthine, citrulline, ergothionine, *choline* and other amino acids (List & Hetzel 1960; Worthen et al. 1962).

Also, a word of caution regarding the genus Galerina – the toxicity of some members of this genus [and their similarity to some psychedelic species] has been mentioned elsewhere (eg. see **Psilocybe**; see also Benedict 1972). However one species, G. steglichii, was recently shown to yield 0.21-0.51% *psilocybin*, 0.08-0.21% *psilocin* and 0.02-0.07% *baeocystin* (Rätsch 1998). This warrants caution, due to the very likely possibility of confusion with deadly species – it is thus strongly suggested that searches for visionary Galerina spp. be discouraged for any but experts. Dangerous

temptation may also exist within the genus Clitocybe. Clitocybe gallinacea has been reported to contain unidentified lysergic acid-like alkaloids [see **Claviceps**, **Ipomoea**] (Heim 1963b); it has also been claimed to be 'narcotic' and to contain imidazole-derivatives (Norland 1976), though no information was given to support these latter assertions. C. gallinacea is often considered a variety of, or synonymous with, C. candicans. C. subilludens mycelial culture has yielded *ergonovine*, *ergotamine* and other ergot alkaloids [see **Claviceps**] (Foote et al. 1953), though later analysis of fruiting bodies did not observe these alkaloids (Tyler 1961). Specimens from Texas yielded 0.18% atromentin, a terphenylquinone with smooth muscle stimulant effects (Sullivan & Guess 1969). This compound was also found in the mycelium, along with thelephoric acid (Sullivan et al. 1971). C. clavipes is known to cause toxicity when consumed with alcohol, in a manner analogous to the disulfiram-like reactions well known with Coprinus spp. [see above] (Cochran & Cochran 1978). The phosphorescent Clitocybe illudens is known to cause intoxications, with symptoms including "violent gastro-intestinal disturbances with vomiting and diarrhoea, accompanied by great prostration." Deaths have not been reported in humans, and recovery is complete after a couple of days (Ford 1910/1911b). C. sudorifica [C. illudens var. sudorifica] is toxic to animals, and has muscarine-like actions (Ford et al. 1913). Muscarine [see **Amanita** for a brief discussion] is found in some related Clitocybe spp., even when very old, such as C. cerussata [0.012%], C. dealbata [0.01-0.18%], C. hydrogramma, C. illudens [0-0.0075%], C. infundibuliformis [C. gibba], C. rivulosa [0.035%] and C. vermicularis (Benedict 1972; Clark & Smith 1914; Genest et al. 1968; Stadelmann et al. 1976).

Dictyophora phalloides [D. indusiata], an obviously phallic mushroom with a 'challenging' texture, has been ritually consumed [as the 'male'] with **Psilocybe** mexicana [the 'female'] for divination in the Chinantec region of Oaxaca. No indication was given of its effect, if any. There must be a good reason, as this is not a mushroom you'd eat without one! Clavaria truncata [Clavariadelphus truncatus] and Gomphus floccosus [Neurophyllum floccosum] are used in similar ways. In Thailand, D. phalloides is obscurely used in sorcery, as well as for purposes of murder by poisoning. In Madagascar, the Tanala and Betsimisaraka also use it in sorcery, as they do with Lentinus tuber-reginum – again, details as to this use are scant. The related Phallus impudicus has been claimed to possess aphrodisiac properties – however, this may relate merely to the provocative form of the fungus. It has also been used in TCM as an analgesic for rheumatic pain (Guzmán 1990; Heim 1963b; Hobbs 1995; Ott 1993), and has yielded *imidazole-4-acetic acid* (Buckingham et al. ed. 1994), *phenethylamine* and *tyramine* (Smith 1977a). D. phalloides has yielded dictyophorins A & B [which stimulate nerve-growth factor (NGF) synthesis], and monoterpene alcohols (Ishiyama et al. 1999).

In Peru, the Lamista recognise a "yellow lichen-like fungus which grows on damp dead tree trunks", known as 'ampy-callampa'. It is associated with a snake, and singing its icaro is said to act against witchcraft, cure snake bites, and reveal treasures. The use of the fungus is said to be "very difficult" (Luna & Amaringo 1991).

The Fang Bwiti of Gabon are known to have used a mushroom known as 'duna', 'dune', 'kuna', 'difinyi' and/or 'lifunyi' in their iboga-related rites, although they now associate it with witchcraft. It is a large fungus which grows on withered trunks of Pycnanthus angolensis [see **Tabernanthe**] and Schyphocephalium ochocoa. Some Gabonese tribes use the dried, powdered mycelium in magic rites (Samorini 1993, 1997a). The Yoruba of Nigeria are very familiar with their local fungi, and many species have mythological associations. In contrast to the Fang, they regard mushrooms growing on living trees as being poisonous. Yoruba medicine men use Coprinus ephemerus in the preparation of some magical charms. Various Termitomyces spp., edible fungi which grow in contact with termite nests, are also used in preparing charms or offerings, along with other herbal ingredients, to procure good luck. T. robustus may also be roasted with Ceiba pentandra bark [see *Methods of Ingestion*] and Adansonia digitata bark, the mixture being eaten periodically for divination. Yoruba hunters also chew a mixture of T. globulus, Aframomum melegueta ['alligator pepper'; 7 seeds] and Phyllanthus floribundus leaf [see above]. The masticated mixture is rubbed on the bow and arrow, or gun, whilst making incantations. This is meant to make the game "drowsy and easy to kill" (Oso 1975, 1977).

Other anecdotal evidence [of doubtful validity] exists regarding the indigenous use of psychoactive fungi in the Ivory Coast. One, called 'tamu' [or 'the mushroom of knowledge'], was claimed to have effects reminiscent of *psilocybin* inebriation [see **Conocybe**]; the other, 'mushroom of action' [no traditional name given], was claimed to possess effects reminiscent of those of **Amanita** muscaria (Samorini 1995b). It has also been reported that 'mushroom churches' [also known as 'hand-clapping', 'hand-beating' or 'vision-seeking' churches] are widespread in parts of w. Africa (Walters 1995-1996). Further details about the actual involvement of fungi are not known to me.

The reader may be aware of the 5,300 year-old mummy found in a glacier in northern Europe, who has been named 'Ötzi'. He had two polypore mushrooms attached to him by a leather cord – one of these has been identified as either the 'birch-polypore' Piptoporus betulinus or the 'larch-polypore' Lacriformes officinalis [the former has known medicinal properties (Hobbs 1995), and has tested weakly positive for alkaloids (Spilsbury & Wilkinson 1961)], but the unidentified species [or identity not divulged] was surprisingly found to contain 'LSD-like' alkaloids, leading to speculation on a shamanic use for the fungus. Such speculations have been disapproved of officially, and results of further analysis [and even the detailed results of the initial analysis] have not been made public (Rätsch 1998; Stamets 1999).

It appears polypores may have a more extensive sacred usage than previously known. In N. America, the Blackfoot and Cree, amongst others, used Haploporus odorus for 'sacred purposes', and believed it to give 'spiritual power'. Besides its medicinal uses [as a styptic for wounds], it has been burned as a smudge or incense, giving off an anise-like scent [see **Illicium**, **Pimpinella**]. This may be done to purify an area before sacred rituals. One Cree healer said that it "opens the door to the spirit world and allows me to see and hear the spirits". Beads made from this polypore have been found decorating ceremonial robes, and within medicine bundles (Blanchette 1997). Also widespread is the indigenous use of Phellinus igniarius, growing on birch trees [Betula spp.], throughout N. America, north from the northern Plains region. This polypore was, and still is, burnt to ash and rolled into quids with powdered tobacco [see **Nicotiana**] for chewing, smoking or snuffing, to give a 'powerful kick'. The polypore has also been reported to have been smoked alone for its effects. Finely-crafted containers are often made to store the fungus ash. In the past, the identity of the fungus used has been incorrectly reported as Fomitopsis pinicola and **Ganoderma** applanatum (Blanchette 2001). Fomitopsis officinalis [Fomes officinalis] has a long history of medicinal use, for a wide variety of ailments. It may sometimes cause nausea and purging, as well as CNS-depression. In TCM, it is recommended that one not take more than 1g per day (Hobbs 1995). It is known as 'bread of ghosts' by some indigenous groups of the n.w. coast of N. America, and has been believed to be endowed with spiritual powers. The sporophores were carved into spirit figures, to act as guardians for the graves of shamans, or to facilitate healing ceremonies by acting as protective spirit totems. Unidentified polypores are reported to have "echo-making powers" by indigenous inhabitants of Vancouver Island [and the adjacent mainland]. "Some Ditidaht [Nitinaht] families who owned the right to tree fungus protective powers could use the fungus to reflect any evil or malicious thought directed towards members of the family back to the person who sent them" (Blanchette et al. 1992). Fomes pini has yielded *hordenine* (Smith 1977a).

Laetiporus sulphureus [Polyporus sulfureus; 'chicken mushroom', 'sulfur shelf'] is a mushroom usually considered edible in the US, though inedible in Britain, where some poisonings have occurred – causing nausea, abdominal pain and dizziness. In Canada, it has been recorded as causing a colourful psychedelic inebriation in a 6-year old girl. It is thought such a phenomenon may be an example of the great variability of individual response to various fungi and other foods (Appleton et al. 1988). It may be that psychoactive compounds derive from other smaller fungi growing on the fruiting body of the larger, more visible host. This may have been so in at least one other case of L. sulphureus poisoning, which was reported to have resulted in what were described as mild 'LSD-like' symptoms (http://www.bio.net/hypermail/MYCOLOGY/9805/0026.html). In Nepal, as 'kukhure chyau' or 'shakti chyau', it is sometimes used for shamanic travel (Müller-Ebeling et al. 2002). This species has been shown to contain *tyramine*, N-methyl-*tyramine*, *hordenine* [though one sample did not contain these alkaloids] (Lee et al. 1975), *phenethylamine*, isoamylamine, colamine, hypoxanthine, trigonelline, homarin, *choline*, *glutamic acid*, *glycine*, *methionine*, *phenylalanine*, alanine, adenine, arginine, asparagine, cystine, cysteine, histidine, leucine, lysine, proline, threonine, γ-butyrobetaine (List & Menssen 1959a, 1959b) and *imidazole-4-acetic acid* (Buckingham et al. ed. 1994). Another polypore, Meripilus giganteus, also contains *tyramine*, N-methyl-*tyramine* and *hordenine*, and has been known to cause "dizziness and disorientation" (Guzmán et al. 2000). In Nepal, a Polyporus sp. known as 'shakti chyau' is eaten by Sherpa shamans to obtain shamanic power (Müller-Ebeling et al. 2002).

Ustilago maydis [U. segetum], 'corn smut' or 'cuitlacoche', is a fungus parasitic on corn [Zea mays - see above], very similar in appearance to **Claviceps** gigantea, which also grows on corn [U. zeae is a similar species which also grows on corn]. The distasteful-looking sclerotium is eaten as a nutritious food in Mexico, and has been used traditionally by some N. American peoples in small doses as an abortifacient, uterine stimulant, and to stop post-partum bleeding. It has also been used in TCM as a tonic for the liver, stomach and intestines. Roughly a century ago, it was briefly used by westerners in N. America and Europe for the same purposes; its use was discontinued because although safer than **Claviceps**, its action was weaker and less reliable. On occasion, U. maydis has been noted to be a "cerebral stimulant, with attendant narcotic and hallucinogenic ef-

fects". Overdose can cause loss of hair, abortion, convulsions and sometimes death (Buhner 1998; Hobbs 1995). It seems probable that there is widespread variation in the alkaloid content of different strains. Earlier in the 20th century, researchers isolated alkaloids that appeared to be related to those found in ergot [see **Claviceps**] – ustilagine [stimulates uterine contractions and smooth-muscle; compared with ergotinine] and ustilagotoxin [compared to 'ergotoxin'], as well as 4 uncharacterised compounds, ustimaidines A-D (Heim 1963b). 6-MeO-benzoxazol-2-one has also been isolated (List 1960). In Yugoslavia, intoxications from consuming corn parasitised with this fungus have been observed in children, and dubbed 'infantile ustilaginism'. U. tritici has caused death in laboratory animals (Heim 1963b).

Mould fungi have been suggested to be responsible for a variety of unusual symptoms related to prolonged exposure to old books and musty, dank libraries. Headache is most commonly reported, though inhalation of the spores of some moulds could possibly induce 'hallucinations' or other psychotropic activity, with sufficient chronic exposure. In a whimsical and simplistic summation, mycologist R.J. Hay wrote that "the source of inspiration for many great literary figures may have been nothing more than a quick sniff of the bouquet of mouldy books" (Hay 1995). Of course, inhalation of mould spores is, in general, a very risky practice that can lead to serious health problems (eg. see Etzel 2002, and **Aspergillus**). Psychotropic moulds have also been suggested as a possible causal factor behind the perceptive phenomenology of 'haunted houses' (Goodman 1995; de Rivaz 1995).

Recently, health concerns have arisen in the US related to widespread mould growth in water-damaged buildings [often using poor quality building materials]. The mould most commonly found in these situations has been Stachybotrys chartarum [S. atra]; it produces trichothecene toxins [including satratoxin, trichodermol and trichodermin], as well as phenylspirodrimanes and stachybotrylactones. The trichothecenes and the phenylspirodrimanes suppress immune function, amongst other things. Symptoms of inhalation include chronic fatigue, cough, sore throat, tightness in the chest, nose bleeding, dyspnoea and mild fever. It is suspected of having caused pulmonary haemorrhage in infants. Memnoniella echinata has also been found growing in these situations, sometimes with S. chartarum; it has been found to produce the trichothecenes trichodermol and trichodermin, as well as griseofulvins (Etzel 2002; Jarvis et al. 1995, 1996; Johanning et al. 1996).

One biochemist, William Sherwood, experienced unusual mental alterations after exposure to a treated extract of the mould Neurospora crassa. A substance isolated from the mycelium, dubbed 'BGE' [thought to be β-OH-pseudo-*tryptophan*], had been cyclised by exposure to an acid, to form an eseroline compound, which when heated with a base emitted fumes which were accidentally inhaled on several occasions. Sherwood described his experiences – "The first symptom which I mentioned of inhaling the fumes was a sudden, severe headache. This lasted but a short time and was followed by a feeling of deep remoteness. I began to walk aimlessly. I did not speak. Sometimes I merely sat and stared at my laboratory notes. The simplest physical manipulations became impossibly difficult. I thought the same thought over and over, repeatedly. I felt unable to communicate with others. When forced to speak to others, including members of my own family, I felt anger or hostility. When I did speak, I felt that another person, whom I called to myself, 'the Outside Talker', was speaking, rather than I. I never felt that anything was wrong with me, but that I was different from all others. I could not recognize that anything was wrong with me – but others, of course, did. My wife finally concluded that I was, upon these occasions – and each episode lasted for several days – insane, and she blamed it directly on my work at the laboratory." Later he found that the intoxication could be reversed by taking 100mg of Frenquel, a piperidyl drug (Sherwood 1957). A mutant strain of this species, N. crassa '47904', has been found to accumulate *2-dimethylaminoethanol* (Honegger & Honegger 1959).

It is interesting to note that chloroform, an inebriating volatile solvent, may be produced by some fungi and released into soil air. Species shown to achieve this biosynthesis include Agaricus arvensis, a Bjerkandera sp., Caldariomyces fumago, **Mycena** metata, Peniophora pseudopini and Phellinus pini (Hoekstra et al. 1998). Rickenella straminea, a mushroom related to the genera **Mycena** and Gerronema [see **Mycena**], has been found to contain 0.1% *5-hydroxytryptophan* (Stijve & de Meijer 1993).

BEES, WASPS and SPIDERS

Interestingly, honey bees [Apis mellifera] contain some psychoactive chemicals in their stings. By dry weight, honey bee venom contains 0.13-1% *dopamine*, 0.1-0.7% *norepinephrine* [NE], 0.6-1.6% *histamine*, 0.8-1% *GABA*, 0.02% β-aminoisobutyric acid, 1% adolapin [analgesic] and 3% *apamin*. Other peptides are also found – 40-50% melittin, 1.4% procamines A & B, and others in lesser amounts. Enzymes are present, such as 1% acid phosphomonoesterase, 1.5-2% hyaluronidase, 1% lysophospholipase, 10-12% phospholipase A2 and 0.6% α-glucosidase. Glucose [0.7%] and fructose [0.9%] are also present. *Dopamine* levels rise rapidly to a maximum in 20-25 day-old bees; *NE* is highest in 40 day-old bees (Pick 1984; Shipolini 1984).

A close friend of mine recalled an incident where he had taken some LSD in a Botanical Garden, and part way through the trip he stepped on a bee [he was barefoot] which stung the sole of his foot. As well as experiencing the pain from the sting and its venom, he was surprised to notice his trip greatly potentiated at the same time (Gutterson pers. comm.)! I can only presume this was due to the injection of the compounds discussed above, synergising with the already present effects of the LSD in the nervous sytem of my friend. Others have claimed reaching a "kind of hallucinatory mild delirious state" from bee stings. Some people have been experimenting with 'apitherapy' [intentional stinging by honey bees for therapeutic purposes] to treat arthritis and other complaints – reported effects include analgesia and feelings of well-being (pers. comms.).

Bees, of course, can not be ignored for their honey! Besides the intoxicating honeys that can be produced by the concentration of plant toxins from the pollen and nectar that are collected by the bee (see Ott 1998a; Palmer-Jones 1965), honey has a mild 'narcotic' action (Nadkarni 1976), and is highly nutritious and medicinal when unfiltered and unheated. The medicinal virtues vary depending on the predominant plant species from which the honey is derived, though those demonstrated so far include immunostimulant, antibiotic, antiviral, antiallergenic, antiinflammatory, antianaemic, expectorant, laxative and tonic properties. And, of course, honey may be made into mead, as it has been for thousands of years [see *Methods of Ingestion*] (Buhner 1998). Honey, 'royal jelly' and bee pollen are reputedly aphrodisiac (Rätsch 1990).

Neurotransmitter-substances are also found in wasp and hornet venoms [Vespideae]; wasp venoms may contain varying amounts of *serotonin*, *histamine*, *epinephrine*, *NE* and lesser amounts of *tyramine* and *dopamine*; hornet venoms may contain large amounts of *acetylcholine* (Nakajima 1984; Welsh & Batty 1963). The larvae and nests of the hornet Polistes mandarinus, and ashes of Vespa spp. wasp nests, are reputedly aphrodisiac (Rätsch 1990).

To the Tachi Yokut of s. California, the 'black widow' spider [Latrodectus spp.] is known as 'métsa' ['true, real, big, and powerful'], the same name they give to their shamans. They regard Black Widow as "the supreme dream helper of powerful shamans" (Groark 1996), though they have not been reported to ingest black widow venom in any way. Some spider venoms have potential for psychoactivity, though their use is definitely a risky, even desperate venture! The venoms generally are neurotoxic, causing extreme excitation in the central and peripheral nervous sytems. The most notable example is Latrodectus venom, which causes an explosive release of *acetylcholine* from cholinergic neurons, followed by a depolarisation blockage of all nicotinic receptors. Physiological effects include extreme pain, muscle spasms, profuse sweating, extreme nervousness and anxiety, the feeling of 'going mad', cell necrosis, and injuries of the liver, kidneys, spleen, lymph nodes, thymus and adrenals. Death can result from respiratory paralysis. Venom from L. mactans has been shown to stimulate the release of met-*enkephalin*-like substances in in vitro rat tissue. Other spiders bearing such neurotoxic venoms include Theraphosa spp. [so-called 'tarantula'], Phoneutria spp., Trechona spp., Atrax spp. ['funnel-web spiders'], and Harpactirella spp. (Bucherl 1971b; Geren & Odell 1984; Janicki & Habermann 1983; Kruk & Pycock 1983). *Serotonin* is found in the venoms of Acanthoscurria spp., Lasiodora spp., Lycosa spp., Pamphobeteus spp., Pterinopelma spp. and Phoneutria spp. (Welsh & Batty 1963). The 'Sydney funnel-web' spider, Atrax robustus, yields interesting chemicals from its venom – the female secretes traces of *5-methoxytryptamine*, and the male secretes *serotonin*; both venoms also contained *tyramine*, octopamine, spermine, spermidine, *glycine*, glycerol, *GABA*, glucose, citric acid, lactic acid, phosphoric acid and urea, as well as the potent atraxotoxin. The female secretes more venom, though the male is more toxic (Duffield et al. 1979; Geren & Odell 1984).

Of some dubious interest is the phenomenon of 'tarantism' or 'tarantismo', originating and primarily observed in Taranto, Apulia, s. Italy, and said to be related to venomous bites from 'tarantulas'; however, in this region all poisonous or scary-looking spiders are regarded as kinds of tarantula [American tarantulas are different again]. Tarantism occurs in summer each year [when the spider venom is believed to be most toxic], affecting many people who may or may not have actually been bitten by a spider. They may appear stupefied or manic, or complain of a variety of symptoms; as quickly as possible, musicians and a crowd gather, as the musicians play melodies known as 'tarantellas' which build to a frenzy [tarantellas are also formalised folk tunes accompanied by courtship dances, and have also appeared in ballet and classical music; these originated in Naples and are unrelated to the phenomenon discussed here]. The music incites the 'bitten' person/s to dance excitedly until collapsing, and later the process repeats. The dancing is thought to help affect a cure by moving the poison out of the system, although once bitten, tarantism may recur each following year without a further bite; other treatments, including bloodletting, have been recorded for the condition, though dancing to this specific kind of music is the primary method. As interesting

all of this sounds, it has fairly been explained as a case of culturally-specific mass hysteria rather than being actually due to spider bites [at least in the majority of cases - sometimes necrosis at the site of the bite is reported alongside other symptoms, suggesting that sometimes a real spider bite is involved]. It is likely that the phenomenon arose as a continuation of similar dances associated with the cults of Bacchus and Cybole, established prior to Christian rulers taking control of the region, which was once part of the Greek empire; in this way, villagers could continue their practices under the guise of curing tarantula bite [or scorpion bite, which was believed to result in the same effects and require the same treatment]. Others believe it to be due to heatstroke and drinking too much wine in the sun [this is the hottest region of Italy], although it would be odd to encourage dancing in order to cure heatstroke. Regarding the identity of spiders believed to be involved in real or imagined cases of spider bite, the 'wolf spider' Lycosa tarantula was said to be the main spider responsible, although it is now known to have a fairly harmless bite. The 'malmignatle', Latrodectus tredecimguttatus [L. mactans tredecimguttatus; 'Mediterranean black widow'], is probably the actual culprit if there is one (Russell 1979); its venom contains α-latrotoxin [LD50 in mice (s.c.) - 0.02μg/g], which stimulates *norepinephrine*, *dopamine* and *GABA* release and depletes *acetylcholine* (Geren & Odell 1984). A S. American tarantula, Psalmopoeus cambridgei, has yielded the peptide psalmotoxin 1, which has potent analgesic activity linked to indirect activation of *enkephalin* pathways (Mazzuca et al. 2007).

Many years ago I received a report of an individual of an experimental nature who smoked 'red-back spider' venom [Latrodectus hasselti; L. mactans hasselti], resulting in temporary paralysis and an altered state of consciousness reminiscent of an anti-cholinergic syndrome [eg. see **Datura**] (pers. comm.). Remarkably, or ridiculously, some people claim to have smoked spider webs for psychotropic effects, if Time magazine can be taken seriously – "given a receptive state of mind, it is possible to turn on with practically anything – or virtually nothing. Witness the fact that some undergraduates, dissatisfied with mellow yellow [see **Musa**], are already beginning to tout the high potentiality of yet another new ingredient: spider webs" (Moore 1967).

GIANT CENTIPEDES, MILLIPEDES and SCORPIONS

Centipedes of the genus Scolopendra are capable of inflicting venomous bites on humans, which act partly on the CNS, and also cause toxic effects. Symptoms include great mental anxiety, dizziness, vomiting, irregular pulse, headache, local pain and inflammation. S. viridicornis venom acts powerfully on the nervous system, stimulating glands with smooth muscle, accelerating respiration, and causing loss of equilibrium, sweating and vomiting; death may sometimes occur following convulsions and respiratory paralysis (Bucherl 1971a). This symptomology is similar to that induced by cholinergic neurotoxins found in spider and cobra venoms [see above, and **Naja**]. The biting apparatus have yielded 0.00087% *serotonin*, though the venom itself would contain much higher concentrations (Welsh & Batty 1963).

S. subspinipes ssp. multidens is used in TCM as 'wu-kung' [also 'tien-lung' or 'pai chiao']; it is considered pungent, warm and poisonous, acting on the liver meridian. The dried, powdered body is given in doses of 1-2.5g to treat convulsions, tetanus and snakebite; it is antispasmodic and antibacterial, as well as contributing some hypotensive activity. The centipede contains c.70% protein substances, and two toxic substances with histaminergic and haemolytic activity (Hsu et al. 1986). *Histamine* itself has also been found in the venom of S. subspinipes and S. oraniensis ssp. institania (Numata & Ibuka 1987). A Scolopendra sp. taken in wine is reportedly an aphrodisiac (Rätsch 1990). In Thailand, unidentified species of giant centipede are sometimes soaked in 'mekong whiskey', and the tincture drunk as an aphrodisiac; it is also reputed to have toxic properties (pers. comm.).

Madagascan brown lemurs [Eulemur fulvus] have been observed using unspecified millipede species as a probable psychotrope and medicament. The lemurs will take a single millipede, place it in the mouth, and bite it gently, prior to rolling it across the skin and fur for apparent antiparasitic and insect-repelling properties. Presumably from absorption of millipede toxins through the mouth, the lemurs display "an expression of blissful pleasure" for c.20 minutes. "As it applies its medication, the lemur drools copiously and its eyes glaze over." In S. America, 'wedge-capped capuchin' monkeys [Cebus olivaceus] use millipedes in the same manner, with the additional detail that "up to four capuchins may share a millipede, passing it around like a marijuana cigarette" (Downer 2002). 'Owl monkeys' [Aotus trivirgatus] have also been observed in captivity [in Florida] using millipedes in a similar way, biting them and then rubbing the insects on the fur of their backs. The monkeys were observed to writhe around in apparent excited bliss; with milder intoxications, "their eyes glaze over and they're completely focused on what they're doing". In this latter case, the millipedes were identified as Anadenobolus monilicornis, possibly accidentally imported on plants or fruit from the West Indies or S. America (Ovalle 2002).

Some millipedes secrete their deterrent toxins as droplets from granular pores when harassed. Such secretions may be irritating [such as the pyrrolidine alkaloid polyzonimine from Polyzonium rosalbum] (Numata & Ibuka 1987) or cause 'burning' and lesions when brought into contact with the skin or eyes [such as with secretions from Polyconoceras spp. (Salpidobolus spp.)] (Hudson & Parsons 1997; Radford 1975). Other secretions may simply repel predators due to an offensive odour, such as those from Ommatiulus sabulosus, which contain toluquinone, and repel mice. Toluquinone has been found to decrease the pain threshold in mice (Capone et al. 2002). Buzonium crassipes secretes chemicals which repel ants, including β-*pinene* [35%], limonene [6%] and the alkaloid buzonamine [59%] (Wood et al. 2000); this is also the case with Eucondylodesmus elegans, which secretes (1E)- and (1Z)-2-nitroethylenebenzenes (Kuwahara et al. 2002). Some millipedes, such as Floridobolus penneri, secrete benzoquinone derivatives (Attygalle et al. 1993), and some [such as Glomeris marginata] secrete piperidine alkaloids such as glomerin and homoglomerin (Numata & Ibuka 1987).

Unidentified scorpions were recently reported to be used as a psychotrope by heroin addicts in Quetta, Pakistan. One user reported sun-drying the tail stings, before grinding and smoking them – he further remarked that "when I smoke scorpion, then the heroin is like nothing to me" (Reuters 2001)! Scorpion venom itself can be dried to a greyish powder, which remains potent for years if stored in refrigeration. Scorpions were often represented on monuments of the ancient Egyptians, and were also prominently depicted on monuments relating to the mystery cult of Mithras in n. Africa (Balozet 1971). One company has even begun marketing 'Scorpion Mezcal' [see Agave spp. and 'pulqué' in *Methods of Ingestion*], with an unidentified scorpion in each bottle, but the sting has been removed and thus the scorpion probably does not impart any psychotropic activity to the beverage (http://www.scorpionmezcal.com/mezcals/faq.shtml).

The dried, processed whole body of the Korean and Manchurian scorpion Buthus martensis is used in TCM as 'chuan-hsieh' or 'quan-xie'; the tail used alone is called 'hsieh-hsiao'. It is considered pungent, neutral and slightly poisonous, acting on the liver meridian. In doses of 1.2-6g, it treats convulsions, tetanus, hemiplegia, venomous bites, and controls pain. It has a weaker antispasmodic effect than the centipede, and is antifungal, nervine and strongly sedative, also causing vasodilation and inhibiting *epinephrine* release. B. martensis contains cholesterol, stearic acid, palmitic acid, lecithin, trimethylamine, betaine, *taurine*, buthoic acid and katsutoxin [buthotoxin], which has similar action to the neurotoxins in snake venom [see **Naja**] (Hsu et al. 1986; Keys 1976). Its venom is highly toxic. The haemolytic activity of its venom is in contrast to most other scorpions, stings of which do not cause haemolysis (Balozet 1971). B. tamulus [Mesobuthus tamulus concanensis] has caused frequent poisonings in India resulting from its sting – symptoms include restlessness, agitation, fear, hyperexcitability, disorientation, pain, hypertension, hyperthermia, tachycardia, pulmonary oedema and sometimes convulsions. The venom has shown anxiogenic activity in rats, as well as inhibiting MAO by *tribulin* activity; it appears to have a marked action on cholinergic and adrenergic receptors, and an indirect action on bradykinin, as well as increasing peripheral angiotensin levels (Bhattacharya 1995).

Wild scorpions generally produce more venom than captive ones. Scorpion venom consists mostly of proteins, and generally loses toxicity when treated with ammonia or iodine. Its toxicity is located primarily in the water-soluble fraction. Scorpion venoms are generally neurotoxic, with stings causing severe local pain [followed by a prickling sensation and then desensitisation], agitation, increased muscle tone with contractions, suppressed reflexes, crying, salivation, perspiration, mydriasis, impaired vision, arrhythmia, impaired respiration, hyperglycaemia, feelings of anguish, and sometimes fainting, vomiting and diarrhoea. In severe cases death may result from respiratory paralysis. Sometimes, there may be a relapse of symptoms after an apparent recovery. Even handling scorpions or inhaling the air over their enclosures can result in spasmodic sneezing. Venoms of many scorpion species, such as Buthotus minax, Centruroides gracilis, Leiurus quinquestriatus, Opisthocanthus cavaporum, Parabuthus hunteri, Tityus bahiensis, T. serrulatus, T. triniatus, T. trivittatus and Vejovis spinigerus, contain *serotonin*, which is responsible for causing the local pain of a scorpion sting but is not otherwise thought to contribute to the intoxication (Balozet 1971; Numata & Ibuka 1987; Welsh & Batty 1963). One person noted marked stimulation and mood-enhancement after being stung by a scorpion of the genus Centruroides the night before (C.S.C. 2002).

ANTS and ASSORTED 'BUGS'

There have been several reports of Californian 'Indians' ritually ingesting unidentified large, red ants for their psychoactive effects. Young men amongst native American groups in s. California, who are usually acquainted with **Datura** and **Nicotiana** as their main shamanic plants [Kitanemuk, Kawaiisu, Tubatulabal, Northern Miwok, Yawelmani, Wikchamni, Yawdanchi, Bokninwad, Yokod, Palewyami and Hokan-

speaking Chumash groups], sometimes ritually consume ants in vision quests to gain 'dream helpers'. These ants are actually regarded as being more powerful than **Datura** as a shamanic ally, and consuming them is a matter of individual choice, rather than an enforced initiation procedure. Different groups differ in the details of their procedures, though there are also many common elements. In winter [though some do it in summer], fasting and nightly vomiting are practiced for at least 3 days before the quest, particularly excluding salt, grease, meat and blood. During the day, the 'novice' is taken to an isolated and exposed place, and laid on his back. The appointed elder [the 'ant doctor'] feeds him live ants that have been collected on moist balls of eagle down, which are thoroughly swallowed in large quantity. Up to 90 or more such balls may be swallowed in a single session, each holding 5 or so ants. Bloodshot eyes and lassitude indicate a sufficient dose, upon which ingestion ceases. Shortly after, the ant doctor sneaks up on the novice and shakes him, to agitate the ants into biting, causing him to fall into a stupor for about 8-10hrs. After awakening, hot water is drunk to induce vomiting, the balls of down being regurgitated with the ants still alive [when ingested for curing, it may be taken as a bad sign if the ants are dead]. Occasionally, after awakening, more ants may be consumed, continuing the process for several days if required. Following the ritual, further dietary restrictions may be adhered to for some time, as well as behavioural restrictions including isolation and not speaking. The experience induces visions in a dream-like state, and aids in the gaining of 'supernatural powers' thought to be necessary for everyday survival.

The ants used have not yet been specifically identified, though Pogonomyrmex californicus ['California harvester ant'] seems to be the most likely candidate. There has been a report of the ritual consumption of yellow ants amongst the Tubatulabal, and if accurate, the ants in this case might be Myrmecocystus testaceus ['yellow honey ant']. Various red ants have also been used in smaller doses medicinally [internally and/or externally] to treat rheumatism, paralysis, body pain, stomach aches, heavy colds and some gynaecological disorders, in ways that reflect some facets of the ritual ingestions, though visions are usually not sought or received. All tribal groups who use ants ritually also use them medicinally, but not all who use them medicinally use them ritually. Californian 'ant ordeals', in which boys are made to lie over a disturbed ant nest until losing consciousness from the bites, seem to be unrelated to the ritual uses mentioned above, and were performed as "general preventative medicine which imparted strength, fortitude, and endurance" (Groark 1996). Interestingly, in 1967 [earlier than any published reports of ritual ant ingestion], the Californian band 'The Ant Trip Ceremony' released their album '24 Hours', complete with great psychedelic cover-art suggesting a possible knowledge of the ritual ant ingestions mentioned above.

In parts of the Peruvian Amazon, large ants known as 'isula' [possibly Paraponera clavata] are used in shamanic initiation (Luna & Amaringo 1991); unfortunately, I do not have access to further details, which are referred to Luna (1986) [Vegetalismo Shamanism Among the Mestizo Population of the Peruvian Amazon. Stockholm, Almquist & Wiksell Int.].

Interestingly, ants have been used as an aphrodisiac stimulant in wine, said to have been consumed by soldiers to give courage for battle. Large, sour-tasting ants were said to be the best to use in the preparations. One consisted of macerating 2 handfuls of ants in a gallon of wine for a month, before distilling and repeating the procedure 3 times with fresh batches of ants. Cinnamon [see **Cinnamomum**] was added to the combined distillates, and the oil floating on top removed. A second preparation used 1 handful of ants, 200 ant eggs, 100 wood lice and 150 bees [see above], macerated for a month in 2 pints of wine, which was then decanted and stored for use (Heydon 1662). An early issue of High Times magazine contained an article on smoking ants for psychotropic effects (friendly pers. comm.), though I lack further details. A more recent report stated that in Dubai, Bahrain, teenagers have been arrested for being intoxicated after "smoking ants or sniffing the fumes they emit when crushed" (Anon. 1997). In China, ants and ant extracts are known as 'ma yi' and are commonly taken daily [6-10g] as a tonic food and medicine, used to treat sexual disorders, rheumatoid arthritis, hepatitis, diabetes, pain, convulsions, asthma, cancer, anxiety and insomnia. They also stimulate the spleen, thymus and immune system, and may retard aging; toxicity appears to be a non-issue. The ants usually used are Polyrhachis spp. such as P. vicina and P. lamellidens [types of 'weaver ants'], and Formica fusca ['fuscous ant']; they are killed by steam before processing. Wild-harvesting appears to be driving these ants to extinction, making farming operations preferable as a source. These weaver ants may contain 42-67% protein, as well as amino acids, vitamins and minerals, with particularly high levels of zinc; F. fusca has also yielded formic acid, farnesene, isoxanthopterin, biopterin, 2-amino-6-OH-pteridine and aliphatic hydrocarbons (Chen & Alue 1994; Huang et al. 1999; Kou et al. 2005); F. rufa contains *norepinephrine* (Numata & Ibuka 1987). A bioassay of one 'red and black ant' extract was described as "very nice [...] clean, clear, energising but not overamping or jittery" (Trout pers. comm.).

Ant venoms are highly complex, and their chemistry is still relatively poorly known. As well as being useful in defense, constituents of ant venoms also sometimes serve as pheromones for communication purposes. Venoms of Pogonomyrmex spp. ['harvester ants'] are reported to be the most toxic insect venoms known, the most potent being from P. maricopa; ants from this genus are notorious for the intense, piercing pain resulting from their bites. They contain neurotoxic peptides, as well as haemolysins, and enzymes such as phospholipase A2, phospholipase B, hyaluronidase, lipase, acid phosphatase, and 4 esterases. Some species contain substances with kinin-like agonist properties, though P. badius did not contain any appreciable levels of kinin-like peptides [eg. bradykinin – see *Neurochemistry*] (Groark 1996; Schmidt & Blum 1978).

Piperidine alkaloids have been found in 'fire ants' [Solenopsis spp.], and some 'thief ants' [Solenopsis subgenus Diplorhoptrum] contain piperidines, pyrrolidines and indolizidines. Pyrrolidines and indolizidines have also been found in Monomorium spp. Some 'leaf-cutting ants' [Atta spp. and Acromyrmex spp.], as well as Tetramorium caespitum, Wasmannia auropunctata, Calomyrmex spp., Hypoponera opacior, Odontomachus spp. and Ponera pennsylvanica contain pyrazines. *Anabasine* has been found in the venoms of Aphaenogaster fulva and A. tennesseensis. Venom from Myrmecia spp. is rich in *histamine*. The indole skatole has been found in Acanthomyops claviger, Lasius aliensus, L. neoniger, Neivamyrmex nigrescens and Pheidole fallax (Numata & Ibuka 1987). Many ants have been found to contain potentially psychoactive cat-attracting lactones, previously known from **Nepeta** and **Actinidia** [also see above]. An Australian ant, Dolichoderus diceratoclinea scabridus, and an Argentinian ant Iridomyrmex humilis, contain iridomyrmecin; another Australian ant, I. nitidus contains isoiridomyrmecin as well as isodihydro-*nepetalactone*; a N. American ant, I. pruinosus analis contains iridomyrmecin; the 'common meat ant' I. purpureus contain dihydro-*nepetalactone* and iridomyrmecin; and the N. American 'odorous house ant' Tapinoma sessile contains isoiridomyrmecin (Numata & Ibuka 1987; Tucker & Tucker 1988). *Actinidine* has been found in T. erraticum and T. melanocephalum (Buckingham et al. ed. 1994).

In TCM, the cast-off skin of the 'cicada' Cryptotympana atrata is used as a sedative, anticonvulsant and hypothermic, properties which have been verified experimentally; sedative effects may be due to increased serotonergic activity and decreased catecholaminergic activity in the CNS (Hsieh et al. 1991). The cicadas Cicada sp. and Huechys sp. are also said to have aphrodisiac properties, as are some other insects not mentioned elsewhere, including Chrysomya sp. ['blow fly'] pupae, Cybister tripunctatus ['yellow fire beetle'], Dynastes hercules ['Hercules beetle'], Golofa aegon ['saw beetle'], Libellula spp. ['dragonflies'], Lytta vesicatoria ['Spanish fly' - see *Methods of Ingestion*], Meloë spp. ['oil beetles'; related to Lytta spp., and also contains cantharidin], Mylabris cichori and M. sidas ['ban mao', 'blister beetles'], Oryctes rhinoceros ['rhinoceros beetle'], Oxynopterus mucronatus ['fast beetle'], Phyllophaga spp. ['June bugs'; sacred to Freya, Germanic love goddess], Polyphaga plancyi ['tree bug'] and 'whirligig beetles' of the Gyrinidae (Rätsch 1990). 'Scarab beetles' [a.k.a. 'dung beetles'], Scarabaeus sacer, have been ritually consumed in Sudan by adherents of a supposed remnant Osiris cult (Emboden 1979b); it was not reported whether there was any pharmacological basis for this. In Garwhal, India, the 'plant-hopper' or 'lantern insect' Phromnia marginella has been used as an obscure narcotic (Reichel-Dolmatoff 1975).

In e. Namibia and Botswana, the Kung use pupae of the beetles Diamphidia nigro-ornata, D. vittatipennis and Polyclada flexuosa (Chrysomelidae) to prepare arrow poisons for hunting. The host plants for these pupae are Commiphora angolensis, C. africana (Burseraceae) and Sclerocarya caffra [see above], respectively. Commiphora spp. are used to produce the incense 'myrrh'. At least one Kung Bushman has been observed smoking the dried and pulverised pupae of one of these species with tobacco [see **Nicotiana**]; this person "fell into an inebriated and hallucinogenic state". These three species are sometimes parasitised by 'carabid beetles' of the genus Lebistina (Carabidae), which are reputedly more toxic than the pupae which they infest. For this reason, parasitised specimens are preferred for use in arrow poisons. D. nigro-ornata pupae have yielded diamphotoxin, a polypeptide which acts as a potent neuromuscular blocker and haemolytic, as well as showing some cardiotoxicity. In mice, 1.15μg/kg [i.v.] was lethal (De Smet 1998; Robertson 2003).

'Ladybirds' of the genus Coccinella have been claimed to be aphrodisiac (Rätsch 1990). At least one individual in the US has reportedly smoked crushed and dried shells of 'common ladybugs' [species or description not reported] for the "*morphine*-like" effects they produced (Trout pers. comm. [note – it was not Trout who actually did this!]). Though I would not encourage such a practice, and the person involved may have been an unreliable source of information, alkaloids have been found in the defensive secretions of some species of ladybugs/ladybirds. These secretions consist of droplets of blood containing deterrent chemicals. The secretions of Coccinella septempunctata ['common European ladybug'] have been found to contain coccinelline and precoccinelline. A homotropane alkaloid, adaline, has been found in Adalia spp. secretions, and the similar euphococcinine was found in secretions from Cryptolaemus montrouzieri ['Australian mealybug ladybird']. Other ladybug alkaloids include convergine, harmonine, hippocasine, hippodamine, myrrhine, n-octylamine and propyleine (Numata & Ibuka 1987).

In Arnhem Land, n. Australia 'bush cockroaches' [Cosmozosteria sp.] are used for analgesic purposes, producing a quick-acting "sensation of numbness" to relieve stings. The cockroaches are either crushed and rubbed on the skin, or they are heated over a fire and the juices dripped onto the skin (Low 1990). Many cockroaches contain uric acid, and pteridines such as xanthopterin, isoxanthopterin and 2-amino-6-OH-pteridine. *Dopamine* and *serotonin* have been found in the nerve cord of the American cockroach Periplaneta americana (Numata & Ibuka 1987).

Several different insects have been found to contain detectable levels of neurotransmitters and other substances of interest. A 'mealworm beetle' [Tenebrio moritor] contains *epinephrine*, *norepinephrine* and *dopamine*; housefly larvae [Musca domestica] also contain these compounds, as do 'earwigs' of the genus Forficula. The defensive secretions of the 'harvestman' [Sclerobunus robustus] contain mostly N,N-dimethyl-*phenethylamine*, as well as *nicotine* (Numata & Ibuka 1987). The 'mealy bug' Nipaecoccus aurilanatus contains *hypericin* (Buckingham et al. ed. 1994). Other insects, besides the ants mentioned above, have also been found to contain cat-attracting compounds which may be psychoactive. 'Rove beetles' of the genera Cafius, Creophilus, Gabrius, Hesperus and Philonthus produce *actinidine* in their defensive secretions; Creophilus maxilosus also produces dihydro-*nepetalactone*. Defensive secretions of the 'coconut stick insect' [Graeffea crouani] contain *nepetalactone* (Tucker & Tucker 1988). Various female aphids produce *nepetalactone*-derivatives as pheromones; mixtures of (4aS,7S,7aR)-*nepetalactone* and (1R,4aS,7S,7aR)-nepetalactol are found in the 'black bean aphid' [Aphis fabae], 'vetch aphid' [Megoura viciae], 'greenbug' [Schizaphis graminum], and Cryptomyzus galeopsidis, C. maudamanti and C. ribis; the 'damson-hop aphid' [Phorodon humuli] produces only (4aR,7S,7aS)-nepetalactol (Guldemond et al. 1993). Spines of the 'stinging caterpillar' Automeris sp. [possibly A. ilustris] have yielded 0.0235% *serotonin* (Welsh & Batty 1963).

MOTHS, BUTTERFLIES and THEIR LARVAE

The larva of the moth Myelobia smerintha (Pyralidae/Crambidae), known as 'bicho de tacuara' ['bamboo worm'], was consumed by the Malali of Brazil [Minas Gerais province] for several purposes. Usually, the head and intestinal-tube were removed, and the flesh either sucked out, or cooked over a fire into a greasy mixture, eaten as a delicacy. They may be dried and powdered to speed the healing of wounds. Most interestingly, they were eaten [dose – 1 grub] dried with the 'poisonous' head [but not the intestinal tube] removed as an ecstatic narcotic, causing a sleep-like state with vivid imagery lasting more than a day. The grubs are found in flowering bamboo [see above] stalks [Guadua sp., Merostachys neesii, M. rideliana, Nastes barbatus], feeding inside the internodes, and were gathered when full size, shortly before metamorphosing (Britton 1984; Saint-Hilaire 1824). Descriptions of it may be found in Dusenia 12(3):73-94(1980), 14(3):95-111(1984) and 14(4):161-173(1984). Presumably the larvae accumulate psychotropic compounds from the bamboo on which they feed. Butterfly larvae of the Lepidoptera have been known to do just this with phytochemicals from other host-plants – such as the grubs of Battus philenor [aristolochic acid], Danaus chrysippus, D. plexippus [cardenolides][see below], Pachlioptera aristolochiae [aristolochic acid] and Papilio antimachus [cardenolides]. Some secrete their own toxins, such as Arctia caja [β,β-dimethylalcrylvyl-*choline*], Callimorpha jacobaeae [*histamine*], Utethesia bella [β,β-dimethylalcrylvyl-*choline*] and Zygaena spp. [hydrocyanic acid] (Rothschild et al. 1970). *Histamine* has been found in moths of the genera Euproctis, Bataraea, Dirphia, Latoia, Megalopyge and Monema (Numata & Ibuka 1987).

Many people will be aware of the widespread belief that the worms ['gusano de mescal', actually larvae] found in many bottles of mezcal or mescal [a liquor distilled from Agave spp. - see *Methods of Ingestion*] have psychedelic properties. Some say you must drink the mezcal then eat the worm (pers. comms.); others say eating 2-3 worms is sufficient for a dose (Rätsch 1998). In Japan they are considered aphrodisiacs (Walker 2005). However, no psychoactive effects have been confirmed and it seems most likely that this modern mythological drug acts as a placebo for people who are already drunk and may have the false belief that mezcal is made from a *mescaline*-containing cactus (pers. obs.). The addition of the worms is not traditional, but has persisted largely because western consumers have come to expect it (Walker 2005). Actually, several different types of 'worm' are added to mezcal and then, only the cheaper varieties; top-shelf mezcal, and tequila - which is a specialised kind of mezcal made from a particular Agave spp. in a particular area of Mexico - contain no worm. The most commonly used are the moth larvae of Hypopta agavis (Cossidae), known as 'gusano rojo', 'chilocuil', 'chinicuil' or 'tecol', which feed on Agave spp.; they are also eaten by humans as food. Larvae of the 'Agave snout weevil' or 'picudo del Agave', Scyphophorus acupunctatus (Curculionidae), are occasionally added to mezcal; these larvae also live on Agave spp. and are eaten as a food, but they are a serious pest and damage the crops. There are other larvae that live on Agave spp. and are eaten by people, such as the larvae ['white maguey worms'] of the 'tequila giant skipper' butterfly Aegiale hesperiaris, but they are not known to end up in mezcal (http://en.wikipedia.org/wiki/Mezcal_worm and embedded links).

The silk pod of the 'silk worm moth' Bombyx mori is said to be aphrodisiac in India (Nadkarni 1976). In TCM, the silk worm moth itself is taken as a nerve stimulant and impotence treatment; the excrement of the larva is used as a sedative and analgesic (Keys 1976). B. mori larvae infected with the fungus Beauveria bassiana are used as 'jian can' in TCM, and act as a hypnotic, sedative, anticonvulsant and spasmolytic (Huang 1993). B. mori feeds on **Morus** spp., and accumulates some of the alkaloids from these trees; B. mori feeding on M. alba was shown to contain 0.188% 1-deoxynojirimycin, 0.0125% fagomine, 0.0021% 3-epi-fagomine, 0.0065% 1,4-dideoxy-1,4-imino-D-arabinitol and 0.0041% 1,4-dideoxy-1,4-imino-(2-O-β-D-glucopyranosyl)-D-arabinitol (Asano et al. 2001); 3-OH-L-kynurenine [see *Neurochemistry* for kynurenine] has also been isolated from B. mori (Tokuyama et al. 1967), as well as kynurine, xanthurenic acid, 4,8-dihydroxyquinoline, dimethylamine, putrescine, spermidine, and a range of pteridines (Numata & Ibuka 1987).

Several people in New Zealand have reported an unusual practise – the consumption of the left wing of a 'monarch butterfly' [Danaus plexippus], for an experience described as "like a mushroom/acid trip that lasts about 20min." (pers. comm.). The truth of these claims would seem to be dubious at best – the insistence on the use of only the left wing, and the claim that only one wing is consumed, are the most obvious points to raise suspicion. However, these reports should not be ignored out of hand – they may turn out to be true! Nevertheless, I would not encourage the maiming of innocent butterflies in order to find out.

D. plexippus usually feeds on Asclepias spp., and contains 3-alkyl-2-MeO-pyrazines as odour compounds. Danaus spp. males have also been found to contain the pyrrolizidine alkaloid danaidone, and the aldehydes danaidal and 3-OH-danaidal, in their wing pockets; danaidone acts as an aphrodisiac pheromone during courtship. For this purpose, the butterflies first dip their abdominal scent organs ['hair pencils'] into the wing pockets to obtain a coating of danaidone. The danaidone, and related compounds, are thought to be biosynthesised from pyrrolizidine precursors ingested from their plant diet, such as lycopsamine, from Heliotropium spp. (Numata & Ibuka 1987). Wings of some butterflies [eg. **Heliconius**, Ithomiinae] have been found to contain the pigment 3-OH-L-kynurenine (Tokuyama et al. 1967), which might have psychoactive effects [see *Neurochemistry*]. Buckingham et al. ed. (1994) erroneously reported these butterflies to contain kynurenine yellow [1,2,3,4-tetrahydro-4-oxo-2-quinolinecarboxylic acid], instead. Wings of butterflies commonly contain pteridine alkaloids. Larvae of the butterfly Vanessa urticae contain *dopamine* and *norepinephrine* (Numata & Ibuka 1987). The butterfly Papilio xuthus contains 5-MeO-*N*-*methyltryptamine* in its oviposition-stimulating complex (Buckingham et al. ed. 1994). See also **Acraea** and **Heliconius**.

MARINE LIFE

Many marine life-forms are being found to bear some interesting alkaloids and other chemicals. Here we will look at a few which contain β-carbolines, *tryptamine*s, or other compounds of potential psychoactivity.

Astroides calycularis (Anthozoaceae) from the Bay of Naples has yielded *tryptophan*-derivatives such as aplysinopsin, 6-bromoaplysinopsin, and their N-propionyl derivatives (Fattorusso et al. 1985).

A Bryopsis sp. (Bryopsidaceae) 'hair algae', associated with marine reefs and used in aquariums, has yielded 5-bromo-*DMT* and 5,6-dibromo-*DMT* (Kochanowska et al. 2008).

Conus spp. (Molluscidae), marine snails known as cone shells and associated with reefs, paralyse their prey with highly toxic venom. These venoms have been found to produce interesting polypeptides with therapeutic potential. One such compound undergoing human clinical trials is omega-conotoxin MVIIA [Ziconotide, Prialt and SNX-111 are some commercial names] from C. magus, used to treat chronic pain. It acts as a voltage-sensitive N-type calcium channel blocker. Though more effective than *morphine* as an analgesic, it must be administered intrathecally [into the meninges of the spinal cord; usually 1 microgram per hour], and higher doses give rise to side effects such as nausea, vomiting, dizziness, confusion, delirium, amnesia, hallucinations, 'psychosis', impaired concentration, slowed thinking, tunnel vision, sedation, nystagmus, constipation, urine retention, abnormal gait and hypotension. On the positive side, it does not produce respiratory depression, tolerance or withdrawal symptoms, and has a wide margin of safety (Charapata & Ellis 2002; Levin et al. 2002; Taqi et al. 2002; Wang & Bowersox 2000; Webster, L. et al. 2001). Recently, conotoxin Vc1.1 [named ACV1 for commercial development] was isolated from C. victoriae (Livett pers. comm. 2003) and found to act as an analgesic more potent and of longer duration than either *morphine* or other known conotoxins, as well as accelerating tissue repair in damaged nerves. Further advantages are that it showed no adverse effects in rats over 12 weeks, and can be adminsitered i.m. It acts as an antagonist of nicotinic *acetylcholine* receptors (Brown 2002; Sandall et al. 2003; Satkunanathan et al. 2003). The varying affinities of some cono-

toxins for nicotinic receptor subtypes should aid in learning more about such subtypes, which are still little-known (Nai et al. 2003). C. textile has been found to contain novel conotoxins, epsilon-TxIX and Gla(1)-TxVI (Kalume et al. 2000), as well as peptides named contryphans (Jiminez et al. 2001). C. lynceus has been found to contain the peptide conantokin-L. Conantokins are NMDA receptor antagonists and act as powerful anticonvulsants (Jiminez et al. 2002).

Costaticella hastata (Bryozoaceae) from Tasmanian waters has yielded 0.11% alkaloids, consisting of 0.016% *harman*, 0.006% 1-ethyl-β-carboline and 0.006% 1-(1'-hydroxyethyl)-β-carboline; another collection yielded 0.051% *harman*, 0.0048% 1-ethyl-β-carboline, 0.002% 1-(1'-hydroxyethyl)-β-carboline and 0.018% pavettine [1-vinyl-β-carboline] (Blackman et al. 1987).

Cribricellina cribraria (Bryozoaceae) from New Zealand waters has yielded 0.003% *harman*, 1-vinyl-β-carboline, 0.01% 8-OH-1-vinyl-β-carboline, 0.002% 1-ethyl-4-methylsulfone-β-carboline, 0.058% homarine and 1-ethyl-β-carboline (Prinsep et al. 1991).

Dendrodoa grossularia (Styelidae), a 'tunicate', has yielded 5 indole alkaloids – dendrodoine, 3-indolylimidazol-4-one, grossularine-1, grossularine-2, and an unnamed alkaloid (Loukaci et al. 1998).

A Didemnum sp. (Didemnidae), another tunicate, has yielded *norharman*; D. candidum yielded 0.015% 6-bromo-*tryptamine*, as well as 0.023% 2,2-bis(6'-bromo-3'-indolyl)ethylamine and 0.01% 2,5-bis(6'-bromo-3'-indolyl)piperazine (Fahy et al. 1991).

Eudistoma fragum (Ascidiaceae), a 'sea squirt' from near New Caledonia, has yielded 0.02% 5-bromo-*DMT* and 0.01% woodinine [6-bromo-1-(N-methylpyrrolid-2-yl)-1,2,3,4-tetrahydro-β-carboline] (Debitus & Laurent 1988).

Eudistoma glaucus has yielded 1,2,3,4-tetrahydro-β-carboline and some of the compounds found in Eudistoma olivaceum, which has yielded a wide array of β-carbolines called eudistomins, some of which have been shown to possess antiviral properties (Blunt et al. 1987; Kobayashi et al. 1984; Rinehart et al. 1984).

Flustra foliacea (Bryozoaceae), 'hornwrack', has yielded [w/w] 0.005% flustrabromine [6-bromo-2-(1,1-dimethylallyl)-N-formyl-*N-methyltryptamine*], 0.002% 6-bromo-N-methyl-N-formyltryptamine, 0.005% flustramine A [a physostigmine-derived bromo alkaloid], flustramine C, flustraminols A & B, and 7-bromo-4-(2-ethoxyethyl)quinoline (Wulff et al. 1981, 1982a, 1982b). It is found worldwide in waters below 25m, as greenish-brown branching colonies adhering to broken shells and coral moss (Grzimek 1974).

A Lissoclinum sp. (Didemnidae) has yielded 6-bromo-*tryptamine*, and L. fragile has yielded 1-(indol-3-yl)-3,4-dihydro-β-carboline (Shulgin & Shulgin 1997).

Noctiluca miliaris (Dinoflagellidae/Noctilucaceae), a 'dinoflagellate', has yielded *harman* and *norharman* (Shulgin & Shulgin 1997).

Pachymatisma johnstoni (Geodiidae) from near Britain has yielded 6-bromohypaphorine [6-bromo-N,N,N-trimethyl-*tryptophan*], *tryptophan*, thymine, uracil, cholest-4-en-3-one and 24-methylenecholest-4-en-3-one (Raverty et al. 1977). See **Erythrina** for discussion on the potential uses of hypaphorine.

Paramuricea chamaeleon (Paramuriceidae) ['violet horny coral'], a 'sea fan' from the Bay of Naples 20m and below, yielded *tryptamine*, *serotonin*, 0.0025% *DMT*, 0.005% *bufotenine* and 0.015% *N-methyltryptamine* (Cimino & De Stefano 1978), as well as 0.045% *caffeine* (Imre et al. 1987). It is large [1m] and multicoloured, from carmine-red, to violet to bright yellow (Grzimek 1974).

Pseudoactinia flagellifera and P. varia (Annelidae) ['sea worms' or 'anenomes'] have yielded an unidentified 5-hydroxy indole (Christopherson 1985).

A Raspailia sp. (Raspailiidae) [a New Zealand 'sea sponge'] has yielded clerodane diterpenes [see **Salvia**], raspailol and raspailenone (West et al. 1998).

Securiflustra securifrons (Bryozoaceae) has yielded unidentified bromoindoles, as has Chartella papyracea (Christopherson 1985).

Some Thorecta spp. (Demospongiae) and Verongia spp. (Verongiidae) [sea sponges] have yielded the indole N-methylaplysinopsin, which is an antidepressant and short-term competitive MAOI (Christopherson 1983; Fattorusso et al. 1985). V. cauliformis and V. fistularis have yielded 2,6-dibromo-4-acetamido-4-OH-cyclohexadienone, which has antibiotic properties (Baslow 1977).

Verongula gigantea (Verongiidae) ['giant marine horny sponge'], found near coasts in the Caribbean, has yielded 5,6-dibromo-*DMT* and aureol from one sample; others did not contain them at all, and they are believed to be of dietary origin. This species is usually known to produce bromo-tyrosine derivatives and other brominated compounds, such as the aeroplysinins and verongamine (Ciminiello et al. 2000). V. rigida from Key Largo, Florida, yielded 0.35% 5,6-dibromo-*DMT*, 0.00142% 5-bromo-*DMT*, 0.0154% aplysinopsin, 0.00094% 6-bromo-aplysinopsin [binds to 5-HT2 receptor subtypes], 0.00047% 5,6-dibromo-abrine, 0.00236% ilimaquinone, 0.00094% aureol, 0.00014% arborescidine C and 0.000047% makaluvamine (Kochanowska et al. 2008).

Villagorgia rubra [a 'sea fan' from New Caledonia] has yielded *tryptamine*, *N-methyltryptamine*, 1,2,3,4-tetrahydro-β-carboline [noreleagnine], *caffeine*, villagorgin A [anticholinergic] and villagorgin B; the villagorgins have structural similarity to *yohimbine* and corynantheine, as well as to eudistomin A (Espada et al. 1993).

It has been suggested that the Maya used molluscs of the genus Spondylus as a 'hallucinogen'. The Maya are known to have revered these molluscs to some degree; they are associated with Chaak, the rain god, and are "often found in graves and sacrificial depositories" by archaeologists (Grube et al. ed. 2001). Molluscs in general are associated with Aphrodite and the female reproductive organs, due to their physical form; as such, they are also widely credited with aphrodisiac properties (Rätsch 1990). Pearls from 'pearl mussels' such as Mytilus margaritiferus [Pinctada margaritifera] are reduced to ash in India and used as a strong stimulant, tonic and aphrodisiac. In TCM, they are used in doses of 0.4-1.1g as a sedative to treat insomnia, headache and convulsions. And, of course, oysters [Ostrea spp.] are eaten raw or cooked as an aphrodisiac. The shells of the 'sea ear' or 'abalone' [Haliotis gigantea] and the 'cowrie' [Cypraea macula] are used as sedatives (Keys 1976; Nadkarni 1976). C. pantherina, C. moneta and Haliotis spp. flesh has also been eaten as an aphrodisiac. Other molluscs credited with this property include Achatina sp. ['African snail'], Donax sp. [a clam], Crassostrega gigas [another kind of oyster], Helix pomatia [edible snail], Murex brandaris, M. truncata, Octopus sp. [octopus], Sepia sp. ['cuttlefish'], Strombus sp., Turbinella pyrum, and 'scallops' of the Pectinidae (Rätsch 1990). The opercula of sea snails or so-called 'conch shells' from the genera Ampularia, Chicereus, Fasciolaria, Murex and Turbinella ['true' conches being Strombus spp.] are used by Nepalese Brahmins in incense, known to the Kirati as 'kulkelengma' or 'narawi' [and known as 'onchya' and 'onyx' in the past]. They are regarded as a protectant. The incense is said to smell like burning hair on its own, "but adds an interesting note to a blend" (Müller-Ebeling et al. 2002).

The ovaries of various species of 'sea urchin' [Echinidae] have been eaten as aphrodisiacs of debatable efficacy. In Japan, as 'uni', they are used in sushi. These ovaries are often referred to as the 'roe' or 'eggs', which is not accurate (Rätsch 1990; Sushi FAQ 2008). Ovaries of Paracentrotus lividus have been found to contain small amounts of *anandamide* and related palmitoyl- and stearoyl-ethanolamides (Bisogno et al. 1997); in rabbits, the ovaries have caused "loss of reflexes, exophthalmos, micturition, lacrymation, dilatation, tonic and clonic convulsions, respiratory distress, muscular paralysis and death". Spines of sea urchins also contain little-known toxins. For example, in humans, a Toxopneustes pileolus sting can cause "severe pain, respiratory distress, giddiness, paralysis of the lips, tongue and eyelids, relaxation of the muscles in the limbs, difficulty in speech and loss of control of facial muscles", with the facial paralysis being the most long-lasting symptom [6 hrs] (Baslow 1977). Perhaps they contain tetrodotoxin, amongst other things?

Tetrodotoxin [TTX] is a potent neurotoxin, best known from 'puffer fish' such as Takifugu spp. ['fugu']. Fugu fish are a popular luxury cuisine, prepared by specially trained chefs who remove the toxic portions [ie. most of the fish] leaving just enough TTX to give the diner "tingling lips and a mild sense of euphoria", though mistakes can prove fatal (Booth 1988; Davis 1988b; Kodama et al. 1986). TTX can cause feelings of weakness, dizziness and anaesthesia; the tingling may spread from the lips to the extremities, and in acute intoxication there is often nausea, vomiting, sweating, salivation, respiratory difficulties and cyanosis; muscular paralysis and death can occur 6-24hrs after ingestion, with a sufficient dose (Baslow 1977). The related Tetraeodon [Tetrodon] fahaka, a freshwater Egyptian fish known as 'fahaka' or 'tambera', appears to have been venerated in the temples on Elephantine, an island in the Nile, until at least 2500-1500BC. The absence of bones of this species amongst fish bones found in the temples is thought to perhaps be due to careful disposal of the remains [if it was a sacred food], or the existence of a tabu on its consumption. This fish is known to be tetrodotoxic (Brewer & Friedman 1989). See also *Methods of Ingestion* for use of similar tetrodotoxic fish in zombi powders.

TTX has also been found in small amounts outside of this group of fish, such as in the 'marine flatworm' Planocera multitentaculata (Miyazawa et al. 1986), the 'starfish' Astropecten latespinosus and A. polyacanthus (Maruyama et al. 1984), the 'blue-ringed octopus' Hapalochlaena maculosa (Sheumack et al. 1978) and some amphibians [see below].

The poor 'sea horse' Hippocampus coronatus is used in TCM [dose 4-10g] as a tonic stimulant (Keys 1976), and members of the genus are reputedly aphrodisiac. Other sea creatures not yet mentioned which are said to have aphrodisiac properties include the red coral Corallinum rubrum, Solenognathus hardwickii ['sea dragon'; taken dried , in wine], Alburnus alburnus ['ukelei' fish], Barbus spp. ['barbel' fish], Diodon hystrix ['spotted porcupine fish' - see *Methods of Ingestion*; all parts used except liver and gall bladder], Siniperca chuatsi ['kuei', 'mandarin fish', 'Chinese perch', 'Chinese bass'], eels, carp gall bladder, and various crustaceans – Brachyura spp. [crab], Homarus grammarus [lobster], Natantia spp. [prawn], Palinurus vulgaris [crayfish] and Penaeus setiferus [shrimp] (Rätsch 1990).

AMPHIBIANS

Skins of two frogs, Litoria angiana ['kuuroorong'] and Phyrnomantis lateralis ['kuutuuk'], are consumed along with other psychoactive substances in the 11th and 12th stages, respectively, of Bimin Kuskumin initiation in Papua New Guinea [PNG] (Poole 1987). Phyrnomantis spp. are known as 'rubber frogs', and some species are known to exude toxic secretions, contact with which may cause rash, inflammation, pain, local paraesthesia, respiratory difficulty, headache, dizziness, tachycardia, diaphoresis and nausea (Pantanowitz et al. 1998). *Histamine* has been found in secretions of some Phyrnomantis spp. (Daly et al. 1987).

Litoria dentata [Hyla dentata] skin has yielded 0.075% *bufotenine*; L. pearsoniana [H. pearsoniana] skin yielded 0.075-0.7% *bufotenine*, with 0-0.035% bufotenidine [see **Bufo**, **Arundo**]; L. peroni [H. peroni] skin yielded 0.001-0.0015% *bufotenine*. *Bufotenine* is also found in the skins of L. adelaidensis [0-0.01%, as well as 0.03-0.12% bufotenidine, 0.015-0.06% *serotonin*, 0.0075-0.014% N-methyl-*serotonin*, and other indoles], L. chloris [0-0.002%] L. ewingi [0.087-0.23%, as well as 0.027-0.028% bufotenidine], L. gracilenta [H. gracilenta] [0.0025%], L. lesueuri [H. lesueuri] [0.0005%], L. rubella [H. rubella] [0.001-0.006%] and L. thesaurensis [0.0035%, as well as 0.035% bufotenidine] (Erspamer et al. 1966, 1976; Roseghini et al. 1976). Bufotenidine has also been found in the skins of L. angiana [0.0065%], L. booroolongensis [0.185%, as well as 0.05% *serotonin*], L. citropa [0.13%, as well as 0.16% *serotonin*], L. cyclorhynchus [0.08%, as well as 0.015% *serotonin*], L. glandulosa [0.6%, as well as 0.025% *serotonin*], L. latopalmata [0.003-0.019%], L. micromembrana [0.006%] and L. raniformis [0.16%, as well as 0.04% *serotonin*]. L. moorei skin has yielded 0.37-0.55% bufotenidine, 0-0.0008% *bufotenine*, 0.06-0.17% *serotonin*, 0.004-0.02% N-methyl-*serotonin* and 0.003-0.005% N,N,N-trimethyltryptamine (Roseghini et al. 1976), of unknown pharmacology. Synthetic 7,N,N-trimethyltryptamine has been shown to inhibit synaptosomal uptake of *serotonin* [and to a lesser extent, *norepinephrine* and *dopamine*] in rat brain (Glennon et al. 1978).

The common Australian green tree frog Litoria caerulea contains powerful peptides in its skin secretions. A single 'milking' by electrical stimulation of the parotoid glands produces a mixture of c.50mg peptides [20% caerulein, 10% of a mix of 6 different caeridins and 70% of a mix of 17 different caerins (mostly caerin 1.1)]. *Histamine* was also found in the skin [0.014-0.032%], as well as *serotonin* [0.018-0.05%]. L. gilleni has yielded caerulein, 3 caeridins and 12 caerins, as well as 0.006% *serotonin* from the skin. L. splendida has yielded c.70mg peptides per milking from its rostral and parotoid glands [c.23% caerulein, 36% caerin 1.1, 17% caerin 3.1, 7% caerin 2.1 and 3% caeridin 1]. Caerulein has analgesic effects, and acts potently on gastrointestinal smooth muscle, as well as affecting blood pressure (Erspamer et al. 1966, 1993; Roseghini et al. 1976; Stone et al. 1992, 1993; Waugh et al. 1993); it has been injected into schizophrenics in Japan, to alleviate psychotic symptoms for about 1 month (Morgan 1995; Tyler 1995).

Leptodactylus pentadactylus pentadactylus has yielded *histamine*, *tyramine*, 0.004% [of dry skin] candicine [4-OH-N,N,N-trimethylphenethylamine], large amounts of *serotonin*, leptodactyline [a phenolic quaternary alkaloid] (Erspamer et al. 1963) and 0.003-0.004% caerulein-like peptides. L. rugosus skin was found to be very rich in caerulein-like peptides [0.5%]. L. pentadactylus labyrinthicus has yielded 0.035-0.052% caerulein-like peptides (Erspamer et al. 1986), spinaceamine and 6-methylspinaceamine [see salamanders below], as well as *histamine*, N-methylhistamine, N-acetylhistamine and N,N-dimethylhistamine. L. laticeps also contains spinaceamine, as well as *histamine*, leptodactyline, *serotonin* and 0.07-0.1% caerulein-like peptides. L. pentadactylus dengleri has yielded 0.01-0.015% caerulein-like peptides, *histamine*, *serotonin*, bufotenidine, leptodactyline and possibly traces of candicine. *Bufotenine* and dehydrobufotenine have also been found in the genus. Other indole-containing genera of Hylidae frogs include Acris [dehydrobufotenine] and Nyctimystes [*bufotenine*, bufotenidine, N,N,N-trimethyltryptamine, N-methylhistamine, spinaceamines and indole] (Cei et al. 1968; Daly & Witkop 1971; Daly et al. 1987; Erspamer et al. 1964, 1986; Roseghini et al. 1986). Nyctimystes tympanocryptis skin yielded 0.51-0.95% bufotenidine; N. vestigea skin yielded 0.0065-0.055% bufotenidine; N. disrupta skin yielded 0.43% bufotenidine, 0.12% *serotonin*, 0.04% N-methyl-*serotonin*, 0.006% 5-OH-indoleacetic acid, 0.002% 5-OH-tryptophol, and 0.015% of an unidentified indole (Roseghini et al. 1976)

Rana temporaria also contains *bufotenine* (Cei et al. 1968; Daly & Witkop 1971), and numerous other Rana spp. have been found to contain peptides, such as ranatensin, bradykinins and bombesins (Erspamer et al. 1986). Leg flesh of Rana spp. is reputedly aphrodisiac (Rätsch 1990). Cyclorana alboguttatus skin has yielded 0.003-0.01% bufotenidine, 0.0005-0.0025% *serotonin*, 0.005-0.01% N-methyl-*serotonin* and 0.01-0.015% unidentified indoles; C. platycephalus skin has also yielded bufotenidine [0-0.004%], as well as 0.0007-0.001% *serotonin*, 0-0.008% N-methyl-*serotonin* and 0.01-0.015% unidentified indoles. Scaphiopus hammondii hammondii skin yielded 0.007% bufotenidine and 0.06% *serotonin* (Roseghini et al. 1986). Osteocephalus langsdorffii, O. oophagus and O. taurinus, Brazilian spiny-backed tree frogs, have been found to contain *bufotenine* (Costa et al. 2005); O. taurinus skin also contained 0.00015% leptodactyline and 0.00025% *serotonin* (Roseghini et al. 1986). Melanophryniscus moreirae toads from Brazil yielded large amounts of *bufotenine* [0.26-0.37% in skin], as well as *serotonin* [0.0025-0.003%] and N-methyl-*serotonin* [0.0022-0.0037%]; pumiliotoxin [see **Phyllomedusa**] has also been found. M. stelzneri skin also yielded *bufotenine* [0.0005%] (Cei et al. 1968; Daly et al. 1987). Melanophryniscus spp. have also been found to contain humopumiliotoxins, indolizidines, quinolizidines, pyrrolizidines and decahydroquinolines (Garraffo et al. 1993). A novel β-carboline, 1-(3-guanidinopropyl)-THβC, is found in the skin of the African frogs Hylambates maculateo and Kissina senegalensis (Shulgin & Shulgin 1997).

Tetrodotoxin [TTX; see above] has been found in the toads Atelopus chiriquiensis [also contains chiriquitoxin], A. ignescens [traces], A. oxyrhynchus [also contains 4-epi-TTX and 4,9-anhydro-TTX], A. spumarius [also contains 4-epi-TTX and 4,9-anhydro-TTX], A. spurrelli [minor component], A. varius [also contains 4-epi-TTX and 4,9-anhydro-TTX] and A. zeteki [traces; also contains zetekitoxin] (Daly et al. 1994; Kim et al. 1975; Yotsu-Yamashita et al. 1992), and a TTX-like compound, ephippiotoxin, was found in the frog Brachycephalus ephippium (Sebben et al. 1986). TTX has also been found in skin of the frog Colostethus inguinalis (Daly et al. 1994), as well as in some newts [Cynops sp., Notophthalmus sp., Taricha sp. and Triturus sp.] (Wakely et al. 1966).

Some salamanders have been rumoured to possess venoms with psychotropic activity. It has been claimed that a Dr. Edmund Brodie [famous herpetologist], who is very reluctant to discuss the incident anymore, was apparently fond of the practice of quickly licking the backs of amphibious specimens, to determine [by bitterness] whether or not they deserved chemical investigation. He tried this on a 'lungless salamander' from the cloud forests of Guatemala, Bolitoglossa resplendens. He noticed an immediate bitter burning taste and light-headedness, followed by bright 'psychedelic' lights and patterns, and apparently some degree of dissociation or amnesia. An eastern US species of Plethodon is also rumoured to be similarly active (pers. comms.). B. subpalmata skin has been found to contain 0.003-0.0035% *serotonin* (Roseghini et al. 1986). In addition, Salamadra sp. skin is reputedly aphrodisiac (Rätsch 1990).

Salamanders have long been associated with superstitions, and particularly with fire – sometimes they may nest in hollow logs, that would be unknowingly thrown on a fire, and the salamander would come running out, appearing to have been 'living' in the fire, which salamanders have been believed to do. The heat of the fire would no doubt induce the salamander to secrete venom as a reflexive protective measure (pers. comms.).

It is, of course, of interest to note that a 'salamander brandy' is made and consumed in mountain areas near Ljubljana, Slovenia, and reputedly has been since the Middle Ages, although it is an uncommon and fairly secretive pursuit. This beverage is made by one of several methods, using live salamanders [Salamandra salamandra]. They may either be placed in a barrel with fruit to ferment, dying before the resulting liquid is distilled; they may be placed in a sieve and soaked in brandy; or they may be suspended from a rope with warm, freshly distilled brandy being dripped over them. The last method is said to be best, and with the last two methods some expertise is required to delay the death of the salamander so that the maximum amount of venom is excreted [another method uncovered by Kozorog (2003) is passing the distillate vapour over the body of a dried salamander, before being condensed]. To make 30 litres of brandy, 5-6 mature salamanders may be used; a small amount of wormwood [see **Artemisia**] is also often added at the end to colour the drink and improve palatability; the brandy is aged with the wormwood for a couple of weeks before being ready. Salamander brandy needs to be shaken before drinking, to evenly distribute the cloudy venom residue; 50-200ml may be a dose. The effect of the drink is said to be similar to that of *muscimol*, *ibogaine* and *strychnine*, and to have a strong aphrodisiac element. The only side effects reported are occasional blackouts and amnesia of the experience. Regardless, larger doses may be more dangerous, as eating a single salamander can kill a dog. Many psychedelic enthusiasts believe making or consuming salamander brandy to be highly unethical, and decline to use it due to the belief that the drink contains negative energies derived from the torture involved in its production (Rätsch 1998; Valenčič 1996, pers. comms.).

However, later field work has cast doubt on the scenario described above. It appears that salamander brandy is indeed sometimes made, although as a means to produce intoxicating brandy in times of year when the required fruits are not in season. Such a practice is seen as deceptive and reprehensible by most locals, as these beverages are sold under the premise of being genuine quality brandy, and also are reputed to have the side effect of lower-limb paralysis. Also, 'salamander brandy' is often used as a general term for all suspect and adulterated brandies. This is reported to be the reason why its manufacture and dispersal are so secretive - social stigma rather than the hiding of esoteric knowledge. It seems that the only people who prepare and themselves consume brandy fortified with salamander venom, hoping for psychedelic effects, are city folk made curious

by the initial media reports (Kozorog 2003).

All salamanders have venom glands on their skin, and some of their venoms have toxic constituents [alkaloids and hemolytic proteins] that may cause excitation, convulsions and mydriasis, followed by increased blood pressure, depression and paralysis. Death sometimes occurs from respiratory paralysis. Antimicrobial, irritant, local anaesthetic and stomach-cramping actions have also been noted. Most of the alkaloids found in such venoms are of the oxazolidine [such as samandarine and samandarone, the major compounds from S. salamandra] and carbinolamine type [such as cycloneosamandaridine]; some contain *histamine*-derivatives called spinaceamines. *Tryptamine* is also found in the family Salamandridae [in S. maculosa and Triturus cristatus], as is tetrodotoxin [in some Ambystoma spp.]. *Serotonin* has been found in S. maculosa (Cei et al. 1968; Daly & Witkop 1971; Daly et al. 1994; Habermehl 1971; Mebs & Pogoda 2005; Shulgin & Shulgin 1997; Witkop & Gossinger 1983) and Bolitoglossa subpalmata [0.003-0.0035% in skin] (Roseghini et al. 1986).

REPTILES

Various species of turtle have been known to cause poisonings in humans who have eaten them; this is known as 'chelonitoxication'. Species implicated include Chelonia mydas ['green sea turtle', 'rock turtle', 'sand turtle'], Eretmochelys imbricata [Chelonia imbricata; 'hawksbill turtle', 'scute turtle', 'spectacled turtle'], Dermochelys coriacea ['leatherback turtle', 'seven-banded turtle'] and Terrapene carolina ['eastern box turtle']. The toxicity of these turtles is believed to derive from their diets, rather than from endogenously-produced toxins. In the case of the first three species mentioned, algae is believed to be responsible [see **Acanthurus et al.**], and E. imbricata also eats sponges [see above, and **Smenospongia**] which may also be involved in chelonitoxication; **Amanita** mushrooms have been hypothesised as the dietary toxin in the case of T. carolina. Such dietary toxins are apparently non-toxic to turtles, but may accumulate in flesh and thus are passed on to predators (Buden 2000; Halstead 1988; Kennedy 1982). Despite occasional toxicity, C. mydas is otherwise often eaten as food. This may also apply to other species involved – with toxicity only seen at some times of year or in certain locales, the flesh being safe and edible in other times and/or locales (Halstead 1988).

Kennedy (1982) claimed [without describing symptoms] that "the symptom picture sounds like indolic poisoning", hinting at some desirable psychotropic effect, yet the symptoms of chelonitoxication usually described seem rather undesirable and unrelated to symptoms of indole alkaloids in general. Symptoms may emerge from several hours to several days after consumption, initially consisting of severe pain in the upper gastric tract, nausea, vomiting, diarrhoea, vertigo, pallor, sweating, cold extremities and a burning sensation of mouth and throat. Sometimes there is tightness in the chest, and often difficulty in swallowing, excessive salivation, lethargy, diminished reflexes and headache. The tongue may also develop a white coating, followed by halitosis, and a covering of small red pustules which may remain for several months and sometimes turn into ulcers. Pronounced somnolence is often a sign that the victim is about to lapse into a coma, which is usually followed by death related to kidney and liver failure. In most cases [c.72% of those reported] however, victims survive (Halstead 1988). In cases of E. imbricata poisoning weakness, numbness and an inability to speak have also been reported. On Sapwuahfik Atoll, Micronesia, a form of E. imbricata implicated in poisonings is known as 'sirkitol', and is differentiated by its dark shell; the usual variety has a brightly-coloured and variegated shell, and is known as 'sapwake' (Buden 2000). Interestingly, on the n.w. coast of w. New Guinea, toxic turtles are reputedly differentiated by their long necks, black tongues and black marks under the chin, yet locals will still feed a sample of turtle meat to dogs or cats to test for toxicity. This might indicate that such visual clues have little bearing on toxicity (Halstead 1988). In TCM, shell of E. imbricata is used [3-8g] to treat febrile delirium, heat convulsions and blood poisoning (Keys 1976). Eggs, flesh and shell of Testudines spp. turtles are said to have aphrodisiac properties (Rätsch 1990).

Numerous other reptiles are reputed aphrodisiacs, such as the snakes Agkistrodon acutus ['sharp nosed pit viper', 'hundred pace pit viper', 'bai hua she' in TCM; taken in wine; has analgesic, sedative and vasodilatory effects], Boa sp. [boa constrictor], Bungarus multicinctus ['Chinese krait', 'Formosan banded krait'; in wine], Crotalus spp. [rattlesnakes and pit vipers] and Python sp. [a python], crocodile [Crocodylus spp.] eggs and tail flesh, iguana [Iguana iguana] flesh, 'monitor lizard' [Varanus salvator] scale exudate in wine, 'horned toad' [Phrynocephalus frontalis] and the 'skink' Lacerta scincus (Huang 1993; Rätsch 1990). In India, the 'sand lizard' Lacerta agilis [Agama agilis] is consumed in the form of ash [dose 0.3-0.5g] as a nerve tonic, stimulant and aphrodisiac; the flesh of the related L. vivipara is taken as a tonic stimulant, and its oil as an aphrodisiac. Oil from the 'Indian skink' Mabuia carinata is used as a restorative stimulant and aphrodisiac. In TCM, the tail of the 'red spotted lizard' Phrynosoma cornuta is used as a tonic stimulant, to treat asthma, neuraesthenia and pulmonary tuberculosis. The dose is one tail from a female and one from a male; they are considered mildly poisonous (Keys 1976; Nadkarni 1976). In Peru, a type of lizard known as 'cañanes' is consumed for its aphrodisiac properties, which are believed to derive from the immature fruits of **Prosopis** juliflora which it eats (Kennedy 1982). In Nepal, Kirati shamans say that geckoes of the genus Hemidactylus (Eublepharidae) have psychoactive properties, but they do not use them; many in Nepal believe that geckoes [and their bite] are poisonous, although nothing is known scientifically of toxicity from these reptiles. Some saddhus use the dried, pulverised tails for shamanic travel, either smoking them with **Cannabis** or drinking them in 'rakshi' [a local kind of schnapps] (Müller-Ebeling et al. 2002). Gekko gecko is taken dried, in wine, as an aphrodisiac (Rätsch 1990). Geckoes are used as a potent stimulant and stamina tonic by martial artists and athletes, and preparations are commercially available (Trout pers. comm.). However, I am forced to wonder how such an industry can be ethically or logistically viable.

See also *Methods of Ingestion* for uses of lizards in zombi potions.

OTHER FAUNA

Surprisingly, giraffes [Giraffa camelopardalis] have been reported to be psychoactive! The Humr Baggara of s.w. Kordofan in Sudan prepare a drink called 'umm nyolokh' from the liver and bone marrow of a giraffe, which is the main reason for hunting it. They say it makes them 'drunk', and hallucinations apparently occur both in a waking state and in sleep after drinking it. "It is said that a person, once he has drunk umm nyolokh, will return to giraffe again and again" (Rudgley 1998). Perhaps accumulation of alkaloids from the giraffe's **Acacia** diet plays a role (pers. obs.).

The Aztecs knew of a bird they called 'oconenetl', eating the flesh of which caused one to see visions. This bird is unidentified, and little is known of bird toxicology. Skin and feathers of S. American Pitohui spp. [P. dichrous, P. kirhocephalus and P. ferrugineus – decreasing in potency correspondingly] contain the steroidal alkaloid homobatrachotoxin [also found in some poison arrow frogs – see **Phyllomedusa**], which causes partial paralysis of hind limbs, locomotor difficulties and prostration (Dumbacher et al. 1992; Ott 1993). Batrachotoxins were also recently found in the feathers of some birds from New Guinea – Pitohui cristatus, P. dichrous, P. kirhocephalus, P. nigrescens, and Ifrita kowaldi. The highest levels were usually found in belly, breast, and leg contour feathers. They were not found in skin, and levels in feathers varied widely between different bird populations (Dumbacher et al. 2000). Thus, it is not unreasonable that birds could contain pharmacologically active compounds.

In Indian medicine, the flesh of the owl Athene brama indica ['ulooka'] is considered stimulant and useful in treating insanity; flesh of the 'house sparrow' Passer domesticus ['chataka'] is eaten as an aphrodisiac and cardiac stimulant; and flesh of the 'common Indian partridge' Perdix sylvatica ['krakara'] is eaten to improve memory and as a cardiac stimulant (Nadkarni 1976). Numerous birds reputedly have aphrodisiac properties, such as the chicken Gallus gallus [eggs, stomach, rooster genitals], the hummingbird Colibri sp. [unclear whether the dried bird is only used as a love charm, or consumed as well], the parrot Amazona farinosa, the 'petrels' Hydrobates spp. [bird's nest soup], the 'wryneck' Jynx torquilla, pheasants, quails and pigeons [see below] (Rätsch 1990).

The 'European quail' [Coturnix coturnix] is known to sometimes cause severe poisoning when eaten, and at one period in Roman history quails were believed to cause epilepsy. It has been hypothesised that quails are rendered toxic to other animals due to their diet. For example, quails are known to be able to consume hemlock seed [**Conium** maculatum] without coming to harm, yet are subsequently lethal to dogs who eat the quails. Ancient scholars claimed that quails fed on fruits of hemlock, henbane [**Hyoscyamus**] and hellebore [Helleborus spp.; see *Methods of Ingestion*, **Bufo**]. In Mauritius, 'pink pigeons' [Columba meyeri] feed on berries of 'fandamon' [an Aphloia sp. (Flacourtiaceae)], 'fangam' [a Styllingia sp. (Euphorbiaceae)] and a Lantana sp. [Verbenaceae], which have been claimed to be 'hallucinogenic'. After feeding, the birds become stupefied and incapacitated; their flesh is reputed to be 'hallucinogenic' when eaten, due to this diet. Ducks such as Anas diazi [a non-migratory Mexican duck] and A. platyrhynchos [a 'mallard'] have been observed to eat young **Bufo** toads without harm. It has been hypothesised that the Olmecs maintained their elaborate artificial lagunas at San Lorenzo in order to support duck populations which would eat **Bufo** marinus [remains of these toads were also found at the San Lorenzo site], transferring psychotropic properties to the ducks and perhaps removing the toxic properties. Duck masks of seemingly shamanic association are frequently found in Olmec archaeological remains, as are vessels and sculptures with depictions of ducks and shamans wearing duck masks. 'Cranes' have also been hypothesised as a psychotrope. The 'tsuru sennins' of Japanese lore "were 'crane-wizards' who are generally represented holding a half-gnawed crane leg and grimacing with bulging eyes and a manic ferocity". Tellingly, cranes were once the source of a valued meat even though it "did not taste good"; today it is a taboo food. Presumably, any pharmacologic effects from eating crane meat would be derived from the diet of the crane, as with other toxic birds. Cranes are generally held in rever-

ence, and in China they are associated with immortality (Kennedy 1982). The species eaten by the tsuru sennins was probably Grus japonensis, the 'Japanese crane' (pers. obs.). See also *Methods of Ingestion* for use of the 'secretary bird' Sagittarius serpentarius.

An interesting explanation has been offered for the religious veneration and magical/shamanic associations enjoyed by domestic cats in some cultures – the disease toxoplasmosis, caused by the parasite Toxoplasma gondii, which commonly infects cat intestines and is expelled in faeces. This parasite can also infect rodents, birds and humans; in rodents, the parasite so alters the behaviour of its hosts that they become attracted, rather than averse, to the smell of cat urine, and thus become easy prey for cats. In people, besides causing birth defects when pregnant women are exposed, the parasite can also affect consciousness in some people; those with weakened immune systems are more susceptible, with symptoms resembling those of schizophrenia. Incidentally, infections are common amongst schizophrenics, but can not account for all cases. The similarities of experience between 'schizophrenics' and shamans might point to a link between the mystical veneration of felines [including their supposed ubiquity as 'familiars' amongst witches] and the magical mindset, with cats – besides their other virtues – unwittingly contributing to the state of mind of their human companions, where domestic hygiene is less than ideal (Greener 2007).

Even the 'lowly' earthworm seems to have some psychoactive properties – in TCM, Pheretima aspergillam ['di-long'] is used as a sedative, hypotensive, anticonvulsant, diuretic, antipyretic and uterine stimulant (Hsu et al. 1986). Dried Lumbricus sp. earthworms and Hirudo sp. leeches, taken in wine, are reputedly aphrodisiac (Rätsch 1990). Earthworms have also been found to emit *nitrous oxide* into the soil (Matthies et al. 1998).

A USEFUL HERB TO HAVE AROUND

'Milk thistle' [Silybum marianum (Compositae)], also known as 'blessed milk thistle' or 'St. Mary's thistle', should be mentioned here not for its mental properties [even though it can treat depression], but for its useful properties as a liver tonic. The plant contains silymarin [a mixture of flavonolignans including silybin, silychristine and silydianin] concentrated mostly in the seeds, which acts as an effective agent in protecting the liver from the toxicity of 'death cap mushroom toxins' [see **Amanita**], alcohol and other drugs [including amitriptyline, nortriptyline, butyrophenone, cyclosporin, oestradiol, paracetamol, phenothiazine], hepatitis, cirrhosis, and cadmium poisoning. It is a free-radical scavenger, aids in liver regeneration, and may also have MAO-B inhibiting effects. Silymarin is not very water soluble, so the herb should be prepared as an alcohol tincture rather than as a tea. A daily dose of the seeds is 12-15g, or extracts equivalent to 200-400mg silymarin. The herb might possibly interact with warfarin, and further studies are needed to clarify this (Braun 2003; Bremness 1994; Chevallier 1996; Mazzio et al. 1998).

APPENDIX B: CHEMICAL INDEX

This appendix is intended as a guide to only some of the more interesting chemicals discussed in this book, which are distinguished in the main text by italic type. All are naturally-occurring, with the probable [but uncertain] exception of *amphetamine* and *methamphetamine*. The chemical information was obtained from The Merck Index 11th edition (Budavari et al. ed. 1989), the multi-volume Dictionary of Natural Products (Buckingham et al. ed. 1994) and The Sigma-Aldrich Library of Chemical Safety Data 2nd edition (Lenga 1988), except where other references are given. Pharmacological entries are referenced individually. The interested reader should regard this as a collection of preliminary data only. Human data for many chemicals is scarce, and much research is needed in this area.

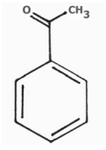
Although all practical efforts have been made to obtain complete information on chemical properties [such as melting points, solubilities etc.] with the time and resources available, this has unfortunately not been fruitful in all cases.

Abbreviations used

bp.	boiling point
dec.	decomposes
insol.	insoluble
mp.	melting point
sol.	soluble
soln.	solution

Acetophenone C_8H_8O

[1-phenylethanone; acetylbenzene; methyl phenyl ketone; hypnone]



Yellow-tinted liquid; forms laminar crystals at low temperatures; mp. 20.5°C; bp. 202°C; slightly sol. in water; freely sol. in alcohol, chloroform, ether, fatty oils, glycerol.

Soporific (Buckingham et al. ed. 1994), hypnotic. Used in perfumery to give an 'orange-blossom-like' odour [see **Citrus**] (Budavari et al. ed. 1989; Harborne & Baxter ed. 1993). Skin irritant. LD50 in rats [oral] – 815mg/kg. Keep away from flame (Lenga 1988).

In essential oils [Cistus ladaniferus, C. creticus, Stirlingia latifolia, Orthodon linalooliferum], in buds of Populus balsamifera (Harborne & Baxter ed. 1993).

Acetyl-carnitine $C_9H_{17}NO_4$

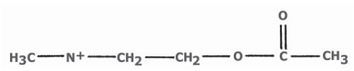
[carnitine acetyl-ester; vitamin BT acetate; 2-(acetyloxy)-3-carboxy-N,N,N-trimethyl-1-propanaminium hydroxide inner salt; (3-carboxy-2-hydroxypropyl)trimethylammonium hydroxide inner salt acetate]

Hygroscopic crystals; mp. 145°C [dec.]; very sol. in water and alcohol; practically insol. in ether.

Involved in the transport of fats into the mitochondria for energy. Long term administration [1-2g a day] can improve learning, memory and attention. Protects NMDA-receptors from degradation due to ageing (Dean & Morgenthaler 1990).

Acetylcholine $C_7H_{16}NO_2$

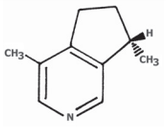
[2-acetyloxy-N,N,N-trimethylethanaminium]



The chloride form [$C_7H_{16}ClNO_2$] is a very deliquescent crystalline powder; mp. 149–152°C; normal form easily hydrolysed by alkalis.

Cholinergic and miotic agent, cardiac depressant, peripheral vasodilator. Human neurotransmitter (Buckingham et al. ed. 1994; Kruk & Pycock 1983). Can cause behavioural immobility, tranquillisation; large doses stimulate adrenal release of *epinephrine* and *norepinephrine* (Seiden & Dykstra 1977). See *Neurochemistry*.

(S)-Actinidine $C_{10}H_{13}N$

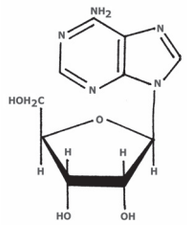


Oil; bp. 100–103°C; sol. in chloroform/methanol.

Powerful cat attractant – causes remarkable excitation in some felines (Buckingham et al. ed. 1994; Sakan et al. 1959a; Tucker & Tucker 1988). Not the same chemical as actinidin, an acidic protein also found in **Actinidia** (Harborne & Baxter ed. 1993).

Adenosine $C_{10}H_{13}N_5O_4$

[9-β-D-ribofuranosyl-9H-purin-6-amine; 9-β-D-ribofuranosyladenine; 6-amino-9-β-D-ribofuranosyl-9H-purine]

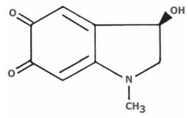


Crystals from water; mp. 234–235°C; practically insol. in alcohol.

One of the 4 principal nucleotides of nucleic acids [DNA, RNA]. Anti-arrhythmic (Budavari et al. ed. 1989), CNS- and locomotor-sedative, constricts bronchi, decreases cardiac output, dilates coronary blood vessels, modulates adenylate cyclase activity, inhibits platelet aggregation. Inhibits release of neurotransmitters, mostly acting presynaptically. Rapidly metabolised by *adenosine* deaminase; does not easily cross the blood-brain barrier (Kruk & Pycock 1983; Phillis et al. 1986; Snyder & Sklar 1984). Given to humans [i.v.], it increased blood pressure, heart rate and respiration (Biaggioni et al. 1991), the opposite of what would be expected. See *Neurochemistry*.

Adrenochrome $C_9H_9NO_3$

[2,3-dihydro-3-OH-1-methyl-1H-indole-5,6-dione; 3-OH-1-methyl-5,6-indolinedione]



Hemihydrate, brilliant red crystals from methanol and formic acid; dec. 115–120°C; freely sol. in water; fairly sol. in alcohol; almost insol. in benzene and ether. Solns. are unstable; optimum pH of water soln. 4.0. Well-formed and well-dried crystals can be kept in a vacuum dessicator for several weeks; easily oxidised to melanin. Very unstable.

Human *epinephrine* metabolite, formed by oxidation. Active sublingually 3–6mg or more; only forms from d- or dl-*epinephrine* appear to be active at these doses. Causes some LSD- or *mescaline*-like perceptual changes, and emotional depression. Visual alterations are minor at lower doses (Hoffer & Osmond 1960). Has also been found in the heart of the octopus Octopus vulgaris (Buckingham et al. ed. 1994). See *Neurochemistry*, *Influencing Endogenous Chemistry*.

Adrenocorticotropin $C_{207}H_{308}N_{56}O_{58}S$

[cotricotrophin; adrenocorticotrophin; ACTH; adrenomone]

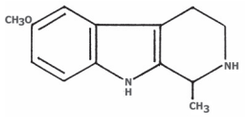
White powder; freely sol. in water; sol. in 60–70% alcohol or acetone; partly precipitates at pH 4.65–4.8; solutions are heat-stable, more stable

in acid soln.

Pituitary peptide hormone which stimulates adrenal secretions and growth of the adrenal cortex; improves learning, attention and memory. Hydrolysis products have the same activity. Used clinically for asthma and rheumatoid arthritis (Buckingham et al. ed. 1994; Budavari et al. ed. 1989; Kovacs & De Wied 1994; Kruk & Pycock 1983). See *Neurochemistry*.

Adrenoglomerulotropin $C_{13}H_{16}N_{20}$

[6-MeO-1,2,3,4-tetrahydroharman; 6-methoxytetrahydroharman; 6-MeO-THH; 1,2,3,4-tetrahydro-6-methoxy-1-methyl-β-carboline; 2,3,4,9-tetrahydro-6-methoxy-1-methyl-1H-pyrido[3,4-b]indole; 1-methylpinoline; McIsaac's compound]

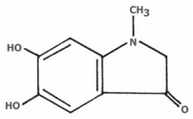


Crystals; mp. 150–151°C.

Mammalian pineal neurochemical. Some CNS activity at 100–150mg, studies lacking on higher doses; said by Claudio Naranjo to be 'hallucinogenic', though less potent than *6-methoxyharmalan* (Naranjo 1967; Shulgin & Shulgin 1997); binds to *serotonin* receptors (Glennon 1981); MAOI slightly less potent than *tetrahydroharman* in mouse brain and liver (Buckholtz & Boggan 1977). See *Neurochemistry*.

Adrenolutin $C_9H_9NO_3$

[1-methyl-1H-indole-3,5,6-triol;N-methyl-5,6-dihydroxyindoxyl; 3,5,6-trihydroxy-N-methylindole]

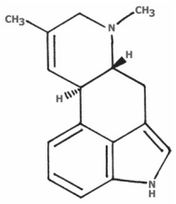


Monohydrate, bright yellow prisms from water; mp. 195/236°C [dec.]; anhydrous mp. 245°C.

Adrenochrome metabolite [along with leuco-*adrenochrome*]. Similar activity to *adrenochrome*; active sublingually 50mg (Hoffer & Osmond 1960). Potentiated by low doses of LSD or taraxein (Melander & Mårtens 1959). See *Neurochemistry*.

(-)-Agroclavine $C_{16}H_{18}N_2$

[8,9-didehydro-6,8-dimethylergoline]

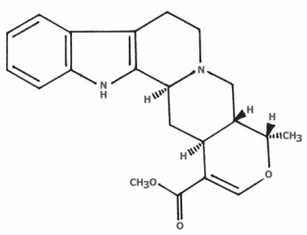


Rods from ether [dec. 198–203°C]; needles from acetone [dec. 205–206°C]; freely sol. in alcohol, chloroform, pyridine; sol. in benzene, ether; very slightly sol. in water. Mp. 208–209°C.

CNS excitant in animals, stimulating sympathetic nerves (Yui & Takeo 1958a, 1958b); hypotensive, brachycardiac, vasoconstrictor; potent *serotonin* antagonist (Takeo 1964); affects 5-HT2a receptors and α1-adrenoreceptors in the rat (Pertz 1996); also a *dopamine*-receptor agonist. Reduces uptake of *norepinephrine*, *dopamine* and *serotonin*, whilst reducing *dopamine* turnover and increasing *norepinephrine* turnover. Psychoactive in rats at 0.1-1mg/kg [s.c.] (Fuxe et al. 1978).

(-)-Ajmalicine $C_{21}H_{24}N_2O_3$

[δ-yohimbine; raubasine; vinceine; vincaine; tetrahydroserpentine; 16,17-didehydro-19-methyloxyohimban-16-carboxylic acid methyl ester]

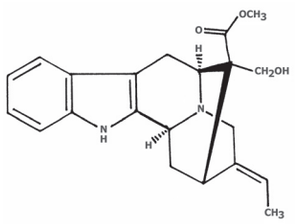


Prisms from methanol, dec. 257°C [mp. 259°C]; ajmalicine HCl – mp. 290°C [dec.], sparingly sol. in water or dilute HCl.

Vasodilator (Buckingham et al. ed. 1994), antihypertensive, tranquilliser, improves cerebral blood circulation (Budavari et al. ed. 1989; Harborne et al. ed. 1996). Blocks α1-adrenoreceptors; may also increase stimulation-induced neurotransmitter release (Creasey 1994).

Akuammidine $C_{21}H_{24}N_2O_3$

[rhazine; methyl 17-hydroxysarpagan-16-carboxylate]

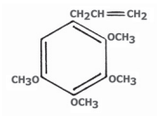


Mp. 234–236/265°C.

Hypotensive, skeletal muscle relaxant, local anaesthetic 3x more potent than *cocaine* (Harborne et al. ed. 1996).

1-Allyl-2,3,4,5-tetramethoxybenzene $C_{13}H_{18}O_4$

[1,2,3,4-tetramethoxy-5-(2-propenyl)benzene]

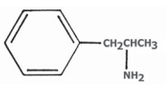


Tablets from ethanol aqueous soln.; mp. 25°C; bp. 145°C.

Non-amine precursor to TA [2,3,4,5-tetramethoxyamphetamine]; TA is psychoactive at 30-50mg or more, causing mild intoxication and mydriasis (Shulgin & Shulgin 1991; Shulgin et al. 1967).

Amphetamine $C_9H_{13}N$

[racemic desoxy-nor-ephedrine; β-aminopropylbenzene; (+-)-α-methylbenzene ethanamine; dl-α-methyl-phenethylamine; 1-phenyl-2-aminopropane; (phenylisopropyl)amine]



Mobile liquid with amine odour and burning, acrid taste; volatilises slowly at room temp.; bp. 82–85/200–203°C; slightly sol. in water; sol. in alcohol, ether; readily sol. in acids. Aqueous solns. are alkaline. *Amphetamine* sulphate is also known as benzedrine.

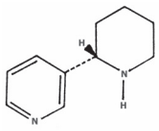
CNS stimulant and excitant, anorexic, antifatigue, sympathomimetic, bronchodilator, mydriatic. Excessive use may result in insomnia, headache, hyperirritability, anxiety, tachycardia, perspiration, fever, weakness, hypertension and/or hypotension, and even psychosis. The d-isomer is 3–4x as potent as the l-isomer in eliciting CNS effects; the l-isomer is slightly more potent than the d-isomer in affecting cardiovascular activity (Beckman 1961; Budavari et al. ed. 1989; Goodman & Gilman 1975; Julien 1995). Causes *norepinephrine* [most potently] and *dopamine* release, and blocks their re-uptake (Rothman et al. 2001; Julien 1995). Ligand of the trace amine [TA] receptor (Jacob & Presti 2005). Stimulates hydrox-

yindole-O-methyltransferase [HIOMT] activity in bovine pineal (Hartley & Smith 1973). Locomotor and psychostimulant activity may be at least partially mediated by endogenous CART peptides [see *Neurochemistry*] (Kimmel et al. 2000). Medicinal dose 5–10mg (Beckman 1961); moderate psychoactive dose 20–50mg [orally or snuffed], though some people experience 'severe reactions' from as little as 20–30mg; some i.v. users of the drug [with an established tolerance] may inject 100–500mg at a time (Julien 1995). Should not be taken within 2 weeks of taking MAOIs or tricyclic antidepressants; should not be taken by people with high blood pressure, heart disease, anorexia, hyperthyroidism, glaucoma, depression, schizophrenia or paranoid psychosis (Upfal 1995). LD50 in rats – 180mg/kg [s.c.]; LD50 of *amphetamine* sulphate in mice [oral] – 24.2mg/kg, and rats [oral] – 55mg/kg (Budavari et al. ed. 1989).

Widely used by soldiers from both sides in World War II (Julien 1995), and still used by some military personnel the world over. Controlled substance.

Anabasine $C_{10}H_{14}N_2$

[neo-nicotine; nicotimine; (S)-3-(2-piperidinyl)pyridine; 2-(3-pyridyl)piperidine]

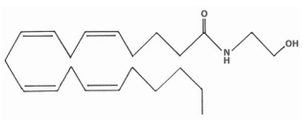


Liquid; mp. 25-30°C; bp. 104-105/145-147/270-272/276°C; sol. in water and most organic solvents.

Similar to *nicotine* in action, though less potent; binds to nicotinic *acetylcholine*-receptors (Sloan et al. 1988). Subacute and acute poisoning can cause vertigo, confusion, disturbed vision and hearing, photophobia, increased salivation, nausea, vomiting, cold extremities, diarrhoea, fainting and clonic spasms. Highly toxic, teratogenic, insecticidal. Also found in Anabasis aphylla (Buckingham et al. ed. 1994; Budavari et al. ed. 1989).

Anandamide $C_{22}H_{37}NO_2$

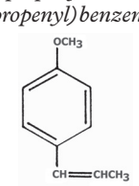
[arachidonylethanolamide; 5,8,11,14-eicosatetraenoic acid-(2-hydroxyethyl)amide]



Cannabinoid receptor ligand; produces effects similar, but not wholly identical to, those of *THC* (Wiley 1999); acts as a partial agonist, and antagonises binding of *THC* (Fride et al. 1995); also agonist of vanilloid VR1 capsaicin receptors (Szolcsányi 2000). Modulates pain (Piomelli et al. 2000; Walker et al. 1999); stimulates release of dynorphins A and B, as well as leu-*enkephalin*, in spinal cord (Houser et al. 2000). Ameliorates some symptoms of Multiple Sclerosis in experimental studies (Baker 2000; Di Marzo et al. 2000); inhibits binding to brain muscarinic *acetylcholine* receptors (Lagalwar et al. 1999); inhibits *glutamine* transmission (Piomelli et al. 2000); protects cortical neurons from ischaemic damage (Sinor et al. 2000). The structurally-related essential fatty acid (Z)-5,8,11,14-eicosatetraenoic acid is a constituent of many animal phospholipids, and also occurs in some ferns and mosses – it is potentially explosive (Buckingham et al. ed. 1994). See *Neurochemistry*.

Anethole $C_{10}H_{12}O$

[anise camphor; p-propenylanisole; 1-methoxy-4-(1-propenyl)benzene]

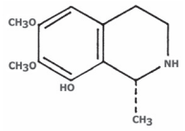


Leaflets with a sweet taste from ethanol at 20–21°C; mp. 21.4–22.5°C; bp. 235°C. Practically insol. in water; miscible with ether, chloroform; sol. in benzene, ethyl acetate, acetone, petroleum ether, alcohol.

Spasmolytic, carminative, may stimulate liver regeneration. Blocks neuromuscular transmission, may have some anticholinergic activity. Moderately toxic; LD50 in rats [i.p.] – 900mg/kg; the cis-isomer is more toxic, with an LD50 in rats [i.p.] of 93mg/kg (Albuquerque et al. 1995; Budavari et al. ed. 1989; Harborne et al. ed. 1996). Pheromone in some 'corn rootworms' [Diabrotica undecimpunctata, D. virgifera; see *estragole*] (Buckingham et al. ed. 1994). Non-amine precursor to 4-MA [PMA; 4-methoxyamphetamine], which is active at 50-80mg, causing an intoxicated state with mild psychedelic effects; raises blood pressure. Lasts c.5hrs (Shulgin 1973; Shulgin & Shulgin 1991). One underground chemist who synthesised a batch from 'essence of aniseed' described the drug: "It was totally disastrous because nobody liked it except us. It was sort of like psychedelic methedrine [*methamphetamine* HCl] [...] Very, very speedy [...] We took it ourselves and we got well crazy on it. It made you into a Viking berserker. We were roaming around mountains wild-eyed with sweat popping out [...] when you actually shot it up the rush made everything go black and white and the sky went like the set from a Wagner opera and you had this certainty that you were about to die but you didn't care. That didn't exactly endear it to the punters at Notting Hill Gate" (Ezra Pence [pseudonym], in Green ed. 1988)! 4-MA is a controlled substance, and higher doses [hundreds of mgs] have been fatal. It has often been encountered in the illicit drug trade, misrepresented as 'ecstasy' [3,4-methylenedioxy-*methamphetamine*] (pers. comms.).

Anhalonidine $C_{12}H_{17}NO_3$

[1,2,3,4-tetrahydro-8-hydroxy-6,7-dimethoxy-1-methylisoquinoline]



Small octahedra from benzene, mp. 160–161°C; freely sol. in water, alcohol, chloroform, hot benzene; sparingly sol. in ether; solutions acquire a reddish colour on standing.

Highly toxic; narcotic and curarising to frogs, but apparently not to mammals. Sedative in humans at 100–250mg, claimed by Lewin to be hallucinogenic (Kapadia & Fayez 1970; Kloesel 1958; Shulgin 1973).

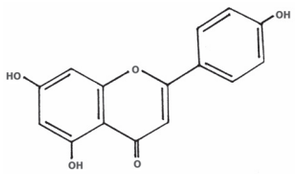
Apamin $C_{79}H_{13}N_{31}O_{24}S_4$

White powder with grey-tan cast.

Smallest neurotoxic polypeptide known. CNS excitant; interacts with spinal cord, causing spasms and convulsions; highly toxic (Buckingham et al. ed. 1994; Budavari et al. ed. 1989; Lenga 1988). Antagonises Ca2+-activated K+ ion channels (Kebadian & Neumeyer ed. 1994); blocks some 'high-affinity LSD-binding sites' (Lyttle 1993), presumably *serotonin* receptor subtypes (pers. obs.). Activity destroyed by oxidation with performic acid. LD50 in mice [i.v.] – 4mg/kg (Budavari et al. ed. 1989). In honey bee venom [see *Endnotes*] (Buckingham et al. ed. 1994).

Apigenin $C_{15}H_{10}O_5$

[4',5,7-trihydroxyflavone; 5,7-dihydroxy-2-(4-hydroxyphenyl)-4H-1-benzopyran-4-one; 2-(p-hydroxyphenyl)-5,7-dihydroxychromone]

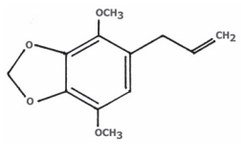


Yellow needles from aqueous pyridine; mp. 345–352°C; practically insol. in water; moderately sol. in hot alcohol; sol. in ethanol, methanol, dilute potassium hydroxide. Found free or as glycosides.

Anxiolytic and mild sedative agent. Binds to BZ receptors (Viola et al. 1995); inhibited MAO, type A more strongly than B (Han et al. 2007; Sloley et al. 2000).

Apiole $C_{12}H_{14}O_4$

[parsley camphor; 2,5-dimethoxy-3,4-methylenedioxy-1-allylbenzene]

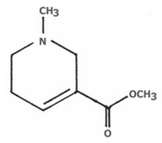


Crystals with faint parsley odour; mp. 29.5°C; bp. 294°C; insol. in water; sol. in alcohol, chloroform, benzene, ether, acetone, oils.

In high doses may cause short-lived intoxication. Insecticidal spasmolytic (Harborne et al. ed. 1996), abortifacient. Ingestion of 1g has caused death in a human. Symptoms of toxicity include strong abdominal pain, vomiting, diarrhoea, fever and vaginal bleeding. In essential oils (Battaglia 1995). Precursor to DMMDA [2,5-dimethoxy-3,4-methylenedioxy-*amphetamine*], which is mildly psychedelic at 75mg, lasting 6-8hrs (Shulgin 1973; Shulgin & Shulgin 1991), and is a controlled substance.

Arecoline $C_8H_{13}NO_2$

[arecaidine methyl ester; 1,2,5,6-tetrahydro-1-methyl-3-pyridinecarboxylic acid methyl ester; methyl 1,2,5,6-tetrahydro-1-methylnicotinate]

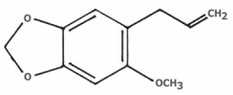


Oily liquid; bp. 92–94/105/209°C. Volatile with steam. Miscible with water, alcohol, ether; sol. in chloroform.

Cholinergic stimulant [muscarinic *acetylcholine* receptor agonist] in low doses, parasympathetic depressant in high doses, cathartic, brachycardiac, hypotensive, miotic, diaphoretic, vermifuge, increases tone of intestinal muscle (Bavappa et al. 1982; Marshall 1987); enhances serial learning (Sitaram et al. 1978). Toxic, possibly carcinogenic (Buckingham et al. ed. 1994). LD50 in mice and dogs – 100mg/kg, 5mg/kg s.c. (Budavari et al. ed. 1989).

Asaricin $C_{11}H_{12}O_3$

[5-methoxy-6-(2-propenyl)-1,3-benzodioxole; 1-allyl-2-methoxy-4,5-methylendioxybenzene; 2-allyl-4,5-methylenedioxyanisole ; has been called 'sarisan']

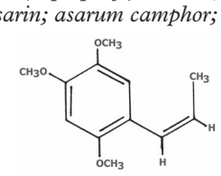


Oil; bp. 99°C. Virtually identical to *carpacin*.

Antifungal, insecticidal (Buckingham et al. ed. 1994). Non-amine precursor to MMDA-2 [2-methoxy-4,5-methylenedioxy-*amphetamine*], which is active at 25–50mg, lasting 8–12hrs – enhances awareness, similar to MDA [see *safrole*] (Shulgin 1973; Shulgin & Shulgin 1991), and is a controlled substance.

Asarone $C_{12}H_{16}O_3$

[1,2,4-trimethoxy-5-(1-propenyl)benzene; 2,4,5-trimethoxy-1-propenylbenzene; asarin; asarum camphor; asarabacca camphor]

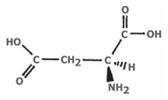


Occurs as a mixture of two isomeric forms [α-, the (E)- or trans-isomer, and β-, the (Z)- or cis-isomer (shown)]. α-Asarone – needles from light petroleum; mp. 62–62°C; bp. 296°C. Practically insol. in water; sol. in alcohol, ether, glacial acetic acid, chloroform, petroleum ether.

Sedative similar to *reserpine* (Sharma et al. 1961), spasmolytic, hypocholesterolaemic, anti-algal. Attractant, antifeedant and chemosterilant in insects. In animals, *asarone* prolongs the hypnotic activity of anaesthetics, acts as a cardiac depressant and hypotensive, and has some anticholinergic activity. The sedative action is apparently due to depression of the ergotropic division of the hypothalamus. Others observed it to cause excitation followed by sedation (Buckingham et al. ed. 1994; Hall 1973; Oswald et al. 1971b; Rastogi & Mehrotra ed. 1990-1993). In mice, β-*asarone* is more potent than α-*asarone* (Sharma et al. 1961); may be toxic, believed to be carcinogenic in high doses or with extended exposure (Harborne & Baxter ed. 1993; Lopez, M.L. et al. 1993). Non-amine precursor to TMA-2 [2,3,5-trimethoxy-*amphetamine*], which is active at 20-40mg or more, lasting 8-12hrs – similar to *mescaline*, but less colourful visually. Can cause nausea and brief periods of amnesia (Shulgin 1973, 1976; Shulgin & Shulgin 1991). TMA-2 is a controlled substance.

Aspartic acid $C_4H_7NO_4$

[aspartate; aminobutanedioic acid; aminosuccinic acid; asparagic acid; asparaginic acid]

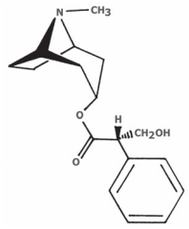


Leaflets from water; mp. 269–271°C.

Excitatory amino acid (Kruk & Pycock 1983). (S)-form found in proteins, peptides, sugar cane and sugar beet molasses; (R)-form in the red alga Chondria armata (Buckingham et al. ed. 1994). See *Neurochemistry*.

Atropine $C_{17}H_{23}NO_3$

[dl-tropine tropate; dl-hyoscyamine; 1-α-H,-5-α-H-tropan-3-α-ol-dl-tropate]

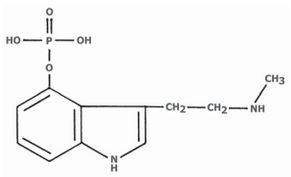


Long orthorhombic prisms from acetone, mp. 114–117°C. Slightly sol. in water; freely sol. in alcohol, glycerol, ether, chloroform; sol. in benzene and dilute acids.

Atropine is racemised during extraction from plant matter, to a mixture of equal parts d-*hyoscyamine* and l-*hyoscyamine*. Potent *acetylcholine*-inhibitor [blocks muscarinic receptors]; can reduce response to *histamine*, *norepinephrine* and *serotonin*. Causes excitement, agitation, delirium, blurred vision, difficulty in swallowing or speaking, suppressed salivation, dried mucous membranes, vasodilation, bronchodilation [large doses depress respiration], fever, muscular relaxation and mydriasis. Large doses lead to depression, tachycardia, coma, and death from paralysis of the medulla. Action is more prolonged than that of *hyoscine*, and comparitively has a stronger action on heart, intestine and bronchial muscle. Used in anaesthesia and anticholinesterase poisoning, as well as to treat some symptoms of Parkinson's Disease, and to produce mydriasis for optical examination. Hallucinogenic over 5-10mg; used therapeutically 0.2-1mg; lethal dose in humans uncertain – doses of 1000mg have been survived, yet 10mg has been lethal in a child. Can be absorbed through the skin (Beckman 1961; Buckingham et al. ed. 1994; Budavari et al. ed. 1989; Goodman & Gilman 1975; Henry 1939). Has been shown to weakly inhibit MAO and *5-hydroxytryptophan* decarboxylase (Rastogi & Mehrotra ed. 1990-1993).

Baeocystin $C_{11}H_{15}N_2O_4P$

[baeocystine; 4-phosphoryloxy-N-methyltryptamine]

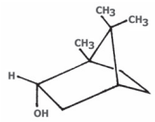


Sol. in methanol; mp. 245-248/254-258°C.

Precursor to *psilocybin*. Psychedelic. Gartz noted that 4mg "caused mild hallucinations for three hours", with 10mg "about as psychoactive as a similar amount of *psilocybin*" (Gartz 1989a, 1996).

D-Borneol $C_{10}H_{18}O$

[(+)-borneol; (+)-bornylalcohol; borneo camphor; (1S,2S)-2-bornanol]

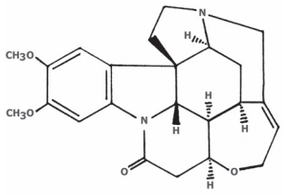


White hexagonal plates from petroleum ether; mp. 206–208°C; peculiar peppery odour and burning taste resembling that of mint; almost insol. in water; sol. in alcohol, ether, petroleum ether, benzene, toluene, acetone.

Can cause dizziness, mental confusion, nausea, vomiting, headaches, irritation and convulsions. LD50 in rabbits [oral] – 2g/kg (Budavari et al. ed. 1989; Lenga 1988).

Brucine $C_{23}H_{26}N_2O_4$

[10,11-dimethoxy-strychnine; 2,3-dimethoxystrychnidin-10-one]

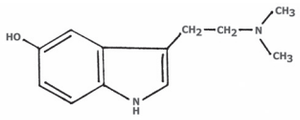


Needles from acetone/water, mp. 178°C; sol. in methanol, alcohol, chloroform, ethyl acetate, glycerol; slightly sol. in benzene, ether, boiling water. Handle in hood only.

CNS stimulant similar to *strychnine*; lethal dose to humans c.200mg (Harborne et al. ed. 1996).

Bufotenine $C_{12}H_{16}N_2O$

[5-hydroxy-N,N-dimethyltryptamine; 5-OH-DMT; N,N-dimethylserotonin; mappin; 3-[2-(dimethylamino)ethyl]-1H-indol-5-ol]

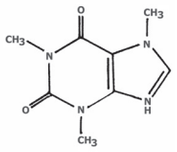


Prisms from ethyl acetate, mp. 146–147°C; methyliodide prisms from methanol, mp. 214–215°C; practically insol. in water; sol. in alcohol, dilute acids.

Psychoactive at 8-15mg i.v. or i.m. [not the preferred routes, as they are more likely to manifest excessive peripheral side-effects, which are typical symptoms of *serotonin* syndrome]. The oxalate was inactive nasally at up to 16mg, and the creatinine sulphate is also of questionable nasal activity, though the freebase was active from 6-10mg by this route. Effects from i.v. and/or i.m. administration include raised blood pressure, anxiety, apprehension, constriction or oppression of the chest, abdominal cramps, sweating, facial flushing [sometimes becoming purplish or cyan in some high-dose i.v. experiments] and vasoconstriction. Blobby, coloured or black and white visual effects ["pseudo-hallucinations of colour"], as well as mental overactivity and feelings of unreality were noted. An i.v. dose of 10mg over 50 seconds in a schizophrenic patient caused EEG readings to fall to 0.5-1Hz after 5 minutes. Death has occurred when taken with *reserpine* (Fabing & Hawkins 1956; McLeod & Sitaram 1985; Ott 2001a; Turner & Merlis 1959; Wassén & Holmstedt 1963). Recent bioassays conducted by Jonathan Ott [and in some cases, associates] indicate the freebase to be active intranasally from 5mg, with a visionary threshold at 40mg; similar observations were made for the sublingual route. Co-administration of very low doses of *harmine* and/or *harmaline* [eg. 7.5mg *harmine*] via these routes enabled equivalent activity from half the usual dose of *bufotenine*. [It should be noted that Ott is a low-MAO phenotype and thus these MAOI doses may be quite different for others.] Oral activity was observed above 100mg, though when taken with 40mg *harmaline*, Ott experienced a similar level of effect from only 20mg *bufotenine* freebase. Active from 2-8mg vapourised. Intrarectally, 30mg [with 250mg sodium bicarbonate and 1g cocoa butter] produced only physical effects; threshold psychoactivity was noted when the same dose was combined with 10mg *harmaline*. Onset and duration were similar to that observed with *5-methoxy-DMT* by the same routes. Effects of the freebase via these routes included euphoria [or dysphoria for some]; perception of a high-pitched tone [as with other entheogenic tryptamines such as *DMT*]; and subtle visionary effects from behind closed eyes, or overlaid onto the surroundings and best appreciated in dim light rather than darkness (Ott 2001a). Has shown MAOI activity in vitro, less potent than that of *DMT* or *5-methoxy-DMT* (Ho et al. 1970). Strong agonist of 5-HT1a, 5-HT1b, 5-HT1c & 5-HT2a receptors; less potent agonist of 5-HT1d & 5-HT2b receptors (McKenna et al. 1990; Peroutka 1986, 1993). More potent in the brain than *5-methoxy-DMT*, but less potent overall due to its increased difficulty in crossing the blood-brain barrier (McBride 2000). Mammalian neurochemical (Corbett et al. 1978; Cottrell et al. 1977; Tanimukai et al. 1970) – see *Neurochemistry*. Controlled substance in the US and Australia.

Caffeine $C_8H_{10}N_4O_2$

[theine; guaranine; methyltheobromine; 1,3,7-trimethylxanthine]



Hexagonal prisms by sublimation, mp. 238°C; sublimes 178°C. Aqueous solutions of caffeine salts dissociate quickly. Sol. in water, alcohol, acetone, chloroform, ether, benzene, ethyl acetate; slightly sol. in petroleum ether.

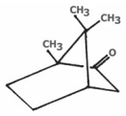
CNS, cardiac, and weak respiratory stimulant; diuretic; increases muscle irritability. Blocks *adenosine* receptors, removing their inhibition of *dopamine* release; weak phosphodiesterase inhibitor, increasing cAMP levels and potentiating β-adrenergic stimulation, though at levels much higher than those achieved naturally; BZ-receptor antagonist (Biaggioni et al. 1991; Budavari et al. ed. 1989; Garrett & Holtzman 1994; Goodman & Gilman 1975; Kruk & Pycock 1983; McManamy & Schube 1936; Saano & Airaksinen 1982; Snyder & Sklar 1984); antagonises respiratory depression induced by *codeine* or *morphine* (Bellville et al. 1962). Respiratory-stimulant effects are thought to be more closely linked to the type-4 phosphodiesterase-inhibition of *caffeine*, rather than *adenosine*-antagonism, as had previously been presumed; the CNS-stimulant effects are still believed to be mediated by antagonism at *adenosine* receptors (Howell 1993). Active in CNS as a stimulant at 100-200mg or more; excessive use may result in insomnia, agitation, anxiety, tremors, arrhythmia, vertigo, headache, muscle stiffness (Goodman & Gilman 1975; Julien 1995; McManamy & Schube 1936; Snyder & Sklar 1984), perspiration, nausea, abdominal cramps and indistinct hallucinations (pers. obs.). Heavy users experience less insomnia from *caffeine* taken before going to bed. Chronic consumption causes an up-regulation and/or sensitisation of platelet *adenosine* receptors. Addictive; withdrawal symptoms may include dysphoria, irritability, nervousness, difficulty in concentrating, lethargy and headache. Low doses can improve task performance, whilst higher doses impair it; however, performance enhancement is most noticeable only in people who were previously fatigued, rather than those who were well-rested (Biaggioni et al. 1991; Goldstein & Kaizer 1969; Snyder & Sklar 1984). Has been used as a *cocaine* substitute (Siegel 1980), and in the Philippines, has been smoked with *ephedrine*, the mixture being called 'shabu'; its use there today has been superceded by smokeable *methamphetamine*, sometimes known as 'ice' (Karch 1996) [and also known as shabu in Japan] (Julien 1995). *Caffeine* taken as strong, freshly-brewed coffee [see **Coffea**] after the onset of the peak of a *mescaline* or *psilocybin* experience, has been observed to "maximise both rushing sensations and perceptual disturbances"; this effect was most noted with *psilocybin* (Trout & Friends 1999). LD50 in mice [oral] – 127-137 mg/kg (Budavari et al. ed. 1989); human LD 192 mg/kg [oral] (Lenga 1988) or around 10g; symptoms of toxicity are expected at 1g and above (Goodman & Gilman 1975).

Paraxanthine [1,7-dimethylxanthine], the main metabolite of *caffeine*, is also an effective *adenosine* receptor antagonist, as is the main metabolite of paraxanthine, 1-methylxanthine (Biaggioni et al. 1991; Snyder & Sklar 1984).

Also found in Bidens pilosa [0.00025% in aerial parts], Cereus jamacaru [0.08–0.11% in seeds; may be in error], Combretum spp., Erodium cicutarium ['stork's bill'], Firmiana simplex ['wu tong'], Harrisia adscendens [0.12–0.2% in seeds; may be in error], Leocereus bahiensis [0.1-0.35% in seeds; may be in error], Neea therifera and Pilocereus gounellei [0.15–0.22% in seeds; may be in error] (Huang 1993; Rätsch 1998; Sarker et al. 2000; Suzuki et al. 1992; Trout ed. 1999).

Camphor $C_{10}H_{16}O$

[2-camphanone; 1,7,7-trimethylbicyclo[2.2.1]-heptan-2-one]

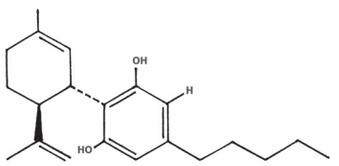


Translucent mass with crystalline fracture; rhombohedral crystals from alcohol; sublimes appreciably at room temp.; very steam volatile; mp. 179°C; bp. 204°C. Sparingly sol. in water; sol. in petroleum ether, fixed and volatile oils, alcohol, ether, chloroform, benzene, acetone, glacial acetic acid.

Can cause CNS-stimulation and euphoria, vertigo, mental confusion and delirium. Clonic convulsions, coma, respiratory failure and death may occur from doses of 730mg/kg or higher (Hall et al. 1978a; Karch 1996; Lenga 1988; McManamy & Schube 1936). Irritant, analeptic, respiratory stimulant, topical analgesic, antipruritic, antiinfective, antirheumatic. LD50 in mice [i.p.] – 3g/kg (Buckingham et al. ed. 1994; Budavari et al. ed. 1989; Lenga 1988).

Cannabidiol $C_{21}H_{30}O_2$

[CBD]

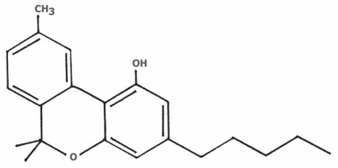


Pale yellow resin or crystals from petroleum ether; mp. 66–67°C; bp. 130/160–180/187–190°C. Practically insol. in water; sol. in alcohol, ether, benzene, chloroform, petroleum ether.

Sedative, analgesic, antibiotic, antiepileptic; seems to potentiate the depressant and antagonise the excitatory effects of Δ-9 *THC*; delays onset of high, prolongs duration and increases intensity (Hollister & Gillespie 1975; Karniol & Carlini 1973; Mechoulam 1970; Zuardi et al. 1982). Potent antioxidant; can protect against neuronal damage (Aesoph 1998; Hampson et al. 1998). Slightly suppresses MAO activity (Coper 1982).

Cannabinol $C_{21}H_{26}O_2$

[CBN; 6,6,9-trimethyl-3-pentyl-6H-dibenzo[b,d]pyran-1-ol]

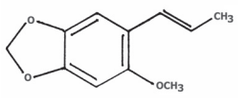


Faint orange resin or leaflets from petroleum ether; mp. 76–77°C; bp. 185°C. Sol. in alcohol, aqueous alkaline solutions.

The oxidative degradation product of *THC*. Has about 1/10 of its psychoactive potency [otherwise stated to be non-psychoactive]; seems to potentiate the disorientating qualities of *THC* whilst blocking its other effects (Hollister & Gillespie 1975; Karniol et al. 1975).

Carpacin $C_{11}H_{12}O_3$

[isosafrole methyl ether; 2-methoxy-4,5-methylenedioxy-1-propenylbenzene; 5-methoxy-6-(1-propenyl)-1,3-benzodioxole; 1-allyl-2-methoxy-4,5-methylenedioxybenzene; 2-allyl-4,5-methylenedioxyanisole; has been called 'sarisan' incorrectly]

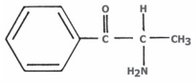


Crystals or oil from petroleum ether; mp. 47°C; bp. 119–124°C.

Non-amine precursor to MMDA-2 [see *asaricin*] (Shulgin & Shulgin 1991).

Cathinone $C_9H_{11}NO$

[α-aminopropiophenone; α-benzoylethylamine; 2-amino-1-phenyl-1-propanone]

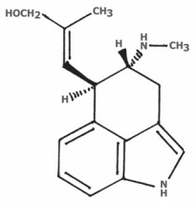


Sol. in methanol [with racemisation], methylene chloride; HCl mp. 189–190°C. Unstable except in dilute non-polar non-hydroxylic soln. Transformed in unfresh leaves of **Catha** edulis to *norpseudoephedrine* and norephedrine, with other minor breakdown byproducts [see **Catha**].

CNS stimulant similar to *amphetamine*, but more pleasurable; 8x more potent in causing *dopamine*-release than *norepinephrine*-release. Binds to *serotonin* receptors, though the dl-form is weaker in this regard; the d-form does not bind to these receptors. Also causes hyperthermia, respiratory stimulation, mydriasis, arrhythmia, hypertension and anorexia (Bruneton 1995; Crombie et al. 1990; Glennon & Liebowitz 1982; Kalix 1991).

Chanoclavine $C_{16}H_{20}N_2O$

[chanoclavine I; secaclavine]

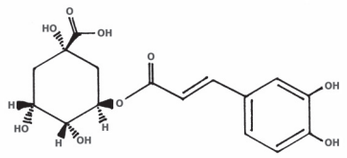


Thick prisms and polyhedra from acetone or methanol; mp. 220–222°C; sol. in boiling chloroform, boiling acetone, boiling ethyl acetate, boiling methanol; practically insol. in water.

Not thought to be active (Hofmann 1963), but has been claimed [perhaps in error] to be hallucinogenic (Harborne & Baxter ed. 1993). Found in various fungi and Convolvulaceae; mould fungi not mentioned elsewhere in this book yielding *chanoclavine* include Corticum caeruleum, Lenzites trabea and Pellicularia filamentosa (Abe et al. 1969).

Chlorogenic acid $C_{16}H_{18}O_9$

[caffetannic acid; caffeylquinic acid; helianthic acid; 3-O-caffeoylquinic acid; 3-(3,4-dihydroxycinnamoyl)quinic acid]

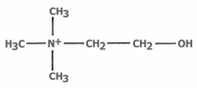


Hemihydrate, needles from water. Becomes anhydrous at 110°C; mp. 208°C. Freely sol. in alcohol, acetone; slightly sol. in water, much more so in hot water. Alkaline solns. turn orange. Forms caffeic acid on hydrolysis. First isolated from Liberian coffee [see **Coffea**]; found in many plants.

Antioxidant, anticarcinogenic, antimutagenic, inhibits cytochrome P450, inhibits glial MAO-B in rats (Mazzio et al. 1998; Shahrzad & Bitsch 1996; Yamada & Tomita 1996). Claimed to have "sexually stimulating effects" (Rätsch 1990). See also **Alstonia**.

Choline $C_5H_{14}NO+$

[bilineurine; sinkalin; amanitin; araquine; arachine; trimethylethanolamine; 2-hydroxy-N,N,N-trimethylethanaminium; (2-hydroxyethyl)-trimethylammonium]

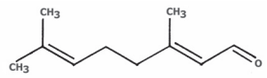


Hazy yellow substance; air and light sensitive; handle with care, as can cause burns. Destructive to tissue when inhaled (Lenga 1988).

Constituent of lecithin [phosphatidylcholine], which gives free *choline* on hydrolysis; lipotropic. Precursor to endogenous *acetylcholine*, with similar effects, but much less active; when not acting as a precursor to *acetylcholine*, probably stimulates *acetylcholine* release and acts as an agonist of muscarinic *acetylcholine* receptors. Poorly absorbed from the gastrointestinal tract, and is partly converted to trimethylamine and its oxide by

intestinal bacteria; converted to betaine, phosphorylcholine and lipids in the kidney. Thus, dietary *choline* rarely reaches the brain in quantity and has only weak peripheral activity due to its fairly rapid breakdown [this may be where *2-dimethylaminoethanol* comes in – see below]. When not obtained from dietary sources, can be biosynthesised endogenously from l-serine. Can act as a methyl-donor [eg. see *methionine*], such as in the biosynthesis of *methionine* from homocysteine; conversely, *methionine* from S-adenosylmethionine [SAM] acts as a methyl donor in the biosynthesis of *choline*. Reputed to improve memory and intelligence (Buckingham et al. ed. 1994; Dean & Morgenthaler 1990; Goodman & Gilman 1975; Haubrich et al. 1981; Sitaram et al. 1978; Tucek 1988). Pre-administration of phosphatidylcholine for several days prior to ingestion of "psychotropics including *mescaline* and especially *DMT*" has been observed to "enrich" the content of the experience (Trout & Friends 1999). LD50 in rats [oral] – 6640mg/kg (Lenga 1988). Estimated human LD50 [oral] – 200-400g. Oral doses of 10g produced no obvious effects (Goodman & Gilman 1975). See *Neurochemistry*.

Citral $C_{10}H_{16}O$

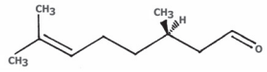


Natural citral is a mix of 2 geometric isomers, geranial [trans-citral, or citral A (shown)] and neral [cis-citral, or citral B]. Geranial is a light oily liquid with a strong lemon odour [see **Citrus**]; bp. 92–93°C; practically insol. in water; miscible with alcohol, ether, glycerol, mineral oil, essential oils. Neral is a light oily liquid with a lemon odour [less intense, but sweeter than geranial]; bp. 91-92°C. Solubility same as geranial. Not stable to alkalis or strong acids.

It is the sex pheromone of the parasitic wasp Itoplectis conquisitor (Buckingham et al. ed. 1994). When isolated from plants as the geometric isomer geranial, it may be condensed with olivetol to form Δ-9 *THC*; alternately, verbenol may be used in place of geranial, resulting in Δ-6 *THC* (Mechoulam et al. 1972).

Citronellal $C_{10}H_{18}O$

[rhodinal; 3,7-dimethyl-6-octenal]

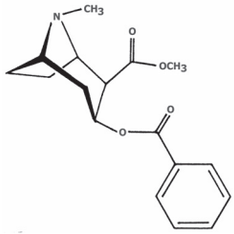


Colourless liquid; bp. 204–205°C. Sol. in alcohols; very slightly sol. in water.

Sedative, antiseptic, insect-repellant (Budavari et al. ed. 1989; Harborne et al. ed. 1996); may cause irritation (Lenga 1988).

Cocaine $C_{17}H_{21}NO_4$

[ecgonine methyl ester benzoate; benzoyl ecgonine methyl ester]

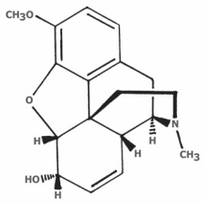


Monocline octahedra from alcohol, mp. 98°C. Volatile, esp. above 90°C; bp. 187–188°C. Slightly sol. in water; freely sol. in alcohol, ether, chloroform, petroleum, olive oil; sol. in acetone, ethyl acetate and carbon disulfide.

Potent CNS stimulant and euphoriant, adrenergic blocker, topical anaesthetic, vasoconstrictor, mydriatic. Inhibits *norepinephrine*, *dopamine* and *serotonin* re-uptake. Locomotor and psychostimulant activity may be at least partially mediated by endogenous CART peptides [see *Neurochemistry*]. Active 25-150mg; 20mg has been fatal or severely toxic, but only in very rare cases of individual sensitivity. Death may be due to respiratory depression, arrhythmia, seizures and/or severe hypertension (Buckingham et al. ed. 1994; Goodman & Gilman 1975; Julien 1995; Katzung & Trevor 1995; Kennedy 1985; Kimmel et al. 2000; Platt 1997). LD50 in rats [i.v.] – 17.5mg/kg (Budavari et al. ed. 1989). See **Erythroxylum** for further discussion of side effects. Controlled substance.

Codeine $C_{18}H_{21}NO_3$

[3-O-methyl-morphine; 7,8-didehydro-4,5-epoxy-3-methoxy-17-methylmorphinan-6-ol]

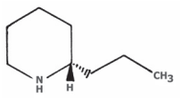


Orthorhombic sphenoidal rods or octahedra from water or dilute alcohol; mp. 154–156°C; slightly sol. in water, freely sol. in alcohol and dilute acids.

Narcotic, analgesic, antitussive, spasmolytic. Can cause nausea, dizziness, headache, CNS stimulation, convulsions, cyanosis, constipation, drowsiness and respiratory depression. Opiate receptor-agonist; c.0.1-0.25x as potent as *morphine*. Induces *histamine* release. Active 30-400mg. Can cause itching, flushing, dizziness, sedation, nausea and vomiting above 250mg. LD50 in rats – 427mg/kg [oral] (Buckingham et al. ed. 1994; Chahl 1991; Harborne et al. ed. 1996; Lenga 1988; Noyez et al. 1975; Preininger 1975; pers. comms.). Endogenous mammalian neurochemical (Cardinale et al. 1987; Noyes et al. 1975). Controlled substance.

Coniine $C_8H_{17}N$

[S-2-propylpiperidine; cicutine; conicine; N-methylconine; pseudoconhydrine]

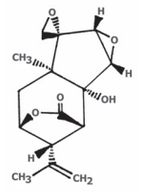


Colourless alkaline liquid, darkens and polymerises on exposure to light and air; mousy odour; mp. -2°C; bp. 65–66/166–166.5°C. Volatile with steam. Sol. in water [less so in hot water], alcohol, ether, acetone, benzene; slightly sol. in chloroform.

CNS excitant, then depressant. Causes weakness, drowsiness, nausea, vomiting, salivation, laboured respiration, increasing weakness, paralysis of CNS and skeletal muscle nerve endings, asphyxia, and eventually death. Estimated toxic dose 60mg; estimated lethal dose 100-300mg. LD50 in mice [oral] 100mg/kg. Also found in 'dog parsley', Aethusa cynapium (Budavari et al. ed. 1989; Wexter ed. 1998) and in Sarracenia flava (Mody et al. 1976).

Coriamyrtin $C_{15}H_{18}O_5$

[coriamyrtione]

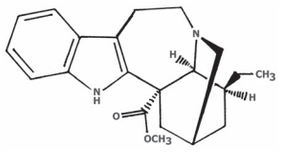


Bitter, monoclinic prisms; mp. 229-230°C. Slightly sol. in water, alcohol; freely sol. in ether, and hot alcohol.

Causes extreme CNS-excitation (Lenga 1988). LD50 in mice [i.p.] – 3mg/kg (Budavari et al. ed. 1989).

Coronaridine $C_{21}H_{26}N_2O_2$

[carbomethoxyibogamine]



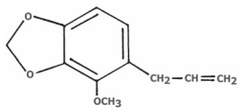
Amorphous crystals; mp. 235°C; sol. in methanol, ethanol, benzene.

CNS stimulant 25 times less potent than *ibogaine* (Bert et al. 1988). Analgesic, surface anaesthetic, hypothermic, diuretic, weakly oestrogenic, muscle relaxant, hypotensive; can cause brachycardia. Interacts with del-

ta-, kappa- and mu-opiate receptors; NMDA-receptor antagonist. Toxic to some cancers (Bisset 1985a; Creasey 1994; Deecher et al. 1992; Layer et al. 1996; Okuyama et al. 1992).

Croweacin $C_{11}H_{12}O_3$

[4-methoxy-5-(2-propenyl)-1,3-benzodioxole; 1-allyl-2-methoxy-3,4-methylenedioxybenzene]

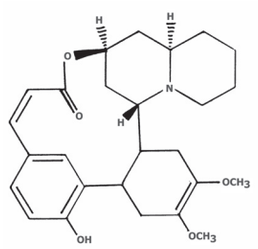


Oil; bp. 130–131/256–258°C.

Non-amine precursor to MMDA-3a [2-methoxy-3,4-methylenedioxy-*amphetamine*], which is active from 20-80mg, lasting 10-16hrs – increases visual awareness, causes CNS stimulation, mild psychedelic (Shulgin 1973; Shulgin & Shulgin 1991). MMDA-3a is a controlled substance.

Cryogenine $C_{26}H_{29}NO_5$

[vertine]

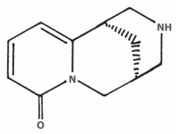


Crystals from methanol or chloroform; mp. 245–247/250–252°C.

Sedative, tranquilliser, hypotensive, hyperglycaemic, antiinflammatory, mydriatic. Antagonises binding to muscarinic *acetylcholine*-receptors, and acts as an antihistamine and non-specific *serotonin* antagonist (Kosersky & Malone 1971; Malone & Rother 1994; Nucifora & Malone 1971; Robichaud et al. 1965; Trottier & Malone 1969). As well as **Heimia** spp., found in Decodon verticillatus [see **Heimia**] and Lagerstroemia fauriei of the Lythraceae [see *Endnotes*]. This chemical is not the same as 1-carbamyl-2-phenylhydrazine, which is also known as cryogenine.

Cytisine $C_{11}H_{14}N_2O$

[baptitoxine; sophorine; ulexine]

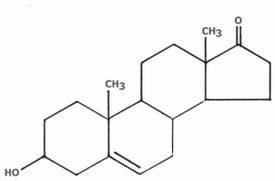


Orthorhombic prisms from acetone; mp. 152-155°C [sublimes]; bp. 218°C. Sol. in water, alcohol, benzene, chloroform, ethyl acetate, acetone, benzene; practically insol. in petroleum ether.

Nicotine-like activity peripherally; central effects are not *nicotine*-like, and have been little-studied, only manifesting in doses approaching the toxic; hypotensive, respiratory stimulant. Nicotinic *acetylcholine*-receptor agonist. Twice as toxic as *nicotine* orally, but active in smaller doses [¼ – ¾ that of *nicotine*] (Barlow & McLeod 1969; Kebadian & Neumeyer ed. 1994; Nucifora & Malone 1971; Reavill et al. 1990; Schmeller et al. 1994; Sloan et al. 1988). LD50 in mice [oral] – 101mg/kg; [i.p.] – 9.4-18mg/kg; [i.v.] – 1.73mg/kg (Buckingham et al. ed. 1994; Budavari et al. ed. 1989).

Dehydroepiandrosterone $C_{19}H_{28}O_2$

[DHEA; prasterone; dehydroisoandrosterone; transdehydroandros-terone; 3-hydroxyandrost-5-en-17-one; δ-5-androsten-3-β-ol-17-one; 17-hormoforin]

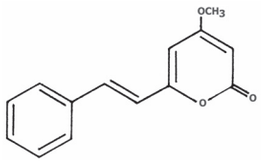


Dimorphous needles, mp. 140-141°C; or leaflets, mp. 152-153°C; sol. in benzene, alcohol, ether; sparingly sol. in chloroform, petroleum ether.

Anti-obesity, anti-aging, immune-stimulant and anti-tumour effects. Enhances cognitive functions, and improves neuron function and proliferation. Mediates limbic arousal. May be taken 50-2000mg a day; higher doses are less effective, as with many other cognitive-enhancers (Crenshaw & Goldberg 1996; Dean & Morgenthaler 1990); ligand for cannabinoid receptors, slightly more active than *anandamide* (Fride et al. 1995). Mammalian adrenal hormone, biosynthesised from cholesterol [via pregnenolone as an intermediate]; precursor to oestrogenic and androgenic steroidal hormones (Crenshaw & Goldberg 1996) – see *Neurochemistry*. Restricted or not approved in some countries.

5,6-Dehydrokawain $C_{14}H_{12}O_3$

[desmethoxyyangonin; 4-methoxy-6-(2-phenylethenyl)-2H-pyran-2-one; 4-methoxy-6-styryl-2H-pyran-2-one]



Mp. 138-140°C; sol. in alcohol, methanol/water, chloroform, oils.

Muscle relaxant, anaesthetic, potentiates barbiturate-induced sleep. CNS effects when given alone are minor [except when given i.v.]; however when combined with other 'kava-lactones' [see **Piper 2**] there is synergy (Keller & Klohs 1963; Klohs 1967; Meyer 1967). MAO-B inhibitor in human platelets; most potent in this regard of all kava-lactones tested (Uebelhack et al. 1998).

Also found in **Alpinia** [see **Kaempferia**, **Alpinia**], Aniba firmula, Didymocarpus pedicellata, and D. aurantiaca (Buckingham et al. ed. 1994).

Dermorphin

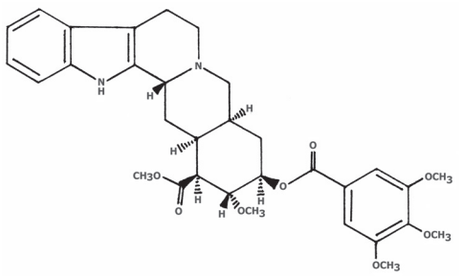
H-Tyr-D-Met-Phe-His-Leu-Met-Asp-NH_2

White powder; sol. in methanol.

Peptide with peripheral and central opiate-like activities; also has gastrointestinal effects, and effects on anterior pituitary functions. Agonist of mu-opiate receptors (Buckingham et al. ed. 1994; Lenga 1988; Melchiorri & Negri 1996).

Deserpidine $C_{32}H_{38}N_2O_8$

[reserpidine; recanescine; raunormine; harmonyl; canescine; 11-demethoxy-reserpine]

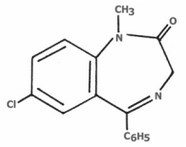


Three crystal forms from methanol – α [mp. 228-232°C], β [mp. 230-232°C] and γ [mp. 138/226-232°C with resolidification at 175°C].

Tranquilliser, antihypertensive, neuroleptic; may be toxic. Medicinal dose 0.25mg daily (Beckman 1961; Buckingham et al. ed. 1994; Harborne et al. ed. 1996).

Diazepam $C_{16}H_{13}ClN_2O$

[Valium™; diacepin; methyldiazepinone; 7-chloro-1,3-dihydro-1-methyl-5-phenyl-2H-1,4-benzodiazepin-2-one; 7-chloro-1-methyl-5-phenyl-3H-1,4-benzodiazepin-2(1H)-one]

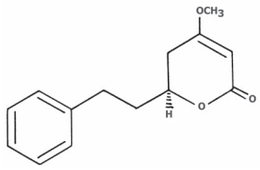


Plates from acetone and petroleum ether; mp. 125-126°C. Sol. in alcohol, acetone, chloroform, benzene; slightly sol. in water.

Depressant, anxiolytic, skeletal muscle relaxant (Budavari et al. ed. 1989); endogenous mammalian BZ-receptor agonist (Medina et al. 1989; Mousah et al. 1986; Müller 1987); potentiates effects of *adenosine* (Snyder & Sklar 1984). Active 5-10mg (Goodman & Gilman 1975). LD50 [oral] in rats – 710mg/kg (Budavari et al. ed. 1989). See *Neurochemistry*. This natural chemical was trademarked as the synthetic Valium before it was discovered in nature.

Dihydrokawain $C_{14}H_{16}O_3$

[marindinin]

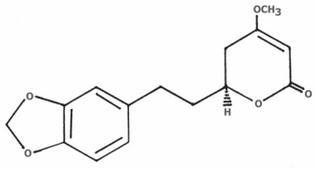


Crystals from ether; mp. 58-60°C. Sol. in alcohol, chloroform; moderately sol. in ether; practically insol. in water, petroleum ether.

Sedative, hypnotic, anaesthetic, anticonvulsant, potentiates barbiturate-induced sleep; causes ataxia in high doses (Keller & Klohs 1963; Klohs 1967; Meyer 1967). MAO-B inhibitor in human platelets, slightly less potent than *dihydromethysticin* in this regard, but weaker than *kawain* (Uebelhack et al. 1998). Also found in Aniba giganticola (Buckingham et al. ed. 1994).

7,8-Dihydromethysticin $C_{15}H_{16}O_5$

[dihydromethysticin; pseudomethysticin]

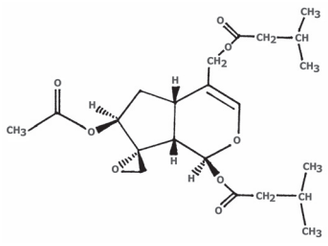


Prisms from methanol; mp. 117-118°C.

Causes "emotional and muscular relaxation, stabilisation of feelings and stimulation of the ability to think and act" (Lebot et al. 1999). Anticonvulsant, hypnotic, anaesthetic, potentiates barbiturate-induced sleep, protects against tissue damage from inadequate blood flow; can produce nausea and ataxia in high doses (Keller & Klohs 1967; Klohs 1967; Lebot et al. 1992; Meyer 1967; Singh & Blumenthal 1997). MAO-B inhibitor in human platelets, slightly less potent than *yangonin* in this regard (Uebelhack et al. 1998). Also found in Aniba gigantifolia (Buckingham et al. ed. 1994).

Dihydrovaltrate $C_{22}H_{32}O_8$

[didrovaltrate; didrovaltratum; dihydrovalepotriate]

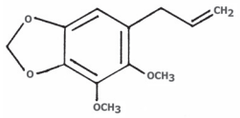


Mp. 63-64°C; sol. in chloroform, chloroform/methanol, alcohol/water, dichloromethane, oils or fats; insol. in water.

Sedative, tranquilliser, improves coordination (Buckingham et al. ed. 1994; Harborne & Baxter ed. 1993), spasmolytic, anticonvulsant (Hobbs 1993).

Dillapiole $C_{12}H_{14}O_4$

[1-ally-2,3-dimethoxy-4,5-methylenedioxybenzene; 4,5-dimethoxy-6-(2-propenyl)-1,3-benzodioxole]



Oil; mp. 29.5°C; bp. 285°C.

Insecticidal [also synergises with pyrethrins], molluscicidal (Buckingham et al. ed. 1994; Harborne & Baxter ed. 1993). Non-amine precursor to DMMDA-2 [2,3-dimethoxy-4,5-methylenedioxy-*amphetamine*]; DMMDA-2 is psychoactive at c.50mg, qualitatively said to be similar to MDA [see *safrole*] (Shulgin 1973; Shulgin & Shulgin 1991). DMMDA-2 is a controlled substance.

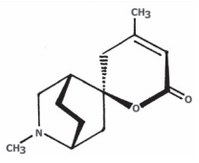
2-Dimethylaminoethanol $C_4H_{11}NO$

[DMAE; deanol; dimethyl-2-hydroxyethylamine; N-dimethylethanolamine]

Liquid; freezing point 40°C; bp. 135°C; miscible with water, alcohol, ether.

Often used as the p-acetamidobenzoate form [Deaner™]. CNS stimulant, antidepressant (Buckingham et al. ed. 1994; Budavari et al. ed. 1989), elevates mood, improves memory and learning, increases intelligence and physical energy, and can reputedly extend life-span. Some of these effects are controversial and may differ depending on dose, form of the drug taken, and length of administration. Treats symptoms of Huntington's chorea. Accelerates *choline* and *acetylcholine* synthesis, and increases *choline* and *acetylcholine* levels, though does not appear to act directly as a precursor as was once thought. One study (Zahniser et al. 1977) observed no noteworthy increases in these neurochemicals, though their treatment of test animals was not continued over an extended period [DMAE has a delayed effect – see below]. Precursor to phosphatidyl-*choline*, or may be broken down to phosphoryl-*choline*; enters the brain more efficiently than *choline*. Inhibits *choline* dehydrogenase. Has a delayed effect, and can be taken in gradually increasing doses up to 0.5-1g a day for at least three weeks, though some studies have observed some positive effects on concentration and sleep habits from as little as 10-20mg a day of the tartrate salt [which is poorly absorbed], and 'mild and pleasant' CNS stimulation from 10-20mg of the base [after 7-10 days of treatment]. After 3-4 weeks, a mild stimulation persists, but does not hinder sleep [though some studies found such higher doses to cause insomnia]; less sleep may be needed, and sleep may be sounder, with greater ease in morning functioning. After some 2 weeks of continuous use, however, the increase in *acetylcholine* reverses, and levels decline to normal (Dean & Morgenthaler 1990; Haubrich et al. 1981; Murphree et al. 1960; Osvaldo 1974; Pfeiffer et al. 1957). Can aid in induction of lucid-dreaming (Sergio 1988). Mammalian hormone, found in brain (Honegger & Honegger 1959). Flammable irritant (Lenga 1988). LD50 of the tartrate [oral] – c.3.1g/kg in mice, 2.6g/kg in rats; death due to respiratory depression and pulmonary oedema (Pfeiffer et al. 1957). Restricted or not approved in some countries. See *Neurochemistry*.

Dioscorine $C_{13}H_{19}NO_2$

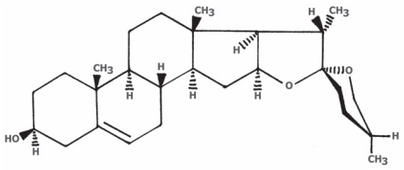


Greenish-yellow prisms from ether; mp. 43.5/54–55°C. Sol. in water, alcohol, acetone, chloroform; slightly sol. in ether, petroleum ether, benzene.

Analeptic, convulsant in large doses [up to 50mg/kg in mice]; mydriatic only at toxic doses. Similar effects to picrotoxin, but weaker. LD50 120mg/kg [i.p.] in mice. Dihydro-*dioscorine* appears to be inactive (Pinder 1953). Picrotoxin is a convulsant found in some plants used to poison fish; it is a *GABA*-antagonist (Goodman & Gilman 1975).

Diosgenin $C_{27}H_{42}O_3$

[nitogenin; dioscorea sapogenin; (3β,25R)-spirost-5-en-3-ol]

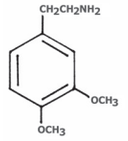


Crystals from acetone; mp. 204–207°C. Sol. in organic solvents and acetic acid.

Obtained by acid hydrolysis of many different saponins – eg. deltonin, deltoside or dioscin. Can be converted to pregnenolone, progesterone and other steroid hormones (Budavari et al. ed. 1989; Coppen 1980; Marker et al. 1940; Quigley 1978).

DMPEA $C_{10}H_{15}NO_2$

[3,4-dimethoxyphenethylamine; homoveratrylamine; 4-(β-aminoethyl)veratrole; 3,4-dimethoxybenzenethanamine]

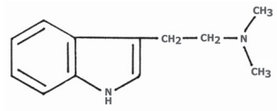


Crystals from benzene and petroleum ether; mp. 124°C; bp. 188°C.

Endogenous mammalian neurochemical, believed to be an abnormal metabolite or of dietary origin; so far not found to be psychoactive in humans [oral, 0.5-1g] (Kaplan & Sadock ed. 1989; Rosengarten & Friedhoff 1976; Shulgin 1973; Shulgin & Shulgin 1991), though 50-200mg/kg injected into rats resulted in 'hypokinesis'. N-Acetyl-*DMPEA*, a naturally-occurring metabolite of *DMPEA*, had similar activity at 1-5mg/kg, with quicker onset of effects. However in humans, it was not psychoactive in oral doses up to 1.2g (Johnson et al. 1970). It may be that these alkaloids do not easily enter the CNS (pers. obs.). *DMPEA* and its N-methylated homologues found in nature act as MAOIs, inhibiting deamination of *tyramine* and *tryptamine* by rat brain MAO – an action not observed with the β-hydroxylated derivatives (Keller & Ferguson 1976a, 1977). Despite this, *DMPEA* is oxidised by MAO (Goto et al. 1997). The related 4-MeO-*phenethylamine* and its N-methylated homologues inhibit the action of MAO on *tyramine*, but not *tryptamine* (Keller & Ferguson 1976b). This, and the MAOI activity of some isoquinolines [eg. see *salsolinol*] might contribute to the psychoactivity of normally orally-inactive *phenethylamine*s found in some 'peyotillos' and 'false peyotes' which are recorded as being psychoactive (pers. obs.). *DMPEA* has also shown neurotoxicity to dopaminergic neurons in vitro (Goto et al. 1997; Koshimura et al. 1997). Reduces hydroxyindole-O-methyltransferase [HIOMT] activity in bovine pineal (Hartley & Smith 1973). See *Neurochemistry*.

DMT $C_{12}H_{16}N_2$

[N,N-dimethyltryptamine; dimethyltryptamine; N,N-dimethyl-1H-indole-3-ethanamine; 3-[2-(dimethylamino)ethyl]indole]

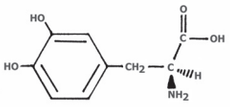


Crystals from ethanol; mp. 44.6–46.8°C; sol. in dilute acids, alcohols, acetone, chloroform, dichloromethane, ether, toluene, hexane, hot petroleum ether; slightly sol. in water; insol. in cold petroleum ether.

Psychedelic at 1mg/kg i.m., 0.2–0.4mg/kg i.v.; active by smoking at 25–100mg. Inactive orally at up to 350mg [without MAOI]. When smoked [preferably vapourised], as much as possible should be inhaled within 1 min. or so and held in for as long as practical – tolerance quickly sets in as the *DMT* is broken down by brain MAO, making extra inhalations capable of maintaining a peak but not increasing the strength of effect. With a fully effective dose, effects are felt after 20 seconds, and a rising tone vibration is sometimes both felt and heard [although some describe this merely as tinnitus, I do not agree that they are the same]. Blood pressure rises. From 30-60 seconds, the visual field is overwhelmed by intricate, rapidly metamorphosing visual effects; 1 minute to 5 minutes, perception of the body is not apparent, time dissolves and the mind exists in an extremely bizarre hyperspatial reality. After this time, visual phenomena subside, and the user is back to 'baseline' after c.30-60mins. Some people find it difficult to inhale a fully effective dose in the short time required before tolerance sets in. Lower doses are nowhere near as dramatic as high doses, and are best appreciated sitting or lying still with eyes closed. Oral doses combined with an MAOI take effect within 10–60mins, and last c.4hrs or less. A very powerful compound which should be approached with extreme respect. Agonist of postsynaptic 5-HT2a, and to a lesser extent 5-HT1a, 5-HT1d & 5-HT2c receptors [reducing *serotonin* levels]; also a ligand of the trace amine [TA] receptor, possibly leading to anxiolytic effects at small doses. Raises blood levels of β-*endorphin*, cortisol, *adrenocorticotropin* and prolactin. Peripheral vasopressor. Humans develop little tolerance with use several times a day, although at least 30 min. should be left between doses due to a short-term tolerance as mentioned above; produces little cross-tolerance with other indole psychedelics (Brimblecombe et al. 1964; Jacob & Presti 2005; McKenna et al. 1990; Shulgin 1976; Shulgin & Shulgin 1997; Smith, R.L. et al. 1998; Strassman 1992–1993, 1996; Strassman & Qualls 1994; Strassman et al. 1994, 1996; Szara 1961a; Turner & Merlis 1959; pers. obs.). Effects are enhanced by pre-administration of small amounts of LSD or *psilocybin* (Trout & Friends 1999). Endogenous mammalian neurochemical (Barker et al. 1981; Christian et al. 1977; Corbett et al. 1978; Gillin et al. 1976; Oon et al. 1977; Smythies et al. 1979; Tanimukai et al. 1970). MAOI in vitro, though not enough to be orally active, despite being the most potent MAOI of the tryptamines tested (Ho et al. 1970; McKenna et al. 1984b). Stimulates hydroxyindole-O-methyltransferase [HIOMT] activity in bovine pineal (Hartley & Smith 1973). Controlled substance. *DMT*-N-oxide, considered to be at least 10x less potent than *DMT* (McKenna et al. 1984b), is resistant to MAO metabolism in aerobic conditions (McKenna et al. 1984a), and is said to be active by smoking (Trout ed. 1997c). See *Neurochemistry*, *Influencing Endogenous Chemistry*.

L-DOPA $C_9H_{11}NO_4$

[3-hydroxy-tyrosine; 3,4-dihydroxy-phenylalanine; 2-amino-3-(3,4-dihydroxyphenyl) propanoic acid; levodopa]

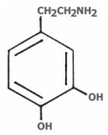


Colourless to white odourless and tasteless crystals; needles from water; mp. 276–278°C [dec.]/284–286°C. Sol. in dilute HCl and formic acid, water; practically insol. in ethanol, benzene, chloroform, ethyl acetate. In presence of moisture, readily oxidises and darkens.

Antidepressant, CNS stimulant; large doses induce locomotor stimulation, nausea, vomiting and 'involuntary chewing movements'; may exacerbate symptoms of schizophrenia, and induce psychotic symptoms in non-schizophrenics. Crosses blood-brain barrier easily, endogenous precursor to *dopamine* (Bell 1973; Boulton & Jiorio 1982; Malitz ed. 1972; Madras 1984; Moore 1978; Webster & Jordan ed. 1989). Sometimes taken with a decarboxylase inhibitor, to prevent it being transformed into *dopamine* before entering the brain. Sexual stimulant in low doses; inhibits this activity in high doses (Crenshaw & Goldberg 1996). Therapeutic dose 100-500mg (Goodman & Gilman 1975). LD50 in mice [oral] – 3650 mg/kg (Budavari et al. ed. 1989). Toxic to beetles and other insects (Harborne et al. ed. 1996). Restricted substance. See *Neurochemistry*.

Dopamine $C_8H_{11}NO_2$

[hydroxy-tyramine; 3,4-dihydroxy-phenethylamine; inotropin]



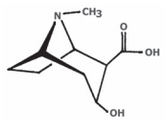
Stout prisms, highly sensitive to oxygen, discolours quickly [freebase] forming dopachrome [similar activity to *adrenochrome*]. HCl – rosettes of needles from water, mp. 240–241°C [dec.]; freely sol. in water; sol. in alcohol; practically insol. in ether, petroleum ether, chloroform, benzene and toluene.

Mammalian neurotransmitter, precursor to *norepinephrine*; does not easily cross blood-brain barrier; inactive orally without MAOI, though this combination presents a risk of hypertensive crisis. Adrenergic, sympathomimetic, vasopressor, cardiotonic, antihypotensive (Buckingham et al. ed. 1994; Budavari et al. ed. 1989; Cryer 1992; Goodman & Gilman 1975; Harborne et al. ed. 1996; Kaplan & Sadock ed. 1989; Madras 1984; Malitz ed. 1972; Moore 1978). Stimulates hydroxyindole-O-methyltransferase [HIOMT] activity in bovine pineal (Hartley & Smith 1973). CNS stimulant, euphoriant; causes feelings of pleasure, promotes orgasm (Crenshaw & Goldberg 1996; Malitz ed. 1972). Also found in the alga Monostroma fuscum. LD50 in rats [i.p.] – 163mg/kg (Buckingham et al.

ed. 1994). See *Neurochemistry*.

Ecgonine $C_9H_{15}NO_3$

[3-β-hydroxy-1-α-H,5-α-H-tropane-2-β-carboxylic acid]

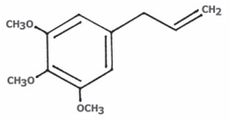


Triboluminescent monoclinic prisms from alcohol; mp. 198°C [dec. 205°C]. Sol. in water, alcohol, ethyl acetate; sparingly sol. in acetone, ether, benzene, chloroform, petroleum ether. Obtained by hydrolysis of *cocaine*.

Topical anaesthetic (Budavari et al. ed. 1989) weaker than *cocaine*, relieves hunger and fatigue, raises blood glucose levels. May have similar but much weaker cerebral effects to *cocaine* (Antonil 1978; Smith 1981). Toxic by inhalation, allergen (Buckingham et al. ed. 1994). Controlled substance; may be used to make *cocaine* (Clawson & Lee 1996; Smith 1981).

Elemicin $C_{12}H_{16}O_3$

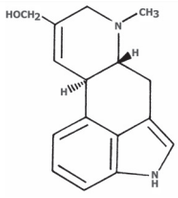
[1-allyl-3,4,5-trimethoxybenzene; 1,2,3-trimethoxy-5-(2-propenyl)benzene]



Oil; bp. 144–147/175°C; sol. in organic solvents.

Psychoactive in animals, causing excitation followed by sedation (Oswald et al. 1971b). Non-amine precursor to TMA [3,4,5-trimethoxy-*amphetamine*]; TMA is psychoactive at 100-250mg, lasting 6-8hrs – similar to *mescaline*, though less colourful visually (Shulgin 1973; Shulgin & Shulgin 1991; Shulgin et al. 1967), and similarly is a controlled substance.

Elymoclavine $C_{16}H_{18}N_2O$



Monoclinic prisms from methanol; mp. 248–252°C [dec.]. Fairly sol. in water with alkaline reaction; sol. in pyridine; very slightly sol. in organic solvents.

CNS excitant in animals; stimulates sympathetic nerves (Yui & Takeo 1958a, 1958b); hypotensive, brachycardiac, vasoconstrictor; *serotonin* antagonist (Takeo 1964); affects 5-HT2a receptors and α1-adrenoceptors in the rat (Pertz 1996), also stimulating *dopamine* receptors; stimulates pressor effects of *norepinephrine* and *nicotine*. In rats, 5mg/kg [i.p.] increased central *dopamine* levels in the hypothalamus and striatum, and increased its turnover in the striatum; increased levels and turnover of *norepinephrine* in the hypothalamus; and decreased *serotonin* levels and turnover in both these brain structures, whilst increasing *serotonin* levels in the cerebral cortex. LD50 over 24 hours was 228-535mg/kg in mice, and 81-258mg/kg in rats (Fuxe et al. 1978; Petkov & Konstantinova 1986; Petkov et al. 1984).

β-Endorphin H-Tyr-Gly-Gly-Phe-Met-Thr-Ser-Glu-Lys-Ser-Gln-Thr-Pro-Leu-Val-Thr-Leu-Phe-Lys-Asn-Ala-Ile-Ile-Lys-Asn-Ala-Tyr-Lys-Lys-Gly-Glu-OH

White powder.

Analgesic and behavioural activity like *morphine* and other opiates. Blocks inhibitory pathways in CNS. Mammalian neuropeptide (Kruk & Pycock 1983; Pomeranz 1977; Ree & de Wied 1983; Székely & Ronai 1982). See *Neurochemistry*.

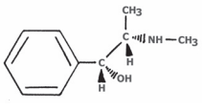
Enkephalins H-Tyr-Gly-Gly-Phe-X-OH [X=Met (*methionine*) or Leu (leucine)]

Met-*enkephalin* – needles from hot methanol; mp. 196–198°C. Leu-*enkephalin* – white crystalline solid; mp. 206°C [dec.].

Met-*enkephalin* and leu-*enkephalin* are opioid peptides with opiate-like effects; transient antinociceptive activity. Mammalian neuropeptides (Buckingham et al. ed. 1994; Herz 1980; Kruk & Pycock 1983; Ree & de Wied 1983; Székely & Ronai 1982; Székely et al. 1980). See *Neurochemistry*.

Ephedrine $C_{10}H_{15}NO$

[(1R,2S)-2-methylamino-1-phenyl-1-propanol]

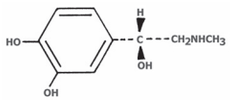


L-form – waxy solid, crystals or granules; gradually dec. on exposure to light; may contain up to 5.2% water; mp. 40°C; bp. 225°C; anhydrous material hygroscopic; mp. 34°C; sol. in water, alcohol, chloroform, ether, oils.

Indirect sympathomimetic agent, triggering release of catecholamines [*norepinephrine* most potently, as well as *dopamine*] and inhibiting their re-uptake; CNS stimulant similar to *amphetamine*; accelerates respiration and acts as a bronchodilator; decreases contractility of the bladder; vasoconstrictive. Agonist at α- and β-adrenergic receptors. Can cause tremors and insomnia (Bruneton 1995; Buckingham et al. ed. 1994; Goodman & Gilman 1975; Kalix 1991; Rothman et al. 2001). Potentiated by MAOIs (Iversen et al. ed. 1978), bringing the danger of hypertensive crisis. Japanese kamikaze pilots in WWII were reportedly given *ephedrine* injections ['philopon' – 'love of work']; after the war, there was an epidemic of injectable *ephedrine* abuse [by then called 'hirapon']. It has also been smoked with *caffeine* in the Philippines [see *caffeine*] (Karch 1996). Medicinal dose 15-50mg (Goodman & Gilman 1975); active as a CNS stimulant up to 200mg (pers. comms.; pers. obs.). Controlled substance [more than 20g]; otherwise restricted. Pseudoephedrine is less active as a CNS- and cardiac-stimulant, and the side-effects are more pronounced at psychoactive doses. Side effects of high doses include dry mouth, gagging, nausea and hypertension (Upfal 1995; pers. obs.).

Epinephrine $C_9H_{13}NO_3$

[adrenaline; 1-(3,4-dihydroxyphenyl)-2-methylaminoethanol]

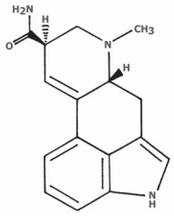


Off-white powder; mp. 211–216°C [dec. 215°C]; sparingly sol. in water; sol. in aqueous solutions of mineral acids, and of NaOH and KOH. Insol. in alcohol, ether, chloroform, acetone, oils.

Adrenergic, bronchodilator, mydriatic, antiglaucomic, vasoconstrictor, cardiac stimulant; may cause contact dermatitis. Used medicinally [i.m.] to relieve symptoms of anaphylaxis [severe allergic reaction]. Overdose and/or use outside of an appropriate medical context can be highly dangerous, resulting in cardiovascular disturbances and sometimes death. Active therapeutically around 0.5mg. High oral toxicity [antidote – guanine]. LD50 in mice [i.p.] – 4mg/kg. LD50 on the skin, in rats – 62mg/kg. Mammalian adrenal hormone and neurotransmitter. Does not cross the blood-brain barrier (Buckingham et al. ed. 1994; Budavari et al. ed. 1989; Cryer 1992; Goodman & Gilman 1975; Harborne et al. ed. 1996; Johnston et al. 2003; Marley & Stephenson 1972). Restricted substance. See *Neurochemistry*.

Ergine $C_{16}H_{17}N_3O$

[lysergic acid amide; lysergamide; LA-111; LSA; 9,10-didehydro-6-methylergonoline-8-β-carboxamide]

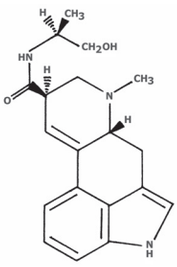


Prisms from methanol; mp. 242°C [dec.]; sol. in ethanol, methanol, chloroform; slightly sol. in water.

Psychoactive at 0.5–1mg; sedative, hypnagogic, causes sensitivity to sound-stimuli (Hofmann 1963). *Serotonin* antagonist (Cerletti & Doepfner 1958; Takeo 1964); slightly inhibits human plasma cholinesterase (Orgell 1963a). Stimulates hydroxyindole-O-methyltransferase [HIOMT] activity in bovine pineal (Hartley & Smith 1973). Controlled substance.

Ergonovine $C_{19}H_{23}N_3O_2$

[ergometrine; ergotrate; ergobasine; ergotocin; ergostetrine; d-lysergic acid-L-2-propanolamide; 9,10-didehydro-N-(2-hydroxy-1-methylethyl)-6-methylergoline-8-carboxamide]



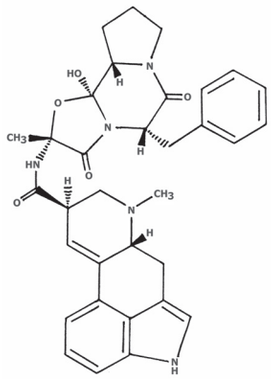
Tetrahedra from ethyl acetate; fine needles from benzene; mp. 162–163°C. Sol. in water, alcohol, ethyl acetate, acetone; slightly sol. in chloroform.

Mildly psychoactive and physiologically active from 0.65mg. Mild LSD-like psychedelic between 2–10mg, but with strong somatic side-effects [eg. leg cramps, physical sedation] increasing in intensity with increased dose; side effects were stated to overshadow the desirable effects, which were still relatively mild at the highest dose bioassayed and did not increase in intensity with the same magnitude as did these side effects; euphoria was minimal or absent [as *ergonovine* maleate] (Bigwood et al. 1979). Inhibits prolactin release; oxytocic; vasoconstrictor; uterotonic; used as a haemostatic to treat post-partum haemorrhage [0.2–0.4mg 2–4 times a day for several days]. Should not be used in the case of severe high blood pressure. *Serotonin* antagonist c.4x as potent as *ergine*; decreases *serotonin* levels and turnover; increases levels and turnover of *norepinephrine* and *dopamine*; binds to 5-HT2a receptors and α-1-adrenoceptors. Initially a D2 *dopamine*-receptor agonist, later becoming an antagonist. In rats, it caused "strong and long-lasting stimulation of locomotor activity" at 10mg/kg, due to activity at brain *dopamine* receptors. LD50 in rats 81–258mg/kg (Boissier 1978; Bruneton 1995; Cerletti & Doepfner 1958; Cools 1978; Pertz 1996; Petkov & Konstantinova 1986; Petkov et al. 1984; Rastogi & Mehrotra ed. 1990-1993; Upfal 1995).

Methylergonovine is c.3½ x as potent as a *serotonin* antagonist (Cerletti & Doepfner 1958), and is psychedelic at a dose of 2mg [similar in strength to a 10mg dose of *ergonovine*] (Ott & Neely 1980).

Ergotamine $C_{33}H_{35}N_5O_5$

[12'-hydroxy-2'-methyl-5'-(phenylmethyl)ergotaman-3',6',18-trione]

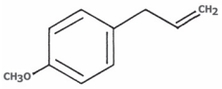


Elongated prisms from benzene; very hygroscopic, darkens on exposure to air, heat, light; mp. 213–214°C [dec.]; sol. in chloroform, pyridine, glacial acetic acid; moderately sol. in ethyl acetate; slightly sol. in benzene; almost insol. in water, petroleum ether.

Partial adrenergic agonist, later antagonist; *serotonin* antagonist; inhibits vasomotor centres; haemostatic; potent vasoconstrictor; oxytocic; hypertensive. Partly responsible for 'gangrenous ergotism' [see **Claviceps**]. Relieves migraine headaches, but does not prevent them. Sometimes available medicinally in combination with *caffeine*, which enhances the absorption of *ergotamine*. Can cause mental depression, confusion, drowsiness, weakness, headache and feeling of insects crawling under the skin. Active 2-4mg or more. High doses should be treated with caution and can result in impaired blood flow to legs, numbness in hands and feet, cold skin, gangrene, nausea, vomiting, diarrhoea, itching, strong thirst, seizures and unconsciousness. Should not be taken if suffering from severe infections, angina, severe high blood pressure, Raynaud's disease, impaired kidney or liver function, reduced blood flow to legs, arteriosclerosis or if pregnant or breast-feeding (Boissier 1978; Bruneton 1995; Buckingham et al. ed. 1994; Cerletti & Doepfner 1958; Goodman & Gilman 1975; Harborne & Baxter ed. 1993; Kruk & Pycock 1983; Upfal 1995). Restricted substance.

Estragole $C_{10}H_{12}O$

[methylchavicol; isoanethole; p-allylanisole; 1-methoxy-4-(2-propenyl)benzene; 1-allyl-4-methoxybenzene]

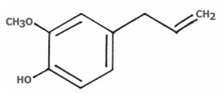


Liquid; bp. 95–96/108–114/216°C. Sol. in alcohol, chloroform; sparingly sol. in water.

Hypothermic, stimulates liver regeneration, binds to DNA (Harborne et al. 1996). Inhibits neuromuscular transmission, may have some anticholinergic activity (Albuquerque et al. 1995). A pheromone of the 'Southern' and 'Western corn rootworms' [Diabrotica undecimpunctata and D. virgifera] (Buckingham et al. ed. 1994). Carcinogenic in mice (Ames et al. 1987). LD50 in mice [oral] – 1250mg/kg (Budavari et al. ed. 1989). Non-amine precursor to 4-MA [see *anethole*] (Shulgin & Shulgin 1991; Shulgin et al. 1967).

Eugenol $C_{10}H_{12}O_2$

[5-allyl-guiacol; 2-methoxy-4-(2-propenyl)phenol; 1-allyl-4-hydroxy-3-methoxybenzene; 4-allyl-2-methoxyphenol]



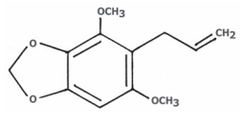
Colourless or pale yellow liquid with odour of cloves [see **Syzygium**] and spicy, pungent taste; bp. 248-255°C. Darkens and thickens on air exposure. Practically insol. in water; miscible with alcohol, chloroform, ether, oils; sol. in glacial acetic acid.

Psychoactive in animals, causing excitation followed by sedation (Oswald et al. 1971b); anticonvulsant, spasmolytic, hypothermic, antioxidant (Harborne & Baxter ed. 1993), insect attractant, analgesic [used in dentistry] (Buckingham et al. ed. 1994). LD50 in rats [oral] – 2680mg/kg (Budavari et al. ed. 1989). Non-amine precursor to 3,4-DMA [3,4-

dimethoxy-*amphetamine*], which is psychoactive from c.160mg and above, producing some *mescaline*-like symptoms (Shulgin 1973; Shulgin & Shulgin 1991; Shulgin et al. 1967); 3,4-DMA is a controlled substance.

Exalatacin $C_{12}H_{14}O_4$

[1-allyl-2,6-dimethoxy-3,4-methylenedioxybenzene; 2,6-dimethoxy-3,4-methylenedioxy-1-(2-propenyl)-benzene]

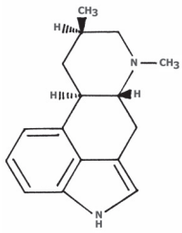


Oil; bp. 112–113°C; sol. in hexane, benzene, chloroform.

Non-amine precursor to 2,6-dimethoxy-3,4-methylenedioxy-*amphetamine* [DMMDA-3], of unknown human pharmacology (Torsten pers. comm. referring to comms. with A.T. Shulgin).

Festuclavine $C_{16}H_{14}N_2$

[dihydro-agroclavine]

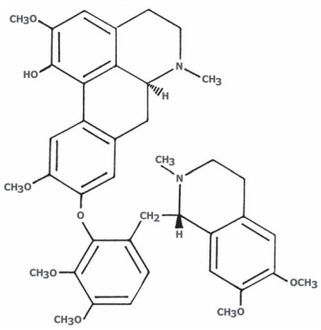


Long needles from methanol, mp. 238–242°C [dec. 239–240°C]; sol. in methanol, water/acetone, ether, chloroform.

Psychoactive in animals, causing CNS depression, drowsiness and slight mydriasis; reduced uptake of *norepinephrine* and *dopamine*, also reducing *dopamine* turnover (Fuxe et al. 1978; Yui & Takeo 1958a, 1958b). 5-HT2a-receptor and α1-adrenoceptor agonist in rats (Pertz 1996).

Foetidine $C_{40}H_{46}N_2O_8$

[fetidine]

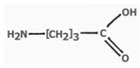


Crystals from ethyl acetate; mp. 132–135/125–126°C.

Nervous depressant, hypotensive, antiinflammatory (Buckingham et al. ed. 1994).

GABA $C_4H_9NO_2$

[gamma-aminobutyric acid; γ-aminobutyric acid; 4-aminobutanoic acid; piperidinic acid]

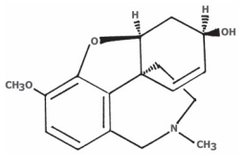


Leaflets from methanol and ether; needles from alcohol and water; mp. 202°C [dec. 203°C]. Freely sol. in water; insol. or poorly sol. in other solvents. On melting, it decomposes, forming water and pyrrolidone.

Antihypertensive, anticonvulsant; inhibitory effects in CNS. Can cause sedation, depression, muscle relaxation, analgesia. Mammalian neurotransmitter; does not cross the blood-brain barrier as well as its hydroxyl derivative, GABOB [gamma-amino-β-hydroxybutyric acid], which has similar activity to *GABA* and decreases brain *serotonin* [when given i.p.] (Buckingham et al. ed. 1994; Budavari et al. ed. 1989; De Maio & Pasquariello 1964; Kruk & Pycock 1983). *GABA* may antagonise *dopamine* activity (Kaplan & Sadock 1989). Reduces *vasopressin* levels; levels increase in male rats after orgasm (Crenshaw & Goldberg 1996). See *Neurochemistry*.

Galanthamine $C_{17}H_{21}NO_3$

[4a,5,9,10,11,12-hexahydro-3-methoxy-11-methyl-6H-benzofuro[3a,3,2-ef][2]benzazepin-6-ol; galantamine; galanthine; lycoremine]

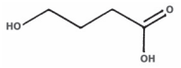


Crystals from benzene; mp. 126–129/133–134°C; sol. in hot water, alcohol, acetone, chloroform; less sol. in benzene, ether.

AChE inhibitor (Kametani et al. 1971; Vasilenko & Tonkopii 1975); powerful analgesic, inhibits traumatic shock, brachycardiac, restores non-depolarising neuromuscular blockage and restores synaptic transmission (Martin 1982). Doses of 5–10mg [3 times a day] have been safely given to Alzheimer's Disease patients, to relieve their symptoms; 15mg was noted to result in "central agitation and sleeplessness" (De Smet 1998). LD50 in mice [s.c.] – 11mg/kg. Found in a large number of plants from the Amaryllidaceae, such as Galanthus voronovii and **Narcissus** spp. (Buckingham et al. ed. 1994).

GHB $C_4H_8O_3$

[gamma-hydroxybutyric acid; gamma-hydroxybutyrate; γ-hydroxybutyrate; 4-hydroxybutanoic acid; 4-hydroxybutyrate; GBH; 'liquid ecstasy']

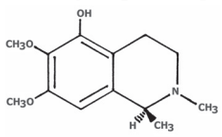


Often prepared as the sodium or potassium salts, which form white, hygroscopic crystals; sodium *GHB* – mp. 145–146°C; sol. in water.

Hypnotic, tranquilliser, weak analgesic; alcohol-like inebriant and euphoriant in low doses, though some people claim to experience mildly psychedelic effects. A low to moderate dose is considered to be 1-2g; coma, muscle spasms and vomiting may occur above 5g. Lasts 1-3 hours. Inhibits, then stimulates, *dopamine* release; large doses increase levels of *acetylcholine* and *serotonin*; increases cGMP levels; lowers glucose levels and utilisation. May be metabolite of *GABA*; found in relatively high levels in kidney, heart and skeletal muscle; unevenly distributed in brain. Highest concentrations in humans in foetal cerebellum and adult hypothalamus. LD50 [i.p., of sodium *GHB*] 2g/kg in male rats, 1.65g/kg in female rats. Toxicity greatly increased by alcohol (McCormick & Tunnicliff 1998; Tunnicliff 1992; pers. comms.). GBL [γ-hydroxybutyric acid lactone; γ-butyrolactone; 1,2-butanolide; 1,4-butanolide; dihydro-2(3H)-furanone] has similar effects to *GHB* in humans (Tunnicliff 1992; pers. comms.). See *Neurochemistry*.

Gigantine $C_{13}H_{19}NO_3$

[1,2,3,4-tetrahydro-5-hydroxy-6,7-dimethoxy-1,2-dimethylisoquinoline]

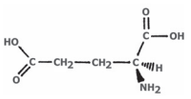


Crystals from ether; mp. 151-152°C.

Claimed to be "hallucinogenic" in cats and squirrel monkeys at 5mg/kg [i.p.]; lethal at 20mg/kg [i.p.] (Hodgkins et al. 1967).

Glutamic acid $C_5H_9NO_4$

[glutamate; 2-aminopentanedioic acid; 2-aminoglutaric acid]

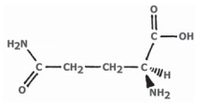


Rhombic crystals from dilute ethanol; mp. 211–213/224–225/247–249°C [dec.].

Excitatory amino acid and neurochemical (Kruk & Pycock 1983). From acid hydrolysis of proteins. Used as a seasoning additive in food [as Na, K and NH4 salts] (Buckingham et al. ed. 1994). See *Neurochemistry*.

Glutamine $C_5H_{10}N_2O_3$

[2,5-diamino-5-oxopentanoic acid]

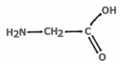


Needles from dilute ethanol; mp. 184–185°C; sol. in water; sparingly sol. in ethanol.

Psychotonic, alcohol antagonist. Widely distributed in plants, eg. in beetroot (Buckingham et al. ed. 1994). See *Neurochemistry*.

Glycine $C_2H_5NO_2$

[aminoacetic acid; glycocoll; glue sugar]

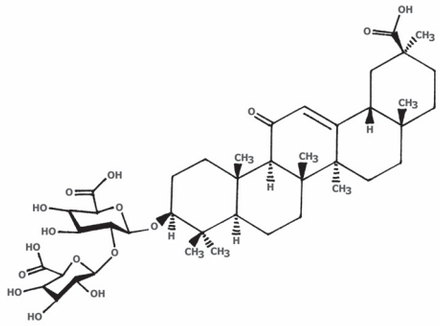


Crystals from dilute ethanol; mp. 262°C [dec.]; sol. in water; slightly sol. in alcohol.

Inhibitory amino acid (Kruk & Pycock 1983). Occurs widely in peptides and proteins (Buckingham et al. ed. 1994). See *Neurochemistry*.

Glycyrrhizin $C_{42}H_{62}O_{16}$

[glycyrrhitin; glycyrrhizic acid; glycyrrhizinic acid; glycyrrhetic acid 3-O-[β-D-glycopyranosyl(1→2)-α-D-glucopyranoside]

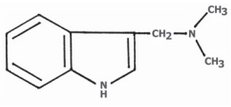


Crystals from glacial acetic acid, or hygroscopic powder; mp. c.220°C; freely sol. in hot water, alcohol; practically insol. in ether.

Adrenal tonic, antiinflammatory, expectorant, antihaemmorrhagic; has a protective action against saponin toxicity; MAOI. Can cause hypertension, sodium retention and heart enlargement if taken in excess (Buckingham et al. ed. 1994; Hall 1973; Hatano et al. 1991; Segal et al. 1977).

Gramine $C_{11}H_{14}N_2$

[3-(dimethylaminomethyl)indole; 3-(N,N-dimethylaminomethyl)indole; N,N-dimethyl-1H-indole; donaxine; doranine]

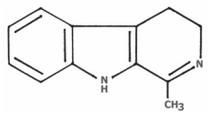


Shiny flat needles or plates from acetone; mp. 138–139°C; sol. in alcohol, ether, chloroform; slightly sol. in cold acetone; practically insol. in petroleum ether and water.

May have *ephedrine*-like actions; pharmacology unclear. In animals, first stimulates CNS [causing clonic convulsions and hyperpnoea], then depresses it – death may occur due to respiratory failure (Erspamer 1966). Behaviourally-active in rats, though 5-methoxy-*gramine* was much more effective (Gessner et al. 1961). Apparently psychotropic in sheep [10–30mg/kg i.v.], with effects noted after 10–15 seconds, and lasting 5–25min. [duration increasing with dose]; orally, *gramine* was quite toxic in large doses [400-600mg/kg], with effects beginning in 20min. to 1hr, death often resulting within a few hours (Bourke et al. 1988). Toxic to mammals, insects, plants, and bacteria (Corcuera 1993). In voles, it impaired kidney function and appeared to interfere with nutrient-utilisation; death often resulted with extended feeding [*gramine* was administered as a component of feed] (Goelz et al. 1980). In mammalian mitochondria [from rat liver and bovine heart], low doses slightly stimulated basal electron transport, and inhibited Ca2+-induced respiratory control; higher doses inhibited electron transport in the respiratory chain (Niemeyer & Roveri 1984). Inhibits human plasma cholinesterase (Orgell 1963a). MAOI activity has been demonstrated in vitro, but this is less potent than that of *DMT*, *5-methoxy-DMT* and *bufotenine*; 5-methoxy-*gramine* is also an MAOI, but less potent than *gramine* (Ho et al. 1970). Human toxicity was relatively unknown until recently, when *gramine* appeared as an obscure new health supplement. However, I have been unable to find reference to this outside of promotional literature. Suggested use is as a sedative and nerve tonic, to treat epilepsy, depression and *nicotine* withdrawal. Suggested doses are 100-200mg a day for children, 200-400mg for adults, with the only noted side effect from overdose being diarrhoea. Has been found to modulate blood pressure (Designed Nutritional Products undated).

Harmalan $C_{12}H_{12}N_2$

[3,4-dihydro-1-methyl-β-carboline; 4,9-dihydro-1-methyl-3H-pyrido[3,4-b]indole]

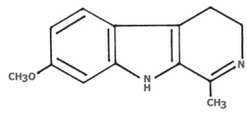


Cream needles from acetone; mp. 183–183°C [dec.].

MAOI in vitro (Buckholtz & Boggan 1977); endogenous neurochemical, sometimes formed as a result of alcohol consumption (Shulgin & Shulgin 1997). See *Neurochemistry*.

Harmaline $C_{13}H_{14}N_2O$

[dihydro-harmine; harmidine; 4,9-dihydro-7-methoxy-1-methyl-3H-pyrido[3,4-b]indole; 3,4-dihydro-7-methoxy-1-methyl-β-carboline]

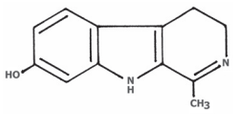


Orthorhombic bipyramidal prisms or tablets from methanol, rhombic octahedra from ethanol; mp. 227–231/250–251°C; solns. have blue fluorescence.

MAOI at 1.2–1.32mg/kg and above. Psychoactive at 150–500mg orally, lasting 5-8 hrs; causes sedation, intoxicated feeling, mild visual disturbances, often with lateral rippling effects and closed-eye eidetic imagery; mild psychedelic; causes nausea, dizziness, paraesthesia (Buckholtz & Boggan 1977; Kim et al. 1997; McKenna et al. 1984a; Naranjo 1967; Ott 1993, 1994; Shulgin 1977; Shulgin & Shulgin 1997; Udenfriend et al. 1958); antimalarial (Gröger 1959). Protects against oxidative neurotoxicity induced by *dopamine* or MPTP [1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine] (Lee, C.S. et al. 2000). Inhibits human plasma cholinesterase; inhibits Na+-dependent *choline* uptake, though more weakly than either *harmine* or *harmalol*; inhibits *GHB* synaptosomal transport; inhibits binding of leu-*enkephalin* to delta opiate-receptors; binds to *serotonin* receptors and I2 imidazoline receptors; weak NMDA-receptor antagonist; BZ-receptor antagonist; increasesc brain *serotonin*; inhibits adrenal *epinephrine* uptake, though less potent than *harmine*; has c.4x the tremorgenic potency of *ibogaine* in mice. Has a slower rate of uptake, and slower clearance rate, than *harmine*. Metabolised by O-demethylation to *harmalol* (Airaksinen et al. 1984; Carpéné et al. 1995; Du et al. 1997; Glennon 1981; Ho 1977; Layer et al. 1996; McCormick & Tunnicliff 1998; Mousah et al. 1986; Orgell 1963a; Saano & Airaksinen 1982; Smart 1981; Zetler et al. 1972). Lethal in rats at 120mg/kg [s.c.] (Mahmoudian et al. 2002). Controlled substance in some countries [Australia].

Harmalol $C_{12}H_{12}N_2O$

[4,9-dihydro-1-methyl-3H-pyrido[3,4-b]indol-7-ol; 3,4-dihydro-7-hydroxy-1-methyl-β-carboline]

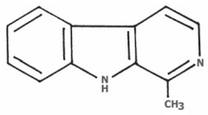


Fine orange or red needles from water; mp. 100–105°C; dec. 212°C [anhydrous]; aqueous solns. are yellow with green fluorescence; readily sol. in hot water, acetone, chloroform, alkali hydroxides, dilute acids, hot alcohol; slightly sol. in water, alcohol, ether; readily oxidised in air.

Weak MAOI in vitro in rat brain (Buckholtz & Boggan 1977); inhibits human plasma cholinesterase (Orgell 1963a); inhibits Na+-dependent *choline* uptake (Smart 1981); inhibits binding of leu-*enkephalin* to delta opiate-receptors (Airaksinen et al. 1984); binds to *serotonin* receptors (Glennon 1981); BZ-receptor antagonist (Mousah et al. 1986); protects against oxidative neurotoxicity induced by *dopamine* or MPTP [see *harmaline* above] (Lee, C.S. et al. 2000).

Harman $C_{12}H_{10}N_2$

[harmane; passiflorine; loturine; zygofabine; aribine; 1-methyl-9H-pyrido[3,4-b]indole; 1-methyl-β-carboline]

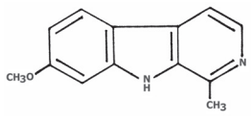


Bitter orthorhombic crystals from heptane and cyclohexane; mp. 237–238°C; exhibits bright blue fluorescence in UV light; practically insol. in water; sol. in dilute acids.

Plant growth inhibitor (Buckingham et al. ed. 1994). Is an MAOI experimentally, and binds to MAO (Buckholtz & Boggan 1977; Kim et al. 1997; May et al. 1994; McKenna et al. 1984a; Udenfriend et al. 1958), but in oral tests in humans of up to 250mg *harman* followed by 35mg *DMT*, no effects were noted (Ott 1994; Shulgin & Shulgin 1997), leading us to presume that *harman* is not an orally-active MAOI at this dose range. Inhibits plasma cholinesterase (Orgell 1963a); inhibits binding of leu-*enkephalin* to delta opiate-receptors (Airaksinen et al. 1984); BZ-receptor antagonist (Mousah et al. 1986; Saano & Airaksinen 1982); has c.½ the tremorgenic potency of *ibogaine* in mice (Zetler et al. 1972); also a free-radical scavenging antioxidant, a property shared by other β-carbolines (Tse et al. 1991). Inhibits AChE, and non-competitively inhibits muscarinic *acetylcholine* receptor binding, in rat brain (Skup et al. 1983). Catatonic motor-depressant in rats [10mg/kg]; higher doses [50mg/kg] were convulsive (Ho 1977). Mammalian neurochemical, possibly of dietary origin [eg. alcohol, cigarette smoke, soy sauce] or formed as a result of alcohol consumption (Callaway et al. 1995; Collins 1983; Shulgin & Shulgin 1997). LD50 in mice [i.p.] – 50mg/kg (Budavari et al. ed. 1989); lethal in rabbits at 200mg/kg [s.c.] (Mahmoudian et al. 2002). See *Neurochemistry*.

Harmine $C_{13}H_{12}N_2O$

[telepathine; yageine; banisterine; 7-methoxy-1-methyl-β-carboline; 7-methoxy-1-methyl-9H-pyrido[3,4-b]indole]

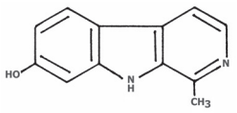


Slender orthorhombic prisms from methanol; mp. 257–259/261[dec., sublimes]/264–265°C; slightly sol. in water, alcohol, chloroform, ether.

MAOI at 140–190mg [or 1.5mg/kg] and above. Psychoactivity unclear in nature – widely differing responses to this chemical have been recorded at widely differing doses [40–900mg], some reporting no effects other than the physical, others reporting euphoria, mild CNS stimulation, sedation, and mild psychedelic effects; can cause hypotension, dizziness, nausea, ataxia, brachycardia (Buckholtz & Boggan 1977; Kim et al. 1997; McKenna et al. 1984a; Naranjo 1967; Ott 1994; Shulgin & Shulgin 1997; Udenfriend et al. 1958); can treat symptoms of Parkinson's Disease (Holmstedt 1982); antimalarial (Gröger 1959). Protects against oxidative neurotoxicity induced by *dopamine* or MPTP [see *harmaline* above] (Lee, C.S. et al. 2000). Inhibits Na+-dependent *choline* uptake, though more weakly than *harmalol* (Smart 1981); inhibits plasma cholinesterase (Orgell 1963a); binds to *serotonin* receptors (Glennon 1981); BZ-receptor antagonist (Mousah et al. 1986); has c.3x the tremorgenic potency of *ibogaine* in mice (Zetler et al. 1972). Slightly raises brain *dopamine* levels; inhibits adrenal *epinephrine* uptake. Metabolised by O-demethylation to *harmol* (Ho 1977). Apparently poorly absorbed through stomach; best taken sublingually or intranasally [in HCl form], or vapourised and inhaled [in base form] (pers. comms.; pers. obs.). LD50 in mice – 243mg/kg [s.c.] (Buckingham et al. ed. 1994), or 38mg/kg [i.v.] (Mahmoudian et al. 2002). Controlled substance in some countries [Australia].

Harmol $C_{12}H_{10}N_2O$

[7-hydroxy-harman; 7-hydroxy-1-methyl-β-carboline; 1-methyl-9H-pyrido[3,4-b]indol-7-ol]

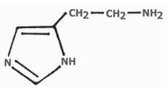


Mp. 304–307° C.

Weaker MAOI than *harmalol* in vitro, in mouse brain (Buckholtz & Boggan 1977), similarly potent to *harman* in rat liver (McKenna et al. 1984a); inhibits plasma cholinesterase (Orgell 1963a); inhibits binding of leu-*enkephalin* to delta opiate-receptors (Airaksinen et al. 1984); binds to *serotonin* receptors (Glennon 1981). CNS-depressant in rats; caused paralysis in higher doses (Ho 1977).

Histamine $C_5H_9N_3$

[ergamine; 1H-imidazole-4-ethanamine; 4-(2-aminoethyl)-1H-imidazole]

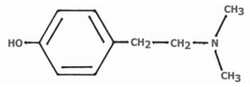


Deliquescent needles from chloroform; mp. 83–84/86°C; bp. 167/209–210°C; freely sol. in water, alcohol, hot chloroform; sparingly sol. in ether.

Potent vasodilator; gastric secretion stimulant; regulates body temperature; activates suppressor cells, reduces antibody secretion. Causes localised oedema response in mammalian tissues; can cause hypotension, tachycardia, increased heart rate and contractility. Involved in motion sickness; may aid in memory retention. Stimulates cAMP in brain, increases *norepinephrine* release, indirectly excitatory in neurons [potentiates excitatory signals]; may increase *vasopressin* secretion. Increases plasma levels of β-*endorphin*, *adrenocorticotropin*, corticosterone and β-lipotropin. Eating causes its release from gastric mucosa. Mammalian neurotransmitter. Does not cross the blood-brain barrier; is also mostly prevented from entering blood by an intestinal barrier. LD50 in mice [i.p.] – 2020mg/kg (Buckingham et al. ed. 1994; Budavari et al. ed. 1989; Levi et al. 1991; Maslinski & Fogel 1991; Schwartz 1991; Tasaka 1991; Watanabe et al. 1991; Yamatodani et al. 1991). *Histamine* antagonists can cause sedation, antidepression, analgesia and some degree of delirious intoxication at higher doses (pers. obs.; Schwartz 1991; Yamatodani et al. 1991). See *Neurochemistry*.

Hordenine $C_{10}H_{15}NO$

[peyocactine; cactine; anhaline; eremursine; N,N-dimethyltyramine; 4-hydroxy-N,N-dimethylphenethylamine; 4(2-dimethylaminoethyl)phenol]



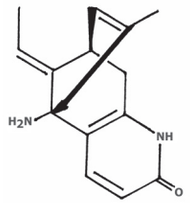
Orthorhombic prisms from alcohol or benzene/petroleum ether, needles from water; mp. 117–118°C; bp. 173–174°C; sublimes 140–150°C; very sol. in alcohol, chloroform, ether, water; sparingly sol. in benzene, toluene, xylene.

Hypertensive in large doses with *ephedrine*-like excitant action in animals; the methiodide has been reported to show *nicotine*-like activity in animals; diuretic, disinfectant, treats dysentery; grasshopper feeding deterrent (Buckingham et al. ed. 1994; Henry 1939). LD50 in mice – 113.5mg/kg (Budavari et al. ed. 1989). In voles, it appeared to be relatively non-toxic (Goelz et al. 1980) and antibiotic (McCleary et al. 1960). Appears to be mildly psychotropic in sheep [20–160mg/kg i.v.], with effects beginning in 10–15 seconds, and lasting 5–90min. [duration increasing with dose]; convulsions were noted in some sheep at the highest dose. Orally, doses of 200–400mg/kg were inactive; 800mg/kg was active with effects [milder, but similar in character to the 160mg/kg i.v. dose] begin-

ning in 30min. and lasting up to 1hr (Bourke et al. 1988).

Huperzine A $C_{15}H_{18}N_2O$

[selagine; 5-amino-11-ethylidene-5,8,9,10-tetrahydro-7-methyl-5,9-methanocycloocta[b]pyridin-2(1H)-one]

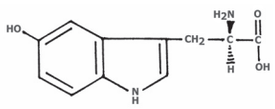


Crystals from acetone; amorphous base with odour of *coniine*; forms deliquescent salts; mp. 214–215/224–226/230°C; sol. in chloroform, methanol, water/tartaric acid.

Very strong AChE-inhibitor, and NMDA-receptor antagonist; markedly increases efficiency of learning and memory; the B-form has similar effects. Used to treat dementia from Alzheimer's Disease, myasthenia gravis (Liu et al. 1986; Tang et al. 1994; Zhang & Hu 2001; Zhou et al. 1993). See *Influencing Endogenous Chemistry*.

5-Hydroxytryptophan $C_{11}H_{12}N_2O_3$

[(S)- or (L)-form (natural form) – oxitriptan; levothym; serotonyl; triptene; 5-HTP]

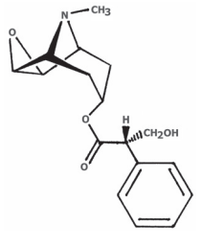


Pale pink needles or crystals; mp. 273°C [dec.]; dl-form sol. in water or 50% boiling alcohol; aqueous solns. stable at low pH.

Biogenic precursor to *serotonin*, increases *serotonin* levels (Bell 1973; Van Praag 1981; Webster 1989). Antidepressant and slight sedative at 50-500mg, sometimes euphoriant; more effective as an antidepressant in people with low endogenous *serotonin* levels. Takes effect within 1-3 weeks of daily use (Van Praag 1981), though one study noted beneficial effects within 3-5 days (Zmilacher et al. 1988). Further studies are needed to determine the spectrum of efficacy for *5-HTP* in treating different types of depression (Shaw et al. 2002). Side effects may include nausea, vomiting and diarrhoea, which Van Praag (1981) found could be largely eliminated by coating tablets with a pH buffer, so that the drug is not absorbed until it reaches the intestine (Van Praag 1981). Large doses cause mydriasis and excitation similar to that produced by LSD, in animals. Active at much lower doses with MAOI (Iversen et al. ed. 1978; Mantegazzini 1966) or a peripheral decarboxylase inhibitor [to prevent decarboxylation to *serotonin* before entering the brain] (Van Praag 1981). One study found no difference in efficacy of antidepressant action between *5-HTP* alone or with a decarboxylase inhibitor, but noted that patients using the latter combination were more likely to develop acute anxiety as a side effect (Zmilacher et al. 1988). Can suppress migraine headaches (Nicolodi & Sicuteri 1999). Weak MAOI in rat liver (McKenna et al. 1984b). Lowest LD50 in rodents 243mg/kg (Lewis 2000). Metabolite of Chromobacterium violaceum (Buckingham et al. ed. 1994). Some commercially-available *5-hydroxytryptophan* has caused symptoms similar to those of eosinophilia-myalgia syndrome, the same complication which resulted in the banning of *tryptophan*; such samples have been found to contain contaminants which have not been fully identified (Klarskov et al. 1999). Only available on prescription in some countries [such as Australia]. See *Neurochemistry*.

Hyoscine $C_{17}H_{21}NO_4$

[l-hyoscine; scopolamine; α-(hydroxymethyl)benzeneacetic acid 9-methyl-3-oxa-9-azabicyclo[3.3.1.02,4]non-7-yl-ester]



Viscous liquid, forms a crystalline monohydrate; mp. 59°C; freely sol. in hot water, alcohol, ether, chloroform, acetone; sparingly sol. in benzene, petroleum ether; easily hydrolysed by acids or alkalis; dec. on standing.

Anticholinergic hallucinogen [blocks muscarinic *acetylcholine*-receptors] similar to *atropine*. Mydriatic, antispasmodic, bronchodilator. Low doses cause drowsiness, euphoria, fatigue, amnesia, loss of concentration, and dry mouth; higher doses cause excitation, restlessness, motor incoordination, tachycardia, hallucinations and delirium, ending with brachycardia, inability to focus and mydriasis. The hallucinogenic effects are exacerbated by pain. Used in pre-operative medication. Psychoactive orally above 2mg; used therapeutically, 0.6mg as the hydrobromide. Can be absorbed through the skin. More toxic than *atropine*, though doses of 500mg have been survived. Reactions to this chemical in humans can be highly variable (Beckman 1961; Goodman & Gilman 1975; Moran 1993; Safer & Allen 1971; Terry et al. 1993). Has been shown to weakly inhibit MAO and *5-hydroxytryptophan* decarboxylase (Rastogi & Mehrotra ed. 1990-1993).

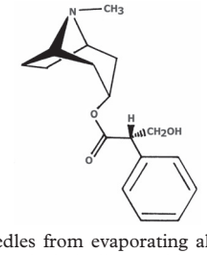
It has been used to control psychosis [often in combination with an opiate], and occasional intoxications have resulted when patients have overdosed on their medication. Accounts from some of these events are quite amusing to read. I could not resist giving some examples:

"A married man, aged 22 years, was brought into hospital after being found clad only in a pair of shorts, sitting in the middle of the road at about 8pm. He told the police he was flying an invisible aircraft by remote control [...] he said that he could hear bells ringing and he smoked imaginary cigarettes, tapping them out into plain glass ashtrays, described by the patient as decorated with nymphs and goddesses."

"A housewife, aged 25 years [...] had woken at midnight saying that the sitting-room was full of people [...] she plucked imaginary ice cream cones from the air and carried on a conversation with a non-existant girl friend, who she alleged was sitting on the kitchen stove" (Whitlock & Fama 1966).

Hyoscyamine $C_{17}H_{23}NO_3$

[(S)-tropine tropate; (S)-α-(hydroxymethyl)benzeneacetic acid 8-methyl-8-azabicyclo[3.2.1]oct-3-yl ester]

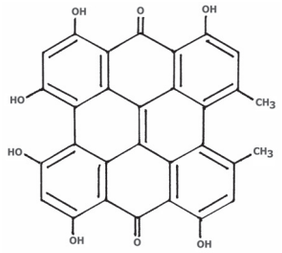


Silky tetragonal needles from evaporating alcohol; mp. 108–111°C; freely sol. in chloroform, alcohol, dilute acids; sol. in water, ether, benzene. Keep well closed and protected from light and heat; easily racemised to *atropine* – sometimes occurs naturally as a partial racemate.

Anticholinergic hallucinogen, acting at muscarinic receptors. Twice as potent as *atropine*; l-*hyoscyamine* is 8–50x as potent as d-*hyoscyamine* (Goodman & Gilman 1975). Similar activity to *atropine*, though more potent peripherally (Henry 1939). Also mydriatic, antispasmodic, antisecretory and antiemetic. Used in pre-operative medication, and to treat symptoms of Parkinson's Disease (Harborne & Baxter ed. 1993).

Hypericin $C_{30}H_{16}O_8$

[hypericum red; mycoporphyrin; 1,3,4,6,8,13-hexahydroxy-10,11-dimethylphenanthro[1,10,9,8-opqra]perylene-7,14-dione]

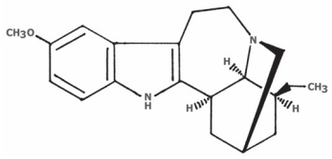


Solvated blue-black needles from pyridine and methanolic HCl; dec. 320°C; yields cherry red soln. with red fluorescence in organic bases; freely sol. in pyridine and other organic bases; almost insol. in most other organic solvents; sol. in alkaline aqueous soln.; below pH 11.5 solns. are red; above they are green with red fluorescence.

Tonic, tranquillising and antidepressant in very small quantities (Buckingham et al. ed. 1994; Budavari et al. ed. 1989); has shown weak MAOI activity in vitro, though inhibition for type A was stronger (Suzuki et al. 1984); binds to muscarinic *acetylcholine*-receptors and sigma-receptors (Raffa 1998). Inhibits HIV-replication in vivo (Eich et al. 1990).

Ibogaine $C_{20}H_{26}N_2O$

[12-methoxy-ibogamine]

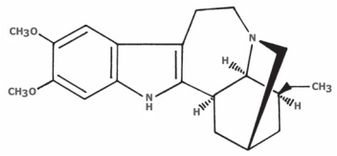


Prismatic needles from absolute ethanol; mp. 152–153°C [sublimes 150°C]; sol. in ethanol, ether, chloroform, acetone, benzene; practically insol. in water.

CNS stimulant, and psychedelic at higher doses, anticonvulsant, hypotensive, potentiates catecholamine-induced hypertension, tremorgenic [at 12.1 mg/kg (s.c.) in mice] (Bert et al. 1988; Buckingham et al. ed. 1994; Pope 1969; Popik et al. 1995; Zetler et al. 1972), can cause brachycardia; lowers body temperature. Inhibits AChE; inhibits MAO activity on *serotonin*, and catalyses it on catecholamines; reduces *glutamic acid*-induced neurotoxicity; NMDA-receptor antagonist; potentiates *morphine* analgesia and inhibits *morphine* withdrawal syndrome symptoms; partial agonist of kappa-opiate receptors; binds to sigma-receptors; blocks *dopamine* receptors for a long period, and alters their response to *morphine*, *cocaine*, *amphetamine*, alcohol and other addictive agents; increases extracellular levels of *serotonin* in the striatum and nucleus accumbens. Can be used to abolish addiction to heroin and other substances. Active 100mg-1g or more; psychedelic activity above 300mg, though unlike 'typical' serotonergic psychedelics. From 15–20mins after ingestion, an auditory oscillation and/or buzzing is heard/felt, and objects appear to vibrate intensely; skin is numb. From 1 hour after ingestion the unusual visionary phase begins – seems to be a kind of inward primal, regressive psychological state that takes the user to the root of their problems; 5–10hrs later, visions subside, and a stimulatory phase sets in, lasting 5–8hrs, with flashing lights experienced all around. There is usually insomnia after the experience, lasting up to 20 hours, from residual stimulation (Cappendijk et al. 1994; Deecher et al. 1992; De Rienzo et al. 1997; Layer et al. 1996; Popik & Skolnick 1999; Popik et al. 1995; Wei et al. 1998). LD50 in rats – 145mg/kg [i.p.]. Controlled substance in some countries. Animal studies demonstrated some neurotoxicity in large doses; however, this was not observed in therapeutic doses. After ingestion, *ibogaine* forms an active metabolite, nor-*ibogaine*, which is thought to mediate the long-lasting after-effects of *ibogaine*, especially in the case of drug-withdrawal therapy. Nor-*ibogaine*, like *ibogaine*, binds to kappa-opiate receptors [with a greater affinity than *ibogaine*] and NMDA receptors, decreases extracelleular *dopamine* levels in the striatum and nucleus acumbens, increases extracellular *serotonin* levels in the same brain areas, has an affinity [probably inhibitory] for *serotonin*-transport systems [much greater affinity than *ibogaine*], antagonises the motor-stimulant effects of *morphine*, and decreases alcohol, *cocaine*, and *morphine* self-administration in rats. Unlike *ibogaine*, it does not appear to be tremorgenic (Glick et al. 1996; Wei et al. 1998).

Ibogaline $C_{21}H_{28}N_2O_2$

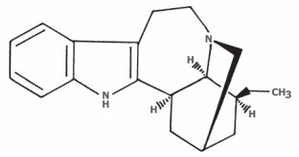
[10,11-dimethoxy-ibogamine; descarbomethoxy-conopharyngine]



Crystals from methanolic aqueous soln.; mp. 141–143°C.

CNS stimulant similar to *ibogaine*. Hypotensive and brachycardiac in anaesthetised cats. Tremorgenic at 2.6mg/kg [s.c.] in mice; LD50 in mice [i.v.] – 46mg/kg (Bert et al. 1988; Buckingham et al. ed. 1994; Van Beek et al. 1984; Zetler et al. 1972). Partial agonist of kappa-opiate receptors (Deecher et al. 1992).

Ibogamine $C_{19}H_{24}N_2$

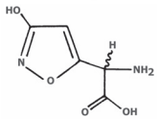


Crystals; mp. 162–164°C; sol. in ethanol, methanol, benzene, cyclohexane.

CNS-stimulant similar to *ibogaine*, hypotensive, tremorgenic, can cause brachycardia, shows some cytotoxic activity, weak antibacterial (Bisset 1985a; Buckingham et al. ed. 1994; Zetler et al. 1972). Partial agonist of kappa-opiate receptors (Deecher et al. 1992); NMDA-receptor antagonist (Layer et al. 1996).

Ibotenic acid $C_5H_6N_2O_4$

[pre-muscimol; α-amino-2,3-dihydro-3-oxo-5-isoxazoleacetic acid]

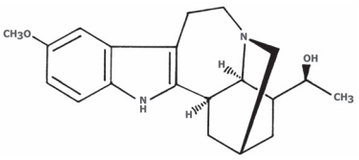


Crystals from water or methanol; mp. 151–152[anhydrous; dec.]/144-146°C [monohydrate].

Potent *GABA*-agonist, and *glutamic acid*-like excitant (Johnston et al. 1968). 'Entheogenic' at 1mg/kg (Ott 1993). A 20mg oral dose caused slight facial flushing, followed by lassitude and sleep, and later, persistent migraine, headache behind the eyes, and one-sided visual disturbance trailing off over 2 weeks[!]. LD50 in mice – 15mg/kg [i.v.], 25mg/kg [i.p.], 50mg/kg [p.o.] (Benedict 1972; Waser 1967), 38mg/kg [oral]; in rats – 42mg/kg [i.v.], 129mg/kg [oral] (Budavari et al. ed. 1989). Insecticidal (Buckingham et al. ed. 1994). Believed to be +- inactive until metabolised to *muscimol* (Ott 1993). Ibotenate, the racemate of *ibotenic acid*, caused initial excitation followed by prolonged depression of sensitivity of neurons to excitant amino acids and *acetylcholine* (Curtis et al. 1979; Puil 1981).

Iboxygaine $C_{20}H_{26}N_2O_2$

[descarbomethoxy-voacangarine; kimvuline]

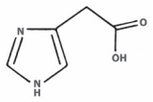


Mp. 235–236°C.

CNS stimulant similar to *ibogaine*; causes psychomotor effects; tremorgenic [at 26.2mg/kg (s.c.) in mice] (Bisset 1985a; Zetler et al. 1972); caused brachycardia and hypotension in anaesthetised cats, weak antibacterial. LD50 in mice [i.v.] – 42mg/kg (Buckingham et al. ed. 1994; Van Beek et al. 1984).

Imidazole-4-acetic acid $C_5H_6N_2O_2$

[imidazoleacetic acid; IMA]

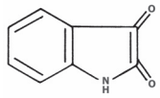


Crystals; mp. 222°C [dec.].

Endogenous metabolite in nervous system; has been found in brain, cerebrospinal fluid, and plasma. Hypnotic, can cause seizures. Potently displaces *GABA* from *GABA*a-receptors; antagonist at *GABA*c-receptor, possibly a weak partial agonist; binds to I1-imidazoline receptor. Enhances binding of benzodiazepines to *GABA*a-receptors. Blocks phencyclidine [PCP]-induced behavioural stimulation (Maslinski & Fogel 1991; Tunnicliff 1998). See *Neurochemistry*.

Isatin $C_8H_5NO_2$

[1H-indole-2,3-dione]



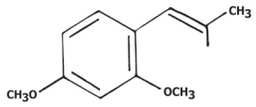
Orange crystals; mp. 203–205°C [dec., sublimes]. Sparingly sol. in water.

Component of endogenous *tribulin*, so far found in human urine, and in rat heart and brain. Used as an intermediate for indigoid dyes; also used as 0.2% methanol soln. for photometric detection of thiophene, proline and hydroxyproline.

MAO-B inhibitor, inhibits MAO-A much more weakly; increases *acetylcholine* and *dopamine* levels in rat brain, increases brain *serotonin*, but not in pineal; inhibits binding to BZ-receptors. Some studies have not duplicated MAOI activity. Early tests showed it to increase vigilance, reduce slow-wave sleep, and cause greater incidence of spontaneous rhythmic EEG activity (Glover 1998; Glover et al. 1988; Hucklebridge et al. 1998b; McIntyre & Norman 1990; Medvedev 1999; Minami et al. 1999; Yuwiler 1990). See *Neurochemistry*.

Isoosmorrhizole $C_{11}H_{14}O_2$

[isoosmorhizole; nothosmyrnol; 2,4-dimethoxy-1-(-1-propenyl)benzene]

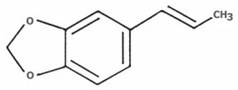


Bp. 75-77°C; sol. in hexane/benzene.

Non-amine precursor to 2,4-DMA [see entry for *osmorrhizole*] (Shulgin & Shulgin 1991).

Isosafrole $C_{10}H_{10}O_2$

[5-(1-propenyl)-1,3-benzodioxole; 1,2-(methylenedioxy)-4-(1-propenyl)benzene]

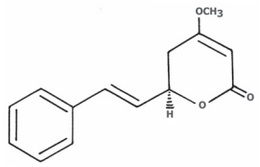


Liquid, odour of anise [see **Illicium**, **Pimpinella**]. Trans-form – mp. 8.2°C; bp. 85–86/135.6/179.5/253°C; miscible with alcohol, ether, benzene. Cis-form – mp. -21.5°C; bp. 77–79°C.

Psychoactive in animals, causing excitation followed by sedation (Oswald et al. 1971b). Non-amine precursor to MDA [see *safrole*] (Shulgin & Shulgin 1991).

Kawain $C_{14}H_{14}O_3$

[5,6-dihydro-4-MeO-6-(2-phenylethenyl)-2H-pyran-2-one; 5-OH-3-MeO-7-phenyl-2,6-heptadienoic acid δ-lactone; 4-MeO-6-(β-phenylvinyl)-5,6-dihydro-α-pyrone]



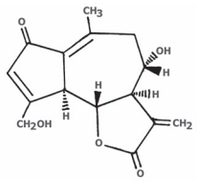
(+)-Form – rods from methanol and ether; mp. 105–106/110°C; bp. 195-197°C; practically insol. in water; sol. in acetone, ether, methanol; slightly sol. in hexane.

(+/-)-Form – needles from methanol; mp. 146–147°C.

Muscle relaxant, anticonvulsant, anaesthetic, sedative, causes ataxia in high doses, potentiates barbiturate-induced sleep (Buckley et al. 1967; Keller & Klohs 1963; Klohs 1967; Meyer 1967). Inhibits *norepinephrine*-uptake in rat brain (Seitz et al. 1997); MAO-B inhibitor in human platelets – in this regard, the least potent of the 'kava-lactones' tested [see **Piper 2**] (Uebelhack et al. 1998).

Lactucin $C_{15}H_{16}O_5$

[(5-α,6-α,8-α)-8,15-dihydroxy-2-oxo-1(10),3,11(13)-guaiatrien-12,6-olide]

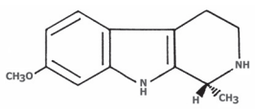


Crystals from methanol; mp. 224–233°C [sinters at 218°C]; sol. in water, ethanol, methanol, ethyl acetate, dioxane anisol.

A sesquiterpene lactone with CNS-sedative, cytotoxic, antitumour and bitter tonic properties; antagonises action of coffee [see **Coffea**] and tea [see **Camellia**]. LD50 in mice [oral] – 0.8–1.0mg/g (Forst 1941; Harborne & Baxter ed. 1993).

Leptaflorine $C_{13}H_{16}N_2O$

[tetrahydroharmine; THH; 2,3,4,9-tetrahydro-7-methoxy-1-methyl-1H-pyrido[3,4-b]indole; 1,2,3,4-tetrahydro-7-methoxy-1-methyl-β-carboline]

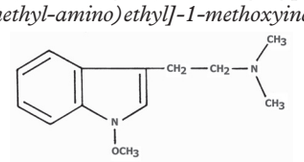


Mp. 198.4–199.8°C; sol. in chloroform, methanol. (+-)-Leptaflorine is synthetic; needles from methanol; mp. 199.4–199.8°C.

Roughly 1/3 the potency of *harmaline* as regards psychoactivity [active around 300mg orally], with similar effects; however, this is only from one human bioassay (Naranjo 1967; Shulgin & Shulgin 1997); also less potent than *harmaline* as an MAOI in vitro (Buckholtz & Boggan 1977; McKenna et al. 1984a; Udenfriend et al. 1958); weakly inhibits *serotonin*-uptake (Callaway et al. 1999). Vasodilator, tranquilliser (Trout ed. 1998, citing Raymond-Hamet 1941, C.R. Soc. Biol. 135:69-73 and Usdin & Efron 1979, Psychotropic Drugs and Related Compounds, respectively). Claimed to also be psychoactive when administered with MAO-inhibition from another agent, or when smoked (Trout ed. 1998, citing Callaway 1995, Eleusis 1:4–10); further details are lacking, and its oral MAOI capabilities remain to be demonstrated in humans (Trout ed. 1998).

Lespedamine $C_{13}H_{18}N_2O$

[1-MeO-DMT; 1-methoxy-N,N-dimethyltryptamine; 3-[2-(dimethyl-amino)ethyl]-1-methoxyindole]

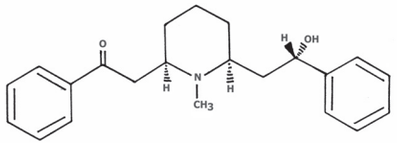


Colourless viscid oil; bp. 100–106/113–114°C; sol. in methanol.

Thought to probably be psychoactive by smoking; untested (Shulgin & Shulgin 1997).

Lobeline $C_{22}H_{27}NO_2$

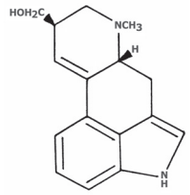
[8,10-diphenyllobelionol; 2-[6,2-hydroxy-2-phenylethyl)-1-methyl-2-piperidinyl-1-phenylethanone]



L-form [α-lobeline; inflatine] – needles from alcohol, ether, benzene; mp. 130–131°C; very slightly sol. in water or petroleum ether; sol. in hot alcohol, chloroform, benzene, ether; oxidation gives the symmetrical lobelanine [meso-*lobeline*].

Has action similar to *nicotine* in peripheral tissues, but *nicotine*-like central effects are yet to be demonstrated, possibly due to the fact that unlike *nicotine*, it does not cause *dopamine* release. Cognitive enhancer, emetic, hypotensive, respiratory stimulant, though depresses respiration in high doses; binds to nicotinic *acetylcholine* receptors; NMDA-receptor antagonist; inhibits plasma cholinesterase (Aizenman et al. 1991; Decker et al. 1993; Orgell 1963a; Reavill et al. 1990; Sloan et al. 1988); hyperalgesic when injected into rat brainstem, more potent than *morphine* (Hamann & Martin 1994). Also in seeds of Campanula medium (Buckingham et al. ed. 1994).

Lysergol $C_{16}H_{18}N_2O$

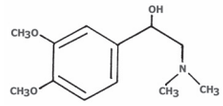


Crystals from ether; mp. 253-255°C.

Weakly psychedelic in limited human bioassays (Heimann 1965); shows CNS excitory effects in animals (Yui & Takeo 1958a, 1958b); partial agonist of 5-HT2a receptors, also affecting α1-adrenoceptors in the rat; strongly affects human 5-HT1dα- and 5-HT1dβ-receptors (Pertz 1996). Moderately resistant to heat degradation in bread-baking tests simulating **Ipomoea**-seed contaminated flour (Friedman & Dao 1990).

Macromerine $C_{12}H_{19}NO_3$

[α-[(dimethylamino)methyl]-3,4-dimethoxy-benzenemethanol; 1-(3,4-dimethoxyphenyl)-2-dimethylaminoethanol]

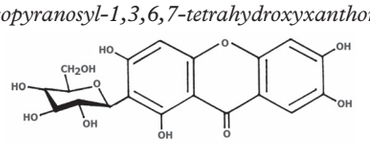


Crystals; mp. 66–67.5°C; sol. in ethanol, ether.

Claimed to be "hallucinogenic" in animals; 1/5 as potent as *mescaline*. Active 20mg/kg [i.p.] in cats and squirrel monkeys (Hodgkins et al. 1967). Using the conditioned avoidance response test on rats, *macromerine* was reported to be non-psychoactive [up to 100mg/kg of the hydrochloride, i.p.] (Vogel et al. 1973), though this needs further study [see *normacromerine*].

Mangiferin $C_{19}H_{18}O_{11}$

[euxanthogen; chinomine; alpizarin; 2-β-D-glucopyranosyl-1,3,6,7-tetrahydroxy-9H-xanthen-9-one; 2-C-β-D-glucopyranosyl-1,3,6,7-tetrahydroxyxanthone]

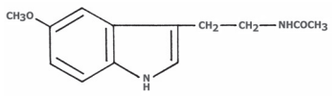


Pale yellow needles from ethanol aqueous soln.; mp. 270–272°C [dec.].

CNS stimulant in animals, weak MAOI, potentiates *morphine*-induced analgesia [mediated by *serotonin*] (Bhattacharya et al. 1972; Hostettmann & Wagner 1977); antiinflammatory, antiviral, antihepatotoxic (Harborne & Baxter ed. 1993). Widespread in angiosperms and ferns. Found in Mangifera indica, Gentiana spp., Iris spp., Salacia prenoides, Swertia spp., Aphloia madagascariensis, Athyrium mesosorum, Anemarrhena asphodeloides, Belamcanda chinensis, Hedysarum ussuriense, Hiptage madablota (Buckingham et al. ed. 1994; Harborne & Baxter ed. 1993; Hostettmann & Wagner 1977), Canscora decussata (Bhattacharya et al. 1972).

Melatonin $C_{13}H_{16}N_2O_2$

[N-acetyl-5-MeO-tryptamine; N-[2-(5-methoxy-1H-indol-3-yl)ethyl]acetamide]

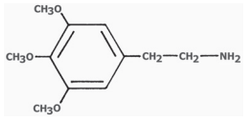


Pale yellow leaflets from benzene; mp. 116–118°C; sol. in ethanol/petroleum ether.

Hormone of pineal gland [also produced by other nerve tissues]. Antistress, immune-stimulant; synchronises brain electrical activity; regulates internal 'body-clock' and day/night rhythms [helping to alleviate symptoms of 'jet-lag']; helps induce sleep; powerful antioxidant; some weak MAOI-activity; modulates pituitary/adrenal axis, which modulate the other endocrines and organs of the body. Active in very small doses [0.5-3mg], though individual tolerances vary and some may need higher doses to benefit from *melatonin* supplementation. Orally-administered *melatonin* is rapidly absorbed from the gastrointestinal tract. Works best taken in evening or at night – morning or daytime doses may actually have the opposite effect, to the detriment of health. 50mg doses have been shown to increase REM sleep time, and increase intense colouration and vividness of dreams; has been known to cause visual imagery in the waking state. Can induce a feeling of well-being (Anton-Tay et al. 1971; Hagen & Cohen 1966; Hattori et al. 1995; Kveder & McIsaac 1961; Maurizi 1990; McKenna et al. 1984b; Pavel et al. 1980). Inhibits sexual activity (Crenshaw & Goldberg 1996). Stimulates hydroxyindole-O-methyltransferase [HIOMT] activity in bovine pineal (Hartley & Smith 1973). Potent skin-lightening agent. Can be converted to *6-methoxyharmalan* with removal of a molecule of water, though this remains to be demonstrated in vivo. Metabolised mostly to 6-OH-*melatonin*, as well as small amounts of 5-MeO-indoleacetic acid and an unidentified compound (McIsaac 1961). See *Neurochemistry*.

Mescaline $C_{11}H_{17}NO_3$

[TMPEA; 3,4,5-trimethoxyphenethylamine; 3,4,5-trimethoxybenzene-ethanamine]

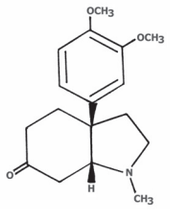


Crystals; mp. 35–36°C; bp. 180°C; moderately sol. in water; sol. in alcohol, chloroform, benzene; practically insol. in petroleum ether; takes up carbon dioxide from air and forms a crystalline carbonate.

Psychoactive at 100–200mg; fully psychedelic above 350mg; highest recorded human dose 1.5g. Minimum psychedelic dose 200–400mg with the sulphate salt, 180-260mg with the hydrochloride salt. Lasts 8–14hrs or more [depending on dose consumed] producing very colourful and vivid visions, accompanied by a usually-positive consciousness-expansion and mental clarity as well as strong stimulation. Psychedelic effects may take up to 2hrs or more to manifest, though strong doses are felt more rapidly. Initially causes nausea [usually], often with vomiting, after which the psychic phase of the experience comes to the fore (Fisher 1965; Kloesel 1958; Shulgin 1973; Shulgin & Shulgin 1991; pers. obs.). Stimulates hydroxyindole-O-methyltransferase [HIOMT] activity in bovine pineal (Hartley & Smith 1973). Lowers pulse and blood pressure; causes mydriasis. Agonist of postsynaptic 5-HT1a, 5-HT1b, 5-HT2a and 5-HT2c receptors [strongest at 5-HT2 types]; lowers *serotonin* levels; inhibits neuromuscular cholinergic transmission by blocking *acetylcholine* release; affects peripheral α-adrenergic receptors. LD50 in rats [i.p.] – 370mg/kg. Tolerance to the effects is rapidly developed, requiring at least several days between exposures to return normal response; cross-tolerance is also seen with *psilocybin* and LSD (Appel & Freedman 1968; Ghansah et al. 1993; Monte et al. 1997; Titeler et al. 1988; Trout & Friends 1999). Can be synthesised relatively easily [if you know what you're doing] from syringaldehyde, prepared by oxidation of lignin from Eucalyptus diversicolor ['karri'], E. obliqua ['messmate stringybark'] or E. regnans ['mountain ash'] (see Amos 1964). Controlled substance.

Mesembrine $C_{17}H_{23}NO_3$

[mesembranone; 3α-(3,4-dimethoxyphenyl)octahydro-1-methyl-6H-indol-6-one]

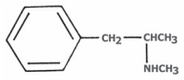


Pale yellow oil; bp. 186–190°C; freely sol. in alcohol, chloroform, acetone; slightly sol. in ether; practically insol. in benzene, petroleum ether, alkalis.

Psychological activity still unclear. For a long time said to be *cocaine*-like or *hyoscyamine*-like, based on assumptions, and some physiological effects noted from limited bioassays; structurally similar to crinane-class Amaryllidaceae alkaloids (Smith, M.T. et al. 1996). Recent bioassays of claimed pure *mesembrine* suggest its activity is the same as that of **Sceletium** tortuosum, in which it is found. Very potent; doses above 500mcg cause nausea, dizziness, and general discomfort (friendly pers. comm. 1999). Recently found to act as a *serotonin* re-uptake inhibitor [SRI]; *mesembrine* and its derivatives are claimed to be useful in treatment of depression, nervous anxiety, drug dependence, bulimia nervosa, and obsessive-compulsive disorders (Gericke & Van Wyk 1997).

Methamphetamine $C_{10}H_{15}N$

[N,α-dimethylbenzeneethanamine; d-N,α-dimethylphenethylamine; d-N-methylamphetamine; d-deoxy-ephedrine; d-desoxyephedrine; 1-phenyl-2-methylaminopropane; d-phenylisopr-opylmethylamine; methyl-β-phenylisopropylamine]

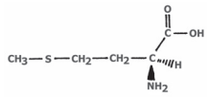


Methamphetamine HCl [$C_{10}H_{16}ClN$; speed; methedrine] – crystals, bitter taste; mp. 170–175°C; sol. in water, alcohol, chloroform; practically insol. in ether. A 1% aqueous soln. is neutral or slightly acid.

CNS stimulant, sympathomimetic. Can be prepared by reducing *ephedrine* or pseudoephedrine. More potent than *amphetamine* with similar pharmacology [see *amphetamine*], though at low to moderate doses the CNS effects are prominent and peripheral effects are not, unlike *amphetamine*. At higher doses, peripheral sympathomimetic effects are pronounced, including stimulation of cardiac output, increased blood pressure and vasoconstriction (Budavari et al. ed. 1989; Goodman & Gilman 1975; Julien 1995; Rothman et al. 2001). LD50 in mice [i.p.] – 70mg/kg (Budavari et al. ed. 1989). Controlled substance.

Methionine $C_5H_{11}NO_2S$

[2-amino-4-(methylthio)butanoic acid; 2-amino-4-(methylthio)butyric acid; γ-methylthio-α-aminobutyric acid]

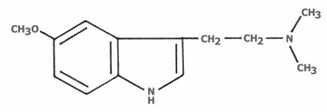


Minute hexagonal plates from dilute alcohol; mp. 280-283°C [dec., sealed capillary]; sol. in water, but crystals are water repellant at first; sol. in warm dilute alcohol; insol. in absolute alcohol, ether, petroleum ether, benzene, acetone.

Plays an important role in many biological methylations (Budavari et al. ed. 1989) [eg. *tryptamine* to *DMT*; see *Neurochemistry*, *Influencing Endogenous Chemistry*], particularly when metabolised with ATP to form SAM, an important methyl-donor (Cohen et al. 1974; Sprince 1970). Lipotropic, antiulcer, antidote (Buckingham et al. ed. 1994). May be toxic or poorly tolerated to people with liver diseases. 'Schizophrenics' given 20g a day for 1 week experienced behavioural changes and gastric distress; 'normal' people may tolerate large doses [10-20g a day] for short periods without incident (Harper 1973). Given with or without MAOI, *methionine* in varying doses "induced an acute florid psychotic reaction in 40% of schizophrenics tested". Caused behavioural changes and sleep disturbance when injected in mice and rats [250mg/kg a day for at least 21 days]; this was counteracted by co-administration of the amino acid l-serine. Metabolised to cysteine, homocysteine [convulsant] and/or cystathionine. Cysteine also apparently acts as a methyl-donor, producing urinary metabolites including N-methylated *serotonin*- and *tryptamine*-derivatives when given with an MAOI to schizophrenics, as well as exacerbating schizophrenic symptoms. Excess levels of dietary *methionine*, cysteine and/or homocysteine apparently encourage the metabolism of *tryptophan* to indoleacetic acid, rather than to N-methylated derivatives [*methionine* also competing with *tryptophan* for vitamin B6] – it seems that these amino acids may best be used for CNS effects by co-administration with an MAOI to ensure that any such desired derivatives are not immediately metabolised. dl-*Methionine* is less biologically-active than l-*methionine* (Beaton et al. 1975; Cohen et al. 1974; Sprince 1970). See *Neurochemistry*, *Influencing Endogenous Chemistry*.

5-Methoxy-DMT $C_{13}H_{18}N_2O$

[5-MeO-DMT; 5-methoxy-N,N-dimethyltryptamine; O-methylbufotenine; 3-[2-(dimethylamino)ethyl]-5-methoxyindole]



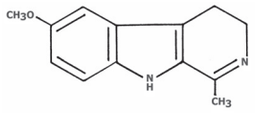
Prismatic crystals from hexane; mp. 66–68.5°C; sol. in ethanol, methanol, acetone, ether, dichloromethane, chloroform.

Active at 3.5–15mg smoked [vapourised], 10mg+ snuffed or sublingually, and 30mg+ orally. When vapourised, tremendous forceful 'rush' is felt almost immediately after inhalation, and the body becomes overwhelmingly sedated by the force; lateral vibrations in the visual field may be experienced at lower doses; visual effects not colourful or intricate as with *DMT*, though at doses around 10mg or more they are still very apparent, even to the extent that one may find one's-self in another physical place as real as 'normal' reality in every detail; some people are encompassed by a brilliant all-consuming white light; expansion of consciousness is usually experienced, though producing a more 'stoning' feeling at lower doses, or doses inefficiently administered. Despite the less vivid and colourful nature of the visual effects, this compound is much more powerful than *DMT*, with a good dose rocketing the subject beyond the realms of *DMT* to states of infinite submolecular cosmic conciousness, a full dose [ie. 10-20mg] vapourised and inhaled causing the user, as with *DMT*, to lose all contact with the physical world. Some find it comparable to 'near-death experience', and people sometimes think they have died or are dying while under the influence; rebirth from this state can be very pleasant. Doses above 10mg may produce nausea, vomiting, hypertension and unconsciousness accompanied by amnesia. Main effects last about 5 min. or less [longer when taken orally or sublingually], with return to 'baseline' after 1-2hrs. When combined with an MAOI such as *harmine* or *harmaline*, very unpleasant hypertensive and psychic effects have been experienced by some – it is advised that extreme care be taken with dosage via this route, and there might be a danger of *serotonin* syndrome with higher doses, due to the high affinity for 5-HT1a-receptors [see below, and *Influencing Endogenous Chemistry*]. Doses taken intranasally, sublingually or orally did not approach the full effects as experienced when vapourising the alkaloid, or when consuming it orally with an MAOI (Brush et al. 2004; Ott 2001b; Shulgin & Shulgin 1997; pers. obs.; pers. comms.). Effects are enhanced with pre-administration of small amounts of LSD (Trout & Friends 1999). Tolerance to the effects of repeated administrations does not seem to occur with *5-MeO-DMT* (Trout pers. comm.).

Potent agonist of 5-HT1a-receptors, and to a lesser extent 5-HT1b, 5-HT1c [5-HT2c], 5-HT2a [only slightly less potent binding than to 5-HT1a] & 5-HT2b receptors (McKenna et al. 1990; Peroutka 1986; Strassman et al. 1996; Winter et al. 1999b, 2000). Less potent in brain than *bufotenine*, though more potent overall due to its ease in crossing the blood-brain barrier (McBride 2000). Causes *norepinephrine*-release in in-vitro animal tests. Has MAO-A inhibiting activity in vitro, less potent than that of *DMT* (Ghosal 1972; Ho et al. 1970; McKenna et al. 1984b; Reimann & Schneider 1993). Stimulates hydroxyindole-O-methyltransferase [HIOMT] activity in bovine pineal (Hartley & Smith 1973). O-Demethylated by the P450 enzyme CYP2D6 (Yu et al. 2003). Endogenous mammalian neurochemical (Corbett et al. 1978; Guchhait 1976; Mandel & Walker 1974; Smythies et al. 1979; Tanimukai et al. 1970). Is orally-active in sheep at 40mg/kg; one sheep died 50 min. after being given a dose of 85mg/kg (Bourke et al. 1988). Controlled substance in some countries [Australia]. See *Neurochemistry*.

6-Methoxyharmalan $C_{13}H_{14}N_2O$

[6-methoxy-3,4-dihydro-1-methyl-β-carboline; 6-MeO-DHH; 10-methoxyharmalan]

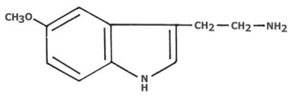


Crystals; mp. 208–209°C.

MAOI of similar potency to *leptaflorine* in rat liver (Buckholtz & Boggan 1977; Kim et al. 1997; McKenna et al. 1984a). Has been used in conjunction with *5-methoxy-DMT* to produce psychedelic effects (Leuner & Schlichting 1990). Appears to be psychoactive in rats [1mg or less] (McIsaac 1961; McIsaac et al. 1961). Caused mild psychotropic effects at 1.5mg/kg; said by Naranjo to be 'hallucinogenic'; slightly more active than *harmaline*. Powerful *serotonin* antagonist more potent than *harmaline*, slightly less potent than LSD (Glennon 1981; McIsaac et al. 1961; Naranjo 1967). Possibly a mammalian pineal neurochemical derived from cyclodehydration of *melatonin*. Shows skin-lightening activity the same as that of *melatonin* (McIsaac 1961). See *Neurochemistry*.

5-Methoxytryptamine $C_{11}H_{14}N_2O$

[5-methoxy-1H-indole-3-ethanamine; 3-(2-aminoethyl)-5-methoxyindole; meksamin; mexamine]

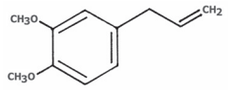


Crystals from ethanol; mp. 120–122°C; sol. in benzene, ethanol, chloroform.

Potentiates hypnotics and sedatives; more active than *serotonin* (Budavari et al. ed. 1989). Oxytocic. Reported to be 'psychotomimetic'; this probably is an extrapolation of the 'behavioural disturbance' observed in rats, which was in the same level of potency as *bufotenine*. Mammalian pineal neurochemical, also found in blood and urine; biological precursor to *melatonin*, *5-methoxy-DMT* (Banerjee & Snyder 1973; Beck & Jonsson 1981; Bosin & Beck 1979; Corbett et al. 1978; Gessner et al. 1961; Kveder & McIsaac 1961; Pevet 1983; Relkin 1983; Vogel 1969). Normally metabolised mainly to 5-MeO-indoleacetic acid (McIsaac 1961). May be O-demethylated by the P450 enzyme CYP2D6 (Yu et al. 2003). Agonist of 5-HT1a & 5-HT1d receptors; also affects 5-HT1b & 5-HT1c [5-HT2c] receptors (Peroutka 1986, 1993). MAOI in rat liver, of similar potency to *5-methoxy-DMT* (McKenna et al. 1984b). Protects against radiation (Shulgin & Shulgin 1997). See *Neurochemistry*.

Methyleugenol $C_{11}H_{14}O_2$

[O-methyleugenol; eugenol methyl ether; 4-allyl-veratrole; 4-allyl-1,2-dimethoxybenzene; 1,2-dimethoxy-4-(2-propenyl)benzene; 3,4-dihydroxyallylbenzene dimethyl ether]

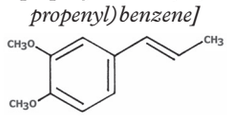


Oil; bp. 255°C; sol. in hexane, organic solvents.

CNS depressant, spasmolytic, skeletal muscle relaxant, hypothermic (Harborne & Baxter ed. 1993). Non-amine precursor to 3,4-DMA [see *eugenol*] (Shulgin et al. 1967).

Methylisoeugenol $C_{11}H_{14}O_2$

[3,4-dimethoxy-1-propenylbenzene; 1,2-dimethoxy-4-(1-propenyl)benzene]

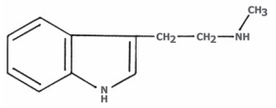


Normally isolated as a mix of E and Z isomers. Oil; mp. 16–17°C; bp. 138-140°C; sol. in hexane, organic solvents.

Non-amine precursor to 3,4-DMA [see *eugenol*] (Shulgin & Shulgin 1991).

N-Methyltryptamine $C_{11}H_{14}N_2$

[NMT; dipterine; N-methyl-1H-indole-3-ethanamine; 3-(2-methylaminoethyl)indole]

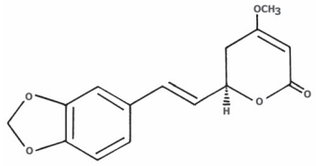


Prisms from petroleum ether; mp. 87–90°C; sol. in light petroleum, benzene, chloroform, ethanol/water.

Inactive at doses attempted orally; claimed to be active by smoking at 50-100mg, producing visual effects lasting only about 15 seconds, in one psychonaut. Mammalian neurochemical (Axelrod 1961; Corbett et al. 1978; Oon et al. 1977; Shulgin & Shulgin 1997); MAOI in rat liver, slightly more potent than *5-methoxy-DMT* (McKenna et al. 1984b). See *Neurochemistry*.

Methysticin $C_{15}H_{14}O_5$

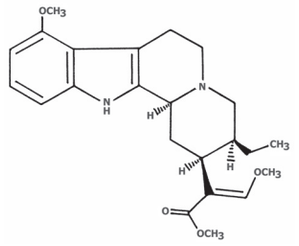
[6-[2-(1,3-benzodioxol-5-yl)ethenyl]-5,6-dihydro-4-methoxy-2H-pyran-2-one; 4-methoxy-6-(3,4-methylenedioxystyryl)-5,6-dihydropyran]



Crystals from methanol; mp. 132–134/139–140.5°C; practically insol. in water; sol. in alcohol, ether, acetone.

Muscle-relaxant, anticonvulsant, anaesthetic, sedative hypnotic; potentiates barbiturate-induced sleep. Causes ataxia in high doses (Buckley et al. 1967; Keller & Klohs 1963; Klohs 1967; Meyer 1967); protects against tissue damage from inadequate blood flow (Singh & Blumenthal 1997). Inhibits *norepinephrine*-uptake in rat brain (Seitz et al. 1997); MAO-B inhibitor in human platelets, slightly less potent than *5,6-dehydrokawain* in this regard (Uebelhack et al. 1998).

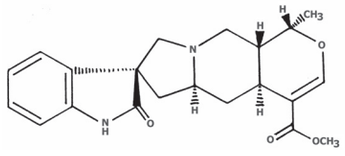
Mitragynine $C_{23}H_{30}N_2O_4$



White amorphous powder; mp. 102–106°C; bp. 230–240°C; sol. in alcohol, chloroform, acetic acid.

General depressant, analgesic, antitussive (Macko et al. 1972); affects μ- and δ-opioid receptors, and possibly also α2-adrenoceptors and 5-HT2a receptors (Matsumoto et al. 1997; Thongpradichote et al. 1998; Watanabe et al. 1997).

Mitraphylline $C_{21}H_{24}N_2O_4$

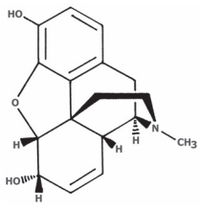


White needles from ethanol; mp. 265–266°C; sol. in methanol, ethyl acetate, ether.

Weak CNS depressant, hypotensive (Harborne & Baxter ed. 1993).

Morphine $C_{17}H_{19}NO_3$

[meconium; 7,8-didehydro-4,5-epoxy-17-methylmorphinan-3,6-diol]

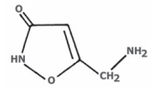


Short orthorhombic columnar prisms from anisole; mp. 254–256.4°C [dec. 254°C]; also, a metastable phase, mp. 197°C; high-melting form sublimes 190–200°C; the amorphous or freshly precipitated form is more sol.; sol. in ethyl acetate, alcohol, or mix of chloroform and alcohols; moderately sol. in boiling water, chloroform; slightly sol. in ether, ammonia, benzene; freely sol. in solns. of fixed alkali and alkaline earth hydroxides, in phenol, cresols, boiling methanol.

Powerful narcotic, analgesic, euphoriant, tranquilliser, anxiolytic, respiratory depressant, antitussive, miotic. Horse stimulant. Hyperalgesic when injected into rat brainstem. Causes constipation. Can cause nausea and vomiting, and itching due to *histamine*-release. Opiate receptor agonist, particularly potently binding to mu-receptors; indirectly stimulates *dopamine* release. Lowers testosterone levels. Can be dangerously potentiated by alcohol, barbiturates, tricyclic antidepressants, MAOIs. Highly addictive; causes withdrawal symptoms, including runny nose, sweating, crying, goosebumps, muscle twitching, cramps, anorexia, insomnia, vomiting and diarrhoea. Does not cross the blood-brain barrier as easily as heroin [diacetylmorphine], due to its low lipid-solubility. Therapeutic dose is 5–30mg [oral tablets], 8–15mg [s.c.] or 10–20mg [i.m.]. Lethal oral dose in humans probably 120–250mg, though people have wide variation in tolerance. Addicts, people in pain, and those with hyperthyroidism can tolerate higher doses, and 20–300mg or more have been used 'recreationally' [some addicts take more than 1000mg daily]. If death occurs it is usually as a result of respiratory failure (Beckman 1961; Goodman & Gilman 1975; Gosselin et al. 1976; Hamann & Martin 1994; Julien 1995; Preininger 1975). Endogenous mammalian neurochemical (Brossi 1993; Cardinale et al. 1987), also found in human and cow milk (Hazum et al. 1981). Controlled substance. See *Neurochemistry*.

Muscimol $C_4H_6N_2O_2$

[pantherine; agarin; pyro-ibotenic acid; 5-(aminomethyl)-3(2H)-isoxazolone]

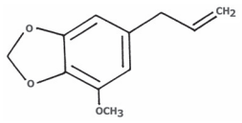


Crystals from ethanol; mp. 174–176°C [dec.]; in solid phase, exists as a betaine.

Active at 10–15mg, producing dizziness, ataxia, mood elevation, psychic stimulation [10mg dose], impaired concentration [15mg dose], visual and auditory distortions, "disorientation in situation and time", and muscle twitching, followed by brief sleep. Effects after this point were varied; with the 10mg dose, the subject felt "normal, rested and able to undertake anything", though with the 15mg dose he felt "dull and uncertain". An interesting effect from the pre-sleep phase was described – "Vision was altered by endlessly repetitioned echo-pictures of situations a few minutes before". Small doses [5mg] improved concentration (Waser 1967). Potent *GABA*-a receptor agonist, inhibits *GABA* binding; reduces neuronal excitability (Johnston et al. 1968; Mousah et al. 1986). Blocks phencyclidine [PCP]-induced behavioural stimulation (Tunnicliff 1998). Increased brain levels of *serotonin* and *dopamine* in rodents [i.p.]. May be metabolised by GABA transaminase (Michelot & Melendez-Howell 2003). LD50 in mice – 3.8mg/kg [s.c.], 2.5mg/kg [i.p.]; in rats – 4.5mg/kg [i.v.], 45mg/kg [oral] (Budavari et al. ed. 1989).

Myristicin $C_{11}H_{12}O_3$

[4-MeO-6-(2-propenyl)-1,3-benzodioxole; 1-MeO-2,3-methylenedioxy-5-(2-propenyl)benzene; 1-allyl-3-MeO-4,5-methylenedioxybenzene]

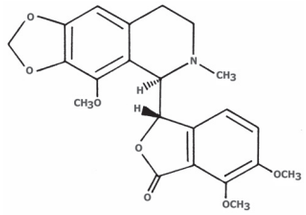


Colourless oil; bp. 95–97/149–149.5/173°C; sol. in hexane, organic solvents.

Psychoactive at 400mg in 6 out of 10 human bioassayists (Shulgin et al. 1967). May be an MAOI (Truitt et al. 1963). Narrow-spectrum insecticide (Buckingham et al. ed. 1994). Non-amine precursor to MMDA [3-methoxy-4,5-methylenedioxy-*amphetamine*], which is psychoactive at 100-250mg, and is a mild psychedelic similar in some ways to MDA, but gentler (Shulgin 1973; Shulgin et al. 1967; Shulgin & Shulgin 1991). Whether or not the presumed in vivo metabolism to amphetamines actually occurs has been under question. Rats were shown to metabolise it predominantly to 3-piperidyl-1-(3'-MeO-4',5'-methylenedioxyphenyl)-1-propanone; guinea pigs metabolised it predominantly to 3-pyrrolidinyl-1-(3'-MeO-4',5'-methylenedioxyphenyl)-1-propanone [these might also prove to be psychoactive] (Oswald et al. 1971b). However, in support of the hypothesis, a later study found rat liver to produce MMDA from *myristicin*, after a 5hr incubation; the reaction was enhanced under oxidative conditions (Braun & Kalbhen 1973). MMDA is a controlled substance.

Narcotine $C_{22}H_{23}NO_7$

[noscapine; opianine; 6,7-dimethoxy-3-(5,6,7,8-tetrahydro-4-methoxy-6-methyl-1,3-dioxolo[4,5-g]isoquinolin-5-yl)-1(3H)-isobenzofuranone]

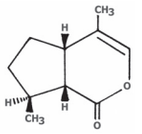


The (1R,9S)-form is the natural form [(-)-α-narcotine]. Stout needles from ethanol, or orthorhombic bisphenoidal prisms from diacetone; mp. 176°C; sublimes at 150–160°C under pressure; triboluminescent; slightly sol. in ammonium hydroxide, hot solns. of potassium hydroxide and sodium hydroxide, forming salts; salts formed with acids are dextrorotatory and unstable in water. *Narcotine* is a very weak base forming unstable salts with acids and strong bases. Readily epimerises to (-)-β-*narcotine*.

Analgesic, sedative, smooth muscle relaxant; antitussive, with similar potency to *codeine*. Active therapeutically at 25–50mg [as the HCl]; the β-isomer is more potent than the α-isomer (Buckingham et al. ed. 1994; Preininger 1975).

Nepetalactone $C_{10}H_{14}O_2$

[5,6,7,7a-tetrahydro-4,7-dimethyl-cyclopenta[c]pyran-1(4aH)-one]

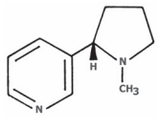


Oil; a mix of the cis-trans (shown) and trans-cis isomers [the cis-trans being 70–99% of the oil]; bp. 71–72°C; sol. in ether, carbon tetrachloride.

Cat attractant; sex attractant for aphids (Buckingham et al. ed. 1994; Tucker & Tucker 1988). Psychoactive constituent of catnip, **Nepeta** cataria (Harney et al. 1974, 1977).

Nicotine $C_{10}H_{14}N_2$

[3-(1-methyl-2-pyrrolidinyl)pyridine; 1-methyl-2-(3-pyridyl)pyrrolidine]



Colourless to pale yellow oily liquid, very hygroscopic, turns brown on exposure to air or light, acrid burning taste; bp. 123–125/246.1–247°C [partial dec.]; volatile with steam; miscible with water below 60°C; on mixing *nicotine* with water, the volume contracts; very sol. in alcohol, chloroform, ether, petroleum ether, kerosene, oils. Forms salts with almost any acid and double salts with many metals and acids. Base is readily absorbed through mucous membranes and intact skin; salts are not.

Tranquilliser, CNS-stimulant, memory and cognitive enhancer, anorexic. Activates nicotinic *acetylcholine*-receptors, and causes *acetylcholine* and catecholamine release [including *epinephrine* and *dopamine*], also stimulating muscarinic *acetylcholine*-receptors. After initial excitation, it

acts as a depolarising nicotinic-blocker; increases cortisol, *dehydroepiandrosterone* and progesterone levels, decreases *serotonin* levels. NMDA-receptor antagonist. Decreases blood flow to brain and penis; can cause impotence. Can cause nausea, vomiting, dizziness, sweating, salivation, headache, evacuation of bowel and bladder, weakness, mental confusion, twitching, convulsions, unconsciousness and respiratory paralysis in high doses. Highly toxic; treatment must be quick to be effective. Fatal human dose c.50–60mg. (+)-*Nicotine* is a more potent respiratory depressant than (-)-*nicotine*, and is much less potent than (-)-*nicotine* as a central stimulant; both are equipotent in their potential lethality. Orally, the base form is more toxic than the salt form. Addictive; can cause withdrawal symptoms including irritability, aggression, depression, impaired concentration, tremors (Aizenman et al. 1991; Barlow & McLeod 1969; Byrne 1988; Clarke 1990; Crenshaw & Goldberg 1996; Decker et al. 1993; Goodman & Gilman 1975; Julien 1995; Kruk & Pycock 1983; Reavill et al. 1990; Sabelli & Giardina 1972; Sloan et al. 1988; Terry et al. 1993; Watt & Breyer-Brandwijk 1962). Also found in Arum maculatum, Asclepias syriaca, Cyphomandra spp., Equisetum palustre (Rätsch 1998), Sempervivum arachnoideum (Paris & Frigot 1959), Sedum spp., Eclipta alba [see *Endnotes*] and Zinnia spp. (Pal & Narasimham 1943; Rimpler 1965).

Nitrous oxide N_2O

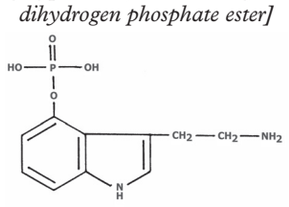
['nitrous'; laughing gas; dinitrogen oxide]

Colourless gas; mp. –91°C; bp. –88.5°C; dec. to N_2 and O_2 over 500°C. Can be detonated.

Mild and short-lasting anaesthetic when inhaled in small to moderate amounts [mixed with oxygen – preferably 40% nitrous oxide, 60% oxygen]; inhalation also reveals euphoric and dissociative/psychedelic activity with several lungfuls or more – this action is greatly potentiated by drugs such as *THC*, *mescaline*, *psilocin* and LSD. Strong dysphoric experiences are rare, but do occur; in any case, the effects are very short-lived after ceasing inhalation of the gas (pers. obs.; Atkinson et al. 1979). Higher doses act as a general depressant and anaesthetic/analgesic; when used for light surgical anaesthesia, 50–70% nitrous oxide is used. Concentrations higher than this can be dangerous to inhale. Sufficient oxygen must also be inhaled, mixed with the nitrous oxide, as well as breaths of air taken between lungfuls of nitrous oxide/oxygen (Atkinson et al. 1979; Goodman & Gilman 1975); deaths have occurred from hypoxaemia and asphyxiation, due to insufficient co-inhalation of oxygen (Temple et al. 1997; Winek et al. 1995). Other hazards of inhaling nitrous oxide from pressurised canisters or tanks include frostbite to skin exposed to the cold gas (Hwang et al. 1996); this is a further reason to mix the nitrous oxide with air in a balloon before inhaling, or at least to not inhale directly from the outlet of the tank. However, nitrous oxide is frequently inhaled through whipped-cream dispensers [without the cream] without frostbite. This is most likely because after being ejected under pressure from the whipped-cream bulb, the nitrous oxide is able to cool somewhat within the dispenser before it is inhaled (pers. obs.). Can be harmful to health with excessive and continued use, resulting in reduced white blood cells, reduced blood platelets and/or megaloblastic anaemia; generally, a syndrome of myelopathy or myeloneuropathy [a disease of the spinal cord] occurs, due to inactivation of vitamin B12 and dependent enzymes. Easily observable symptoms of chronic abuse may include weakness in lower limbs, ataxic gait, depression and memory loss. Neurological symptoms have been treated successfully by adminstration of *methionine* and vitamin B12, or hydroxocobalamin and folate supplements (Butzkueven & King 2000; Lai et al. 1997; Pema et al. 1998; Temple et al. 1997). Full mode of action unclear; appears to act as an NMDA-receptor antagonist, and inhibits ionic currents; also inhibits NMDA-mediated neurotoxicity, and has some neurotoxicity of its own, which is prevented by *GABA* activity (Jevtovic-Todorovic et al. 1998).

Norbaeocystin $C_{10}H_{13}N_2O_4P$

[norbaeocystine; bis-desmethylpsilocybin; 4-phosphoryloxytryptamine; 3-aminoethyl-1H-indol-4-ol dihydrogen phosphate ester]

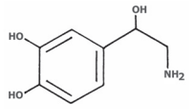


Crystals; mp. 188–192°C; sol. in water, methanol.

Thought to be psychoactive, possibly after dephosphorylation to 4-OH-*tryptamine* (Ott 1993).

Norepinephrine $C_8H_{11}NO_3$

[l-noradrenaline; NE; levarterenol; l-arterenol; 4-(2-amino-1-hydroxyethyl)-2-benzenediol; α-(aminomethyl)-3,4-dihydroxybenzyl alcohol; 2-amino-1-(3,4-dihydroxyphenyl)ethanol; 4-(β-amino-α-hydroxyethyl)catechol]

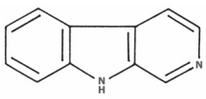


Microcrystals from water; mp. 216.5–218°C [dec.]; dl-form sparingly sol. in water; very slightly sol. in alcohol, ether; sol. in dilute acids; l-form HCl freely sol. in water.

Adrenergic, sympathomimetic, bronchodilator, antihypotensive, vasopressor (Buckingham et al. ed. 1994; Budavari et al. ed. 1989). Greater CNS stimulant activity than *epinephrine*, weaker PNS effects. Inhibits tyrosine hydroxylase. Human neurotransmitter (Goodman & Gilman 1975; Julien 1995; Kaplan & Sadock 1989; Kruk & Pycock 1983; Moore 1978); does not cross the blood-brain barrier (Marley & Stephenson 1972). May be metabolised to nor-*adrenochrome* (Hoffer & Osmond 1960). Also in Portulaca oleracea [c.0.2% w/w] and Phaseolus multiflorus (Lundstrom 1989). See *Neurochemistry*.

Norharman $C_{11}H_8N_2$

[β-carboline; 2-carboline; 9H-pyrido[3,4-b]indole]

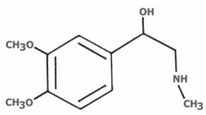


Crystals; mp. 198.5° C; sol. in hot water; sparingly sol. in petroleum ether.

MAOI more potent, or less potent [depending on which study you read] than *harman* in liver, and less so in brain (Buckholtz & Boggan 1977; Kim et al. 1997; McKenna et al. 1984a; Udenfriend et al. 1958); binds to MAO-B (May et al. 1994); inhibits plasma cholinesterase (Orgell 1963a); BZ-receptor antagonist, and initially a sedative [later potentiating convulsive activity] at 20mg/kg [i.p.] in rats (Morin 1984); partial agonist of muopiate receptors. Can inhibit symptoms of *morphine* withdrawal syndrome (Cappendijk et al. 1994). Inhibits AChE and non-competitively inhibits muscarinic *acetylcholine*-receptor binding in rat brain (Skup et al. 1983). Catatonic motor-depressant in rats [10mg/kg]; convulsant in higher doses [50mg/kg] (Ho 1977). Causes locomotor-effects in sheep (Harborne et al. ed. 1996); plant growth inhibitor; potentiates benzopyrene-induced mutagenesis. Mammalian neurochemical (Buckingham et al. ed. 1994; Collins 1983); may be metabolised by mice [given 0.5mmol/kg i.p., twice a day for 1 week] to the neurotoxin 2,9-N,N-dimethylnorharmanium cation, which is implicated in Parkinson's Disease (Matsubara et al. 1998). See *Neurochemistry*.

Normacromerine $C_{11}H_{17}NO_3$

[N-demethylmacromerine; N-methyl-3,4-dimethoxy-β-hydroxyphenethylamine; N-methyl-3,4-dimethoxyphenethanolamine]

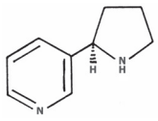


Needle-shaped slightly yellow crystals or brown gum; mp. 101-103°C; sol. in ethanol, chloroform.

Reported in an early study to be non-psychoactive, due to no observed effect on the conditioned avoidance response test in rats [up to 100mg/kg of the hydrochloride, i.p.] (Vogel et al. 1973); appears to be psychoactive in rats [up to 20mg/kg i.p.] using more complex testing methods, with comparisons made to *mescaline* and *psilocybin* (Bourn et al. 1978). Human pharmacology unknown.

Nornicotine $C_9H_{12}N_2$

[3-(2-pyrrolidinyl)pyridine; 2-(3-pyridyl)pyrrolidine]

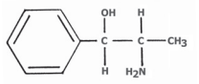


Viscous liquid, hygroscopic; develops a slight amine odour, less pungent than that of *nicotine*; bp. 105–107/117°C; miscible with water; very sol. in alcohol, chloroform, ether, petroleum ether, kerosene, oils. Less volatile and less easily oxidised than *nicotine*.

Roughly 1/3 as toxic as *nicotine*, with similar activity; can also cause faintness, muscular weakness, prostration, severe nausea, vomiting, diarrhoea, and collapse with or without convulsions (Budavari et al. ed. 1989). Also found in Salpiglossis sinuata, which contained over 0.01% alkaloids in roots and branches, including *nornicotine* (Schröder 1958).

Norpseudoephedrine $C_9H_{13}NO$

[cathine; norisoephedrine]

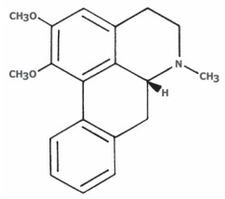


Plates from methanol; mp. 77.5–78°C; freebase strongly alkaline; sol. in alcohol, chloroform, ether, dilute acids.

CNS stimulant more potent than *ephedrine*; anorexic (Kalix 1991).

Nuciferine $C_{19}H_{21}NO_2$

[sanjoinine E; 1,2-dimethoxyaporphine]

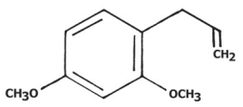


Crystals; mp. 165.5°C; sol. in methanol, chloroform, 2-propanol.

Strong sedative; inhibits adenylate cyclase (Buckingham et al. ed. 1994); neuroleptic activity similar to chlorpromazine in animals; potentiates *morphine* analgesia. Blockades *dopamine* receptors as an antagonist (Bhattacharya et al. 1978; Castedo & Tojo 1990); appears to have some anticholinergic activity (Zelenski 1977). Also found in Colubrina faralaotra [see also **Nelumbo**] (Buckingham et al. ed. 1994).

Osmorrhizole $C_{11}H_{14}O_2$

[osmorhizole; 2,4-dimethoxy-1-(2-propenyl)benzene; 2,4-dimethoxyphenylprop-2-ene; 1-allyl-2,4-dimethoxybenzene]



Bp. 71-73°C; sol. in hexane/benzene.

Non-amine precursor to 2,4-DMA [2,4-dimethoxy-*amphetamine*]; 2,4-DMA shows threshold psychoactivity at c.60mg, lasting c.3hrs, and qualitatively *amphetamine*-like with hints of dissociation. This alkaloid has not been explored much and caution is advised with higher doses (Shulgin & Shulgin 1991).

Oxytocin $C_{43}H_{66}N_{12}O_{12}S_2$

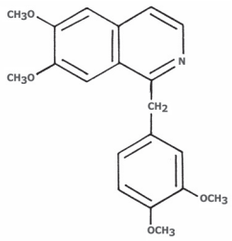
[L-cysteinyl-L-tyrosyl-L-isoleucyl-L-glutaminyl-L-asparaginyl-L-cysteinyl-L-prolyl-L-leucylglycinamide cyclic (1→6)disulfide]

White powder.

Oxytocic (Buckingham et al. ed. 1994); speeds uterine contractions in labour, and controls milk ejection (Kruk & Pycock 1983). Released in large amounts at orgasm; indirectly causes pleasure and sedation, enhances bonding through touch. May be involved in male post-coital inertia. Increases levels of *dopamine*, *vasopressin*, *epinephrine*, *serotonin*, prolactin, prostaglandin, VIP, LHRH, testosterone and oestrogen [in women]; stimulates α-adrenergic and cholinergic activity. Poorly absorbed orally; usually taken as a nasal spray or injected. Mammalian hormone (Crenshaw & Goldberg 1996).

Papaverine $C_{20}H_{21}NO_4$

[papaveroline tetramethyl ether; 6,7-dimethoxy-1-(3,4-dimethoxybenzyl)isoquinoline]

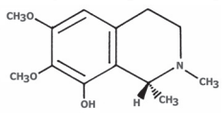


Triboluminescent orthorhombic prisms from alcohol and ether; mp. 147–148°C; sublimes 135–140°C under pressure; almost insol. in water; sol. in hot benzene, glacial acetic acid, acetone; slightly sol. in chloroform, petroleum ether. Stores best in soln. at pH 2–2.8.

Sedative; analgesic, weaker but longer-lasting than *morphine*; smooth muscle relaxant, cerebral vasodilator, antiasthmatic, antispasmodic. Phosphodiesterase-inhibitor, increasing cAMP levels; anticholinesterase. Initially stimulates respiration and increases blood pressure, later reversing these effects (Buckingham et al. ed. 1994; Budavari et al. ed. 1989; Goodman & Gilman 1975; Preininger 1975). Has shown neurotoxicity to dopaminergic neurons in vitro, as has tetrahydropapaverine to a lesser degree. Both have been tentatively proposed to be formed endogenously – tetrahydropapaverine from oxidation of the oxidative metabolite of *DMPEA* [dimethoxyphenylaldehyde], and *papaverine* from oxidation of tetrahydropapaverine – though this has not been demonstrated (Goto et al. 1997; Koshimura et al. 1997). Medicinal dose [oral] – 30–200mg (Goodman & Gilman 1975). LD50 in mice [i.v.] – 25mg/kg (Buckingham et al. ed. 1994).

Pellotine $C_{13}H_{19}NO_3$

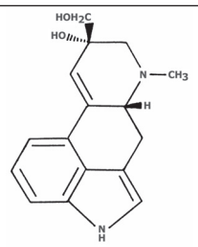
[peyotline; 1,2,3,4-tetrahydro-8-hydroxy-6,7-methoxy-1,2-dimethylisoquinoline; 1,2,3,4-tetrahydro-6,7-dimethoxy-1,2-dimethyl-8-isoquinolinol]



Crystals or plates from ethanol or petroleum ether; mp. 111–112°C.

Sedative at 15–30mg; soporific above 50mg (Bruhn & Holmstedt 1974; Shulgin 1973). 'Disorientation and hallucinations' have been experienced by a human with a dose of 300mg (Robles & Robleda 1931). Hypotensive and convulsant in animals (Kloesel 1958); 5–10mg caused convulsions in frogs, dogs and cats (Kapadia & Fayez 1970).

Penniclavine $C_{16}H_{18}N_2O_2$

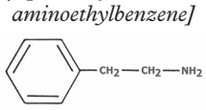


Crystals; mp. 222–225°C [dec.]; sol. in chloroform.

CNS excitory effects in animals (Yui & Takeo 1958a, 1958b).

Phenethylamine $C_8H_{11}N$

[2-phenylethylamine; β-phenethylamine; benzeneethanamine; β-aminoethylbenzene]

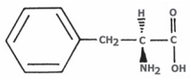


Liquid, fishy odour, strong base; bp. 194.5–195/197–198°C; sol. in water; freely sol. in alcohol and ether; absorbs carbon dioxide from air.

CNS stimulant like *amphetamine* when injected in high doses, or when given with an MAOI. Generally inactive orally (Boulton & Juorio 1982; Saavedra 1989; Sabelli et al. 1978; Squires 1978; Webster 1989). Skin irritant (Budavari et al. ed. 1989). Might cause tachycardia, anxiety, nausea and vomiting (Beck et al. 1998), but it has been given to humans to treat depression [10-60mg a day, with 10mg selegiline (l-deprenyl, an MAO-B inhibitor); successful in 60% of patients] with no side effects noted (Sabelli et al. 1996). Can cause severe migraine. Endogenous mammalian neurochemical, biosynthesised from l-*phenylalanine*. Readily crosses blood-brain barrier but is rapidly metabolised. If metabolised by *dopamine*-β-hydroxylase, phenylethanolamine is formed [a mild stimulant]; if metabolised by MAO-B [the preferred route], phenylacetaldehyde is formed [a sedative] (Boulton & Juorio 1982; Kruk & Pycock 1983; Sabelli & Giardina 1970; Sabelli et al. 1978). Brain content and/or turnover is increased by alcohol, **Cannabis**, opiates and *amphetamines* (Sabelli et al. 1978); behavioural effects are potentiated with *serotonin*-receptor blockade (Beck et al. 1998). See *Neurochemistry*.

Phenylalanine $C_9H_{11}NO_2$

[β-phenylalanine; α-aminobenzenepropanoic acid; 2-amino-3-phenylpropanoic acid]

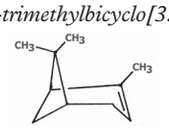


Natural L-form – monoclinic plates or leaflets from warm concentrated aqueous solns.; hydrated needles from dilute solns.; mp. 283–284°C [dec.]; sublimes in vacuo; sol. in water, more so as temp. increases; very slightly sol. in alcohol.

Biosynthetic precursor to tyrosine and/or *phenethylamine*; increases brain *phenethylamine* levels (Boulton & Juorio 1982). Antidepressant (Sabelli et al. 1978). Increases *tribulin* levels in rat brain (Bhattacharya et al. 1991a). Individuals with the disorder phenylketonuria [PKU] are unable to biosynthetically convert *phenylalanine* to tyrosine due to a defect in the function of the enzyme *phenylalanine* hydroxylase. This buildup of *phenylalanine* and metabolites such as *phenethylamine*, phenylpyruvic acid [interferes with *serotonin* metabolism] and phenylacetic acid often results in severe mental retardation (McIsaac 1961; Nyhan 1987; Sabelli et al. 1978). However, people without this disorder have consumed 20g a day [oral] with no adverse effects (Harper 1973). See *Neurochemistry*.

α-Pinene $C_{10}H_{16}$

[2-pinene; 2,6,6-trimethylbicyclo[3.3.1]-hept-2-ene]

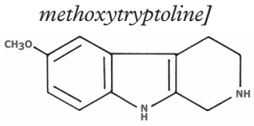


DL-form liquid, characteristic odour of turpentine; bp. 155–156°C; practically insol. in water; sol. in alcohol, chloroform, ether, glacial acetic acid. Oil of turpentine is 58–65% α-*pinene*, 30% β-*pinene*.

Flavouring ingredient, intermediate in manufacture of synthetic perfumes (Buckingham et al. ed. 1994). Irritates skin, mucous membranes; causes delirium, ataxia, kidney damage, coma. Inhalation causes nervous disturbances, dizziness, chest pain, palpitations, bronchitis and nephritis. Chronic contact can cause benign skin tumours. Absorbed through skin, lungs and intestine (Budavari et al. ed. 1989; Harborne & Baxter ed. 1993).

Pinoline $C_{12}H_{14}N_2O$

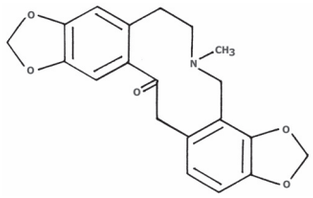
[6-methoxy-THβC; 1,2,3,4-tetrahydro-6-methoxy-β-carboline; methoxytryptoline]



Potent inhibitor of MAO-A in rat brain; elevates brain *serotonin*, and blocks its uptake (Buckholtz & Boggan 1977; Ho et al. 1968; McIsaac et al. 1972; Meller et al. 1977); inhibits binding of leu-*enkephalin* to delta opiate-receptors (Airaksinen et al. 1984). Potent antioxidant (Cheve et al. 2002). O-Demethylated by the P450 enzyme CYP2D6 (Yu et al. 2003). Endogenous mammalian neurochemical, found in high levels in human pineal gland (Langer et al. 1984; McIsaac et al. 1972). See *Neurochemistry*.

Protopine $C_{20}H_{19}NO_5$

[fumarine; corydinine; corydalis C; biflorine; macleyine; 4,6,7,14-tetrahydro-5-methylbis[1,3]benzodioxolo[4,5-c:5',6'-g]azecin-13(5H)-one]

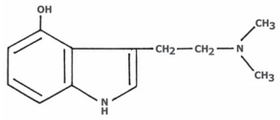


Monoclinic prisms from alcohol and chloroform; mp. 207–208°C; moderately sol. in ether; slightly sol. in ethyl acetate, benzene, petroleum ether; practically insol. in water.

Sedative, weak spasmolytic, lowers blood pressure and retards heart at low doses; excitant and convulsant in higher doses; smooth muscle stimulant or relaxant; weak antitumour activity, bactericidal (Buckingham et al. ed. 1994; Harborne & Baxter ed. 1993; Preininger 1975). Has anticholinergic activity (Capasso et al. 1997).

Psilocin $C_{12}H_{16}N_2O$

[psilocine; 3-(2-dimethylaminoethyl)-4-hydroxyindole; 3-(2-dimethylaminoethyl)-1H-indol-4-ol; 4-hydroxy-N,N-DMT; 4-OH-DMT]

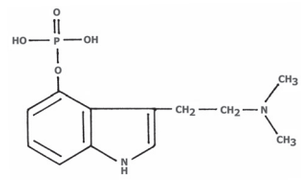


Plates from methanol; mp. 173–176°C [dec.]; very slightly sol. in water [more so in acidified water]; slightly sol. in methanol; seems to be most sol. in 75% aqueous ethanol. Unstable in soln., especially alkaline soln. Functions as an acid or a base; formed by metabolic dephosphorylation of *psilocybin*.

Active from 2-4mg; psychedelic above 6mg, lasting 4-8hrs; reportedly some 1.4x as potent as *psilocybin*. Lower doses produce physical sedation, restlessness, intense psychological introspection and mild visual distortions and enhancement, accompanied with mild intensification of colour perception; higher doses increase these symptoms and induce a powerful psychedelic state; higher doses still can induce a state similar to oral *DMT* activated by an MAOI (Hofmann et al. 1959; Ott 1993; pers. obs.). Potent agonist of 5-HT2a receptors, and to a lesser extent, 5-HT1a & 5-HT2b (McKenna et al. 1990). Weak MAOI in rat liver (McKenna et al. 1984b). Metabolite of *psilocybin*; rapidly absorbed from g.i. tract. Appears in blood plasma after 30 minutes. Most is excreted in the first 8hrs following consumption [c.25% excreted unchanged], with metabolites detected in urine even after 7 days. *Psilocin* is metabolised to 4-OH-indole-3-acetaldehyde and O-glucuronide; 4-OH-indole-3-acetaldehyde is then metabolised to 4-OH-indole-3-acetic acid and 4-OH-tryptophol. *Psilocin* oxidises to produce a blue pigment of unknown structure [see **Psilocybe** for discussion] (Hasler et al. 1997; Passie et al. 2002; Perkal 1981). Controlled substance.

Psilocybin $C_{12}H_{17}N_2O_4P$

[indocybin; psilocybine; psilocine O-phosphate; O-phosphoryl-4-OH-DMT; 3-(2-dimethylamino)ethyl-1H-indol-4-ol dihydrogen phosphate ester]



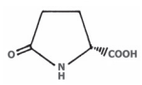
Crystals from boiling methanol or boiling water; mp. 185–195°C and 220–228°C, respectively; sol. in boiling water; moderately sol. in boiling methanol; slightly sol. in ethanol; practically insol. in chloroform, benzene.

Active from 2–4mg, psychedelic at 10–40mg; highest recorded human dose 120mg (Fisher 1965; Hofmann et al. 1959). Similar activity to *psilocin* – thought to be inactive until metabolised in the body by dephosphorylation to *psilocin* [4-OH-indoleacetic acid is also a metabolite from

this reaction in human plasma, and phosphoric acid is released]. This reaction does not seem to occur in alkaline [basic] solutions, but does in acidic and neutral solutions (Hasler et al. 1997; Horita & Weber 1961; Ott 1993; Perkal 1981). Agonist of 5-HT2a [mainly], 5-HT1a, 5-HT1d and 5-HT2c receptors. Reduces alpha and theta frequencies, and increases beta waves, in neocortex. Detectable in blood within 20-40 min. after consumption; only 50% of isotope-labelled *psilocybin* was absorbed after oral consumption; 3-10% is excreted unaltered. Given i.v., effects last only 15-30 minutes (Passie et al. 2002; Vollenweider et al. 1999). Small doses can improve visual acuity in humans (Fischer et al. 1992) and alleviate cluster headaches (Sewell et al. 2006). Weaker than *psilocin* as an MAOI in rat liver (McKenna et al. 1984b). Tolerance to the effects develops, but not as rapidly as with *mescaline*, requiring at least several days between exposures to return full response; cross-tolerance is also seen with *mescaline* and LSD (Appel & Freedman 1968). LD50 in mice [i.v.] – 285mg/kg; in rabbits [i.v.] – 12.5mg/kg (Budavari et al. ed. 1989). Best extracted from mushrooms by homogenisation with methanol [3ml per 100mg of dried mushrooms] for 2 min.; longer extraction times are apparently not needed (Perkal 1981). Later studies suggest that 75% methanol saturated with potassium nitrate is more effective than straight methanol (Wurst et al. 2002). Controlled substance.

Pyroglutamic acid $C_5H_7NO_3$

[pyroglutamate; glutamic acid lactam; α-aminoglutaric acid lactam; pidolic acid; glutimic acid; glutiminic acid; 5-oxoproline; 5-oxo-2-pyrrolidinecarboxylic acid; 2-pyrrolidone-5-carboxylic acid]

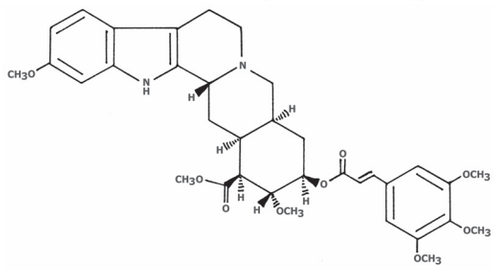


Crystals from water, mp. 156–157°C; or orthorhombic bisphenoidal crystals from alcohol and petroleum ether, mp. 162–163°C; sol. in water, alcohol, acetone. Easily prepared from L-*glutamic acid* by autoclaving with an equal weight of water at 135–140°C.

Present in large amounts in brain, blood and cerebrospinal fluid. Precursor to *glutamic acid*, catalysed by the enzyme 5-oxoprolinase. Improves memory, learning and attention, and has some anxiolytic effects (Moret & Briley 1988). Found in vegetables, fruits, grasses and molasses (Buckingham et al. ed. 1994). See *Neurochemistry*.

Rescinnamine $C_{35}H_{42}N_2O_9$

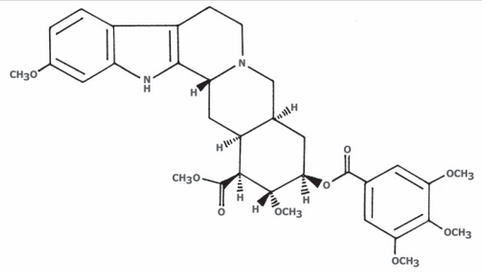
[reserpic acid O-(3,4,5-trimethoxycinnamoyl)methyl ester; sometimes called reserpinine incorrectly]



Fine needles from benzene; mp. 238–239°C [in vacuo]; practically insol. in water; moderately sol. in methanol, benzene, chloroform, and other organic solvents.

Antihypertensive, tranquilliser; similar pharmacology to *reserpine*, but less potent (Bruneton 1995; Buckingham et al. ed. 1994). Medicinal dose 0.5mg once or twice daily for 2 weeks, after which the dose is reduced to 0.25mg daily (Morton 1977).

Reserpine $C_{33}H_{40}N_2O_9$

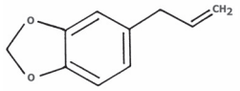


Long prisms from dilute acetone; mp. 262–266/284–285°C [dec. 264–265°C (277–277.5 in vacuo)]; very sparingly sol. in water; freely sol. in chloroform, methylene chloride, glacial acetic acid; sol. in benzene, ethyl acetate; slightly sol. in acetone, methanol, ethanol, ether, and in aqueous solns. of acetic and citric acids. Weak base. Upon standing most solns. acquire a yellow colour and pronounced fluorescence, especially after addition of acid or upon exposure to light.

Tranquilliser, antihypertensive (Buckingham et al. ed. 1994; Budavari et al. ed. 1989), sedative, hypnotic. Initially a brief sympathomimetic effect, followed by a slowly developing and prolonged fall in blood pressure, often with brachycardia and peripheral vasodilation. Depletes the brain of *serotonin* and catecholamines. Side effects of over-use may include depression, impotence in men, restlessness, nightmares and gastric ulceration. Overdose can cause death from respiratory depression. Can worsen asthma and bronchitis. Medicinal dose 0.05–2mg daily [orally or injected] (Beckman 1961; Bruneton 1995; Goodman & Gilman 1975; Morton 1977; Watt & Breyer-Brandwijk 1962). Given with an MAOI to animals, can cause central excitation and mydriasis similar to that induced by LSD (Squires 1978). In many Apocynaceous plants, particularly **Rauwolfia**; also in Tenduzia longifolia (Buckingham et al. ed. 1994).

Safrole $C_{10}H_{10}O_2$

[allylcatechol methylene ether; 3,4-methylene-dioxyallylbenzene; 5-(2-propenyl)-1,3-benzodioxole; 4-allyl-1,2-(methylenedioxy)benzene]

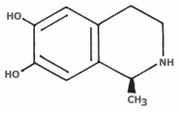


Colourless or slightly yellow liquid with **Sassafras** odour; bp. 231.5–234°C; insol. in water; very sol. in alcohol; miscible with chloroform, ether. Although sometimes spelled as 'safrol', this should not be confused with the drimane sesquiterpene also called safrol.

Psychoactive in animals, causing excitation followed by sedation (Oswald et al. 1971b); topical antiseptic, pediculicide, carminative. Intermediate in manufacture of perfume ingredients. Irritant, may be carcinogenic in very large doses or extended exposure (Ames et al. 1987; Buckingham et al. ed. 1994; Budavari et al. ed. 1989; Hall 1973; Segelman et al. 1976b). LD50 in rats [oral] – 1950mg/kg; in mice [oral] – 2350mg/kg (Budavari et al. ed. 1989). Non-amine precursor to MDA [3,4-methylenedioxy-*amphetamine*], which is active from 60-80mg, lasting 8-12hrs. MDA is euphoric, empathogenic, and a mild psychedelic stimulant (Shulgin & Shulgin 1991), and a controlled substance. The in vivo metabolism of *safrole* to MDA has not actually been demonstrated. Rats have been shown to metabolise it predominantly to 3-piperidyl-1-(3',4'-methylenedioxyphenyl)-1-propanone; guinea pigs have been shown to metabolise it predominantly to 3-N,N-dimethylamino-1-(3',4'-methylenedioxyphenyl)-1-propanone [these might also prove to be psychoactive]. Both compounds decompose to form 1-(3',4'-methylenedioxyphenyl)-3-propen-1-one (Oswald et al. 1971a).

Salsolinol $C_{10}H_{13}NO_2$

[1,2,3,4-tetrahydro-6,7-dihydroxy-1-methylisoquinoline; 1,2,3,4-tetrahydro-1-methyl-6,7-isoquinolinediol]



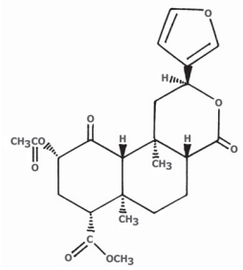
Crystals from ethanol/ether; mp. 174–175°C.

Occurs in humans as a mix of the (S)- and (R)-isomers; acts as an endogenous 'false neurotransmitter', formed from *dopamine* and acetaldehyde. Levels increase in humans when alcohol is consumed, though it

is present endogenously without alcohol intake (Buckingham et al. ed. 1994; Collins 1983; Deitrich & Erwin 1980; Haber et al. 1999). Inhibits MAO-A [the R-stereoisomer being c.10x as potent as the S-stereoisomer] (Bembenek et al. 1990; Feenstra et al. 1983); inhibits tyrosine hydroxylase; potent inhibitor of *dopamine*-uptake in rat brain; COMT inhibitor (Buckingham et al. ed. 1994; Deitrich & Erwin 1980); inhibits binding to mu opiate-receptors; weakly inhibits binding of leu-*enkephalin* to delta opiate-receptors (Airaksinen et al. 1984); inhibits release of pituitary *adrenocorticotropin* and β-*endorphin*; inhibits formation of cAMP; binds strongly to D2 and D3 *dopamine* receptors (Melziga et al. 2000). See *Neurochemistry*.

Salvinorin A $C_{23}H_{28}O_8$

[divinorin A; 15,16-epoxy-2-hydroxyl-1-oxo-13(16),14-clerodadien-17,12-olid-18-oic acid-2-Ac, methyl ester]

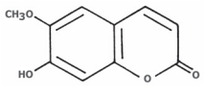


Crystals; mp. 242–244 °C; sol. in methanol, chloroform; miscible in corn oil/Tween-80/water; insol. in water.

Highly psychedelic; strongly active by smoking [preferably vapourising] at 200–1000mcg; sublingually at up to 2mg or more. When smoked, effects are +- instantaneous, with no noticeable transition period; the user usually experiences sensations of incredible force and motion, appearance of 2-dimensional membranes or surfaces, overlapping realities, loss of body-identity, hilarity [or terror], vivid time-travel to places from one's past, becoming static objects, and extremely bizarre and vivid visual hallucinations, often plant-based in nature. Main effects last several minutes, and return to 'baseline' occurs over several hours to several days, often with a pleasant afterglow and sense of awe-inspiring wonder. Sublingual effects are slower in onset and effect, and usually more manageable, lasting in the main about 20 minutes (Pendell 1995; Siebert 1994; Valdés 1994; pers. comms.; pers. obs.). Approach with extreme respect! Did not bind significantly to known receptor sites in preliminary tests (Siebert 1994), but a recent study found *salvinorin A* to be a potent selective agonist of kappa opioid-receptors (Roth et al. 2002). The main metabolite is probably salvinorin B (Schmidt et al. 2005). Recently made illegal in Australia [schedule 9 poison along with heroin, *cocaine*, etc.]; still legal almost everywhere else at time of printing [see **Salvia** for specifics], though it is under scutiny in the US.

Scopoletin $C_{10}H_8O_4$

[escopoletin; buxuletin; 7-hydroxy-6-methoxy-2H-1-benzopyran-2-one; 7-hydroxy-6-methoxy-coumarin; aesculetin 6-methyl ether; chrysatropic acid; gelseminic acid; β-methylaesculetin]

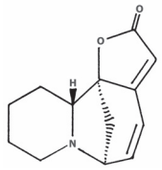


Needles or prisms from chloroform, ethanol or acetic acid; mp. 204°C; slightly sol. in water or cold alcohol; sol. in hot alcohol or hot glacial acetic acid; moderately sol. in chloroform; practically insol. in benzene. The alcoholic solution has a blue fluorescence.

Human psychopharmacology unknown. MAOI (Yun et al. 2001); hypotensive neuromuscular-blocker (Ojewole & Adesina 1983), hypnotic in animals in very large doses (MacRae & Towers 1984b). In many plants, including Cyphomandra betacea (Kala 1958).

Securinine $C_{13}H_{15}NO_2$

[securinan-11-one]

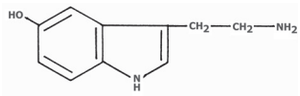


Yellow crystals from alcohol; mp. 142–143°C.

CNS stimulant with *strychnine*-like activity, but less than 10x as potent; affects autonomic nervous system, and acts primarily on spinal cord, enhancing reflex activity. *GABA*-a receptor agonist, inhibits cholinesterase, causes respiratory stimulation, hypotension and increased muscle tone. Toxic effects include tremors and rigid contractions, and death can result from orthotonic convulsions. It is poorly absorbed through the GI-tract; c.20% of an administered dose is absorbed into body fluids, where it is quickly broken down. LD50 in rats [oral] – >800mg/kg; in mice [oral] – 270mg/kg (Buckingham et al. ed. 1994; Huang 1993; Hui-Yung 1974).

Serotonin $C_{10}H_{12}N_2O$

[5-hydroxy-tryptamine; 5-HT; hippophaine; thrombocytin; thrombotonin; enteramine; anthemovister; 3-(2-aminoethyl)-1H-indol-5-ol; 3-(2-aminoethyl)-5-hydroxyindole]

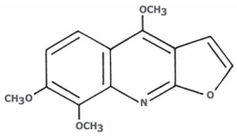


Small whitish crystals; mp. 167-168°C [HCl]; sol. in water [more so at greater temps.], glacial acetic acid; slightly sol. in methanol, 95% ethanol; insol. in absolute ethanol, acetone, chloroform, benzene. Very stable at low pH.

Behavioural sedative, causes 'behavioural disturbance' in rats; decreases anxiety and aggression, inhibits arousal and orgasm. Vasoconstrictor, smooth muscle contractant, antidiuretic, reduces gastric secretions. Involved in allergic reactions and pain [eg. see **Urtica** for an exogenously-produced example], as well as migraine and emesis. Increases *adrenocorticotropin* secretion. Human neurotransmitter biosynthesised from *5-hydroxytryptophan* or *tryptamine*; does not cross blood-brain barrier (Crenshaw & Goldberg 1996; Curtis & Davis 1961; Garattini & Valzelli 1965; Gessner et al. 1961; Kruk & Pycock 1983; Mantegazzini 1966; Sternbach 1991; Young 1983). For discussion on '*serotonin* syndrome' see *Influencing Endogenous Chemistry* and Sternbach (1991). See *Neurochemistry*.

Skimmianine $C_{14}H_{13}NO_4$

[β-fagarine; chloroxynonine; pentaphylline; 7,8-dimethoxydictamnine; 4,7,8-trimethoxyfuro[2,3-b]quinoline]

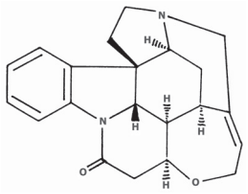


Pyramids or octahedral rods from alcohol; mp. 176-178°C; sol. in alcohol, chloroform; slightly sol. in ether, amyl alcohol, carbon disulfide; practically insol. in water and petroleum ether. Neutral pH.

Analgesic, anticonvulsant, antipyretic, potentiates the effects of barbiturates, CNS depressant (Harborne & Baxter ed. 1993); behavioural sedative in animals, and showed mild anti-*methamphetamine* activity (Cheng 1986). Claimed to have some *ephedrine*-like pharmacological activity (Buckingham et al. ed. 1994). Ligand of 5-HT2 receptors (Cheng et al. 1994). Has been found in a variety of Rutaceae, including Skimmia japonica (Buckingham et al. ed. 1994), Fagara spp., Glycosmis pentaphylla and Ruta graveolens (Budavari et al. ed. 1989).

Strychnine $C_{21}H_{22}N_2O_2$

[strychnidin-10-one]

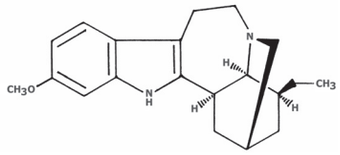


Very bitter orthorhombic sphenoidal prisms from alcohol; mp. 268–290°C [depending on speed of heating]; bp. 270°C; sol. in glycerol, amyl alcohol, methanol, toluene, benzene, ethanol; moderately sol. in boiling water; highly sol. in chloroform, boiling alcohol; very slightly sol. in ether, petroleum ether. Readily forms crystalline chloromethochloride artefacts when chloroform or methylene chloride is used in isolation.

CNS excitant, powerful convulsant (Goodman & Gilman 1975). Antagonises *glycine* at post-synaptic sites (Holmstedt 1995); antagonises *taurine* activity (Kruk & Pycock 1983); cholinesterase inhibitor (Orgell 1963a). An early sign of poisoning is stiffness of face and neck muscles, followed by increased reflex excitability which can lead to convulsions from over-response to sensory stimuli. Death can result from respiratory interference. Treatment should involve maintaining a clear airway, avoiding sensory stimulation, and administration of a muscle relaxant [such as *diazepam*, 10mg i.v.]. Fatal in humans 30-100mg; children may experience serious toxicity from 15mg (Goodman & Gilman 1975). Small doses sometimes used as a tonic. Sometimes used as a rat poison. LD50 in mice – 2mg/kg [oral] (Buckingham et al. ed. 1994).

Tabernanthine $C_{20}H_{26}N_2O$

[11-methoxy-ibogamine; 13-methoxy-ibogamine]



Needles or shiny leaflets from ethanol; mp. 209-212/213.5-215°C [subl. 160°C]; sol. in alcohol, benzene, ether, chloroform; practically insol. in water.

CNS-stimulant 17x less potent than *ibogaine* (Bert et al. 1988); hypotensive, brachycardiac (Buckingham et al. ed. 1994). Induces low frequency [4–6 Hz] rhythmic activity in the neocortex in rats. Binds at delta and kappa opiate-receptors; NMDA-receptor antagonist; BZ-receptor antagonist; increases turnover and synthesis of *dopamine* and *norepinephrine* in brain cortex. Induces fine-tremors; tremorgenic at 1.4mg/kg [s.c.] in mice. LD50 in mice [i.v.] – 38mg/kg (Deecher et al. 1992; Layer et al. 1996; Prioux-Guyonneau et al. 1984; Trouvin et al. 1987; Van Beek et al. 1984; Zetler et al. 1972).

Taurine $C_2H_7NO_3S$

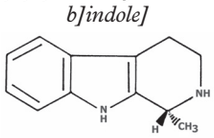
[2-aminoethanesulfuric acid; aminoethylsulfonic acid; ethylaminesulfonic acid]

Monoclinic prismatic rods; mp. 328°C [dec. 320-325°C]; sol. in water; insol. in alcohol. Emits toxic fumes on heating.

Depresses neuronal excitability, antiepileptic, antiarrhythmic (Kruk & Pycock 1983). Metabolic regulator; intermediate in metabolism of cysteine. Occurs in free form in animal tissues, bacteria, red algae, and some higher plants [eg. leguminous seedlings] (Buckingham et al. ed. 1994). See *Neurochemistry*.

Tetrahydroharman $C_{12}H_{14}N_2$

[eleagnine; calligonine; 1-methyl-THβC; 1,2,3,4-tetrahydro-1-methyl-β-carboline; 1,2,3,9-tetrahydro-1-methyl-1H-pyrido[3,4-b]indole]

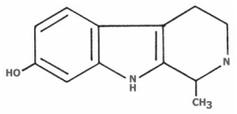


Mp. 144-148°C; (+-)-form [in **Leptactinia** densiflora] mp. 178-180°C; sol. in ethanol.

MAOI less potent than *harman* in mouse brain (Buckholtz & Boggan 1977); inhibits AChE, and non-competitively inhibits muscarinic *acetylcholine*-receptor binding, in rat brain, though less potent in this regard than *harman* or *norharman* (Skup et al. 1983); weakly inhibits binding of leu-*enkephalin* to delta opiate-receptors (Airaksinen et al. 1984). CNS depressant in rats; caused paralysis in higher doses (Ho 1977).

Tetrahydroharmol $C_{12}H_{14}N_2O$

[1,2,3,4-tetrahydro-7-hydroxy-1-methyl-β-carboline; 2,3,4,9-tetrahydro-1-methyl-1H-pyrido[3,4-b]indol-7-ol]

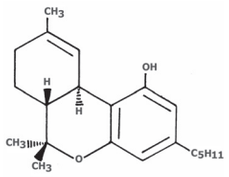


Mp. 254-255°C.

Normal component of human urine (Shulgin & Shulgin 1997). MAOI equipotent to *harmalol* in vitro in rat brain (Buckholtz & Boggan 1977). See *Neurochemistry*.

THC $C_{21}H_{30}O_2$

[Δ-1- or Δ-9-tetrahydrocannabinol; 6a,7,8,10a-tetrahydro-6,6,9-trimethyl-3-pentyl-6H-dibenzo[b,d]pyran-1-ol; marinol™; dronabinol]

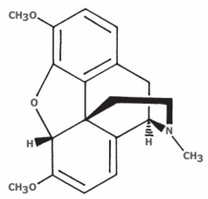


Resinous oil; bp. 200°C in vacuum; sol. in oils, fats, ethanol, methanol, butane, acetone; insol. in water. Oxidised to *cannabinol* in presence of air.

Psychoactive at 50-200μg/kg orally, 25-50μg/kg smoked, though partially destroyed in the burning of smoking (Mechoulam 1970); euphoric, mild psychedelic. Anti-asthmatic, analgesic, antiglaucomic, antihypertensive, anti-emetic (Cohen & Stillman ed. 1976; Grinspoon & Bakalar 1995; Noyes et al. 1975). Cannabinoid-receptor agonist (Piomelli et al. 2000). Has been found variously to either slightly suppress, or increase, MAO activity; inhibits amine uptake and *acetylcholine* release, as well as depressing presynaptic cholinergic neurotransmission. May suppress symptoms of *morphine* withdrawal (Coper 1982). Potent antioxidant (Hampson et al. 1998). Protects against ischemic neuronal damage in the striatum; this effect is only noted in the hippocampus in high doses (Louw et al. 2000). Ameliorates some symptoms of Multiple Sclerosis in experimental studies (Baker 2000; Di Marzo et al. 2000). Shows potential in destroying malignant gliomas in rat studies (Galve-Roperh et al. 2000; Piomelli 2000). Smoked *THC* [a single 1g cigarette laced with 1% Δ-9-*THC*] has been shown to cause massive increases in serum *melatonin* levels [greatest effect after 2hrs], except in one person who had high baseline *melatonin* levels, for whom the laced cigarette led to a reduction in serum *melatonin* (Lissori et al. 1986). Stimulates release of dynorphins A and B, as well as leu-*enkephalin*, in spinal cord (Houser et al. 2000; Welch & Eads 1999). In female rats, *THC*-mediated sexual receptivity [which is mediated through the CB1-receptor] has been shown to be modulated, at least partly, by *dopamine* D1 receptors and progesterone receptors (Mani et al. 2001). Controlled substance.

Thebaine $C_{19}H_{21}NO_3$

[paramorphine; codeinone methylenol ether; 6,7,8,14-tetradehydro-4,5-epoxy-3,6-dimethoxy-17-methylmorphinan]



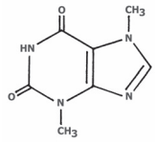
Orthorhombic, rectangular plates from ethanol; needles by sublimation; also obtained in cubes and prisms; mp. 193°C; sol. in ether; moder-

ately sol. in water; freely sol. in chloroform, benzene, pyridine, hot alcohol; practically insol. in petroleum ether.

Stronger narcotic but weaker analgesic than *morphine*; more toxic than *morphine*, can produce *strychnine*-like symptoms in higher doses. Increases the effects of *caffeine*. Causes *histamine* release from tissues; cholinesterase inhibitor. LD50 in mice [i.p.] – 20mg/kg (Buckingham et al. ed. 1994; Budavari et al. ed. 1989; Preininger 1975). Controlled substance. A synthetic *thebaine* transformation-product, named Cl 110,393, has LSD-like effects [see *mescaline* and *psilocin*, which have very similar effects to LSD in many regards] lasting more than 21hrs [in doses of 1mcg/kg (i.m.) and above] (Angrist & Gershon 1973).

Theobromine $C_7H_8N_4O_2$

[diurobromine; santheose; thesal; 3,7-dihydro-3,7-dimethyl-1H-purine-2,6-dione; 3,7-dimethylxanthine]

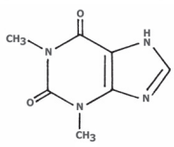


Monoclinic needles from water; mp. 351-357°C; sublimes 290-295°C; sol. in water, alcohol, fixed alkali hydroxides, concentrated acids; very sol. in boiling water; moderately sol. in ammonia; almost insol. in benzene, ether, chloroform. Forms salts which are dec. by water, and compounds with bases which are more stable.

Very weak CNS and respiratory stimulant; bronchodilator, diuretic, cardiac stimulant, smooth muscle relaxant, arterial dilator (Buckingham et al. ed. 1994; Goodman & Gilman 1975). About 1/10 the potency of *caffeine* or *theophylline* as a stimulant (Gilbert 1980). Highly toxic orally (Buckingham et al. ed. 1994), presumably only in very large doses (pers. obs.). *Adenosine* receptor antagonist, weaker than *caffeine* or *theophylline* (Snyder & Sklar 1984); weak phosphodiesterase inhibitor, increasing cAMP levels and potentiating effects of β-adrenergic stimulation, though at levels much higher than those achieved naturally (Goodman & Gilman 1975; Kruk & Pycock 1983).

Theophylline $C_7H_8N_4O_2$

[1,3-dimethylxanthine; theocin; 3,7-dihydro-1,3-dimethyl-1H-purine-2,6-dione]

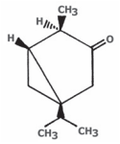


Monohydrate, thin monoclinic tablets from water, bitter; mp. 264-268/270-274°C; very sol. in water, alcohol, chloroform; sol. in alkali hydroxides, ammonia, dilute HCl; sparingly sol. in ether.

Weak CNS and respiratory stimulant (Goodman & Gilman 1975), bronchodilator (Budavari et al. ed. 1989); diuretic, cardiac stimulant and smooth muscle relaxant more potent than *caffeine* or *theobromine* (Buckingham et al. ed. 1994; Goodman & Gilman 1975). Highly toxic orally (Buckingham et al. ed. 1994; Goodman & Gilman 1975), can elicit convulsions at 50% higher than the therapeutic dose for asthma (Snyder & Sklar 1984). This might instead refer to known occasional toxicity of aminophylline [*theophylline* ethylenediamine], the form of the drug most commonly used in medicine (pers. obs.). *Adenosine*-receptor antagonist slightly more potent in vitro than *caffeine* (Biaggioni et al. 1991; Snyder & Sklar 1984); weak phosphodiesterase inhibitor, increasing cAMP levels and potentiating effects of β-adrenergic stimulation, though at levels much higher than those achieved naturally (Biaggioni et al. 1991; Goodman & Gilman 1975; Kruk & Pycock 1983).

Thujone $C_{10}H_{16}O$

[(-)-α-thujone:- l-thujone; (-)-3-isothujone; (1S,4R,5R)-3-thujanone] [(+)-α-thujone:- d-thujone; (+)-isothujone; (+)-3-thujone; (1S,4R,5R)-3-thujanone]



Equilibrium mixture contains 33% α- (shown) and 67% β-thujone. Colourless or almost colourless liquid; bp. 78-83.8°C [α], 85.7–86.2/201–202°C [β]; practically insol. in water; sol. in alcohol and many other organic solvents.

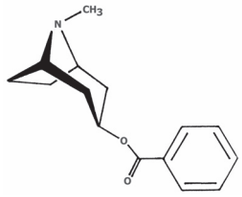
Psychotropic, anthelmintic, uterine-stimulant, antagonises narcotic-poisoning (Albert-Puleo 1978). Suggested to act on similar receptor systems to *THC*, based on some similarities in molecular structure, although this was not actually demonstrated (Del Castillo et al. 1975). α-*Thujone* is also analgesic, and modulates *GABA*-a receptors; β-*thujone* is less toxic. Metabolised by cytochrome P450 (Hölld et al. 2000). Ingestion may cause convulsions (Hall 1973). LD50 of the equilibrium mixture in mice [s.c.] – 134.2mg/kg; LD50 of α-*thujone* in mice [s.c.] – 87.5mg/kg; LD50 of β-*thujone* in mice [s.c.] – 442.2mg/kg (Budavari et al. ed. 1989).

Tribulin

Originally the name given to an endogenous MAOI detected in human urine [also inhibits binding to BZ-receptors, shows anxiogenic activity], now known to consist of at least 4 constituents, the makeup differing in different body tissues. These constituents of *tribulin* include *isatin*, 4-OH-phenylethanol, 4-OH-phenylacetate, ethyl indole-3-acetate [and/or methyl 3-indole-propionate] and methyl indole-3-acetate [all inhibiting MAO-A]. Women generally have higher levels of endogenous *tribulin* than men (Glover 1998; Glover et al. 1987; Hucklebridge et al. 1998b; Medvedev 1996, 1999; Medvedev et al. 1995a, 1995b). See *Neurochemistry*, *Influencing Endogenous Chemistry*.

Tropacocaine $C_{15}H_{19}NO_2$

[O-benzoyl-exo-3-hydroxytropane; O-benzoyl-exo-3-tropanol]

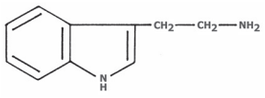


Plates or tablets; mp. 49°C; distills in vacuo without dec.; freely sol. in alcohol, ether, chloroform, benzene, petroleum ether, dilute acids; slightly sol. in water.

Said to be 'poisonous' (Buckingham et al. ed. 1994; Harborne & Baxter ed. 1993). Human pharmacology poorly known; causes local anaesthesia more rapidly than *cocaine*, though is scarcely mydriatic; otherwise "it resembles *cocaine* generally in action" (Henry 1939). Inhibits *choline* and *norepinephrine* uptake, and *acetylcholine* synthesis (Meyer et al. 1990). LD50 in rats [i.v.] – 15-20mg/kg (Budavari et al. ed. 1989).

Tryptamine $C_{10}H_{12}N_2$

[1H-indole-3-ethanamine; 3-(2-aminoethyl)indole; 2-(3-indolyl)ethylamine]

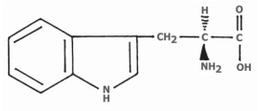


Needles from petroleum ether; mp. 118°C; bp. 137°C; sol. in ethanol, acetone; practically insol. in water, ether, benzene, chloroform.

Psychotropic. Increases blood pressure, causes mydriasis, nausea, bodily sedation, dizziness, sweating, mild increase of awareness, and mild, brief visual and auditory changes [infused i.v. over several minutes, 23-277mg] (Martin & Sloan 1970, 1986). Claimed by some to be mildly psychoactive by smoking (Shulgin & Shulgin 1997). Excitant in mice and cats [given i.v.] (Squires 1978). Can induce catatonia, possibly mediated by an indirect anticholinergic action, and antagonised by *serotonin*. Endogenous mammalian neurochemical, biological prescursor to *N-methyltryptamine*, *DMT* (Axelrod 1961; Barker et al. 1981; Corbett et al. 1978; Hanson 1966; Martin & Sloan 1986; Saavedra & Axelrod 1973; Tanimukai et al. 1970; Van Andel & Ernst 1961; Webster 1989). Weak MAOI in rat liver (McKenna et al. 1984b). In animals, it only appears to enter the brain in large doses (Martin & Sloan 1970), though it is apparently lipophilic enough to cross the blood-brain barrier (Young 1983). In any case, it is inactive orally (Shulgin & Shulgin 1997), presumably due to its rapid degradation by MAO. Co-administration with an MAOI, or instead ingestion of *tryptophan* with MAOI, may allow for its passage into the brain where it will most likely be metabolised to form other indoles (pers. obs.). See *Neurochemistry*.

Tryptophan $C_{11}H_{12}N_2O_2$

[2-amino-3-(3-indolyl)propanoic acid]

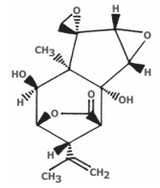


Leaflets or plates from dilute alcohol; mp. 252/278/289°C [dec. 289°C]; sol. in water, hot alcohol, alkali hydroxides; insol. in chloroform. Enzymatic hydrolysis product of most plant and animal proteins.

Antidepressant [4-6g a day], sedative; most effective in people with a dietary *tryptophan* deficiency. Further study is needed to determine its range of efficacy. Biological precursor to *tryptamine*, *serotonin* [via *5-hydroxytryptophan*] and *melatonin*, as well as other indoles. Best taken with 1–1.5g a day of nicotinamide [a form of vitamin B3] to enhance conversion to *serotonin*; nicotinamide inhibits the liver enzyme *tryptophan* pyrrolase, which would normally process much of the *tryptophan* ingested to vitamin B3. Increases slow-wave sleep. Can cause mild perceptual changes and heavy sedation [with some euphoria] in large doses [5-8g orally; one study used 30-90mg/kg (oral)], or in smaller doses with an MAOI and/or *methionine*. Some 'schizophrenics' may be more sensitive to these latter combinations. Side effects of large doses [c.9g and above] may include dry mouth, nausea, vomiting, headache, 'lightheadedness', blurred vision, tremors, diarrhoea and possibly bladder carcinoma [an indirect action observed in animal studies]; given with MAOI, side effects may include 'intoxication', tremor, hyperreflexia, flushing, low blood pressure when standing upright and nystagmus. As mentioned above, larger doses can prove counter-productive, as high levels induce activity of the enzyme *phenethylamine* pyrrolase, forming kynurenine [which reduces brain *serotonin* levels] as a product of vitamin B3 synthesis (Harper 1973; Kety 1961; Kruk & Pycock 1983; Mandell et al. 1969; Maurizi 1990; Shaw et al. 2002; Smith & Prockop 1962; Upfal 1995; Van Praag 1981; Wurtman 1987a). Increases *tribulin* levels in rat brain (Bhattacharya et al. 1991a). Amino acid present in small amounts in foods. Restricted substance. See *Neurochemistry*, *Influencing Endogenous Chemistry*.

Tutin $C_{15}H_{18}O_6$

[coriarin; 2-hydroxy-coriamyrtin]

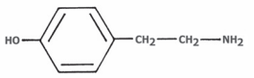


White, odourless crystals from ethanol or water; mp. 204-205/209-213°C ; sol. in water, alcohol, ether.

Poisonous (Buckingham et al. ed. 1994), CNS excitant, stimulates respiratory, vasomotor and cardioinhibitory brain centres (Harborne & Baxter ed. 1993). Causes giddiness, stupor, delirium, convulsions and coma (Budavari et al. ed. 1989). Reduces inhibitory action of *glycine*, has some *GABA*-antagonist activity (Curtis et al. 1973). LD50 in female mice – 3mg/kg [i.p.] (Budavari et al. 1989). Also found in Toxicodendron capense (Buckingham et al. ed. 1994).

Tyramine $C_8H_{11}NO$

[p-tyramine; 4-hydroxyphenethylamine; tyrosamine; 4-(2-aminoethyl)phenol; 2-(p-hydroxyphenyl)ethylamine]

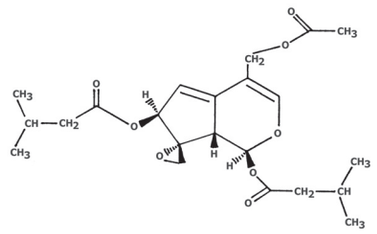


Crystals from benzene or alcohol; mp. 161/164-165°C; bp. 166/205-207°C; alkaline reaction; sol. in water, boiling alcohol; sparingly sol. in benzene, xylene.

Adrenergic (Budavari et al. ed. 1989); can cause release of brain *norepinephrine* and *dopamine* (Saavedra 1989); blocks *norepinephrine* and *dopamine* re-uptake, increases *norepinephrine* release (Kruk & Pycock 1983). Has indirect *norepinephrine*-like effects, though slower in onset and less marked; does not appear to have behavioural effects of its own (Webster 1989). Found in putrefied animal tissue, fermented foods, ripe cheese; should not be combined with an MAOI (Budavari et al. ed. 1989; Mashford et al. 1993). Endogenous mammalian neurochemical formed from tyrosine, *phenylalanine*, *l-DOPA*, *dopamine* and/or *phenethylamine*; prescursor to *dopamine*, octopamine (Boulton & Juorio 1982; Webster 1989). Also exists in other isomeric forms – o-*tyramine* [2-OH-*phenethylamine*] and m-*tyramine*. The former has been found in mammalian urine, but only in very low concentrations in brain; it has *amphetamine*-like effects (Boulton & Juorio 1982). Does not cross the blood-brain barrier (Marley & Stephenson 1972). See *Neurochemistry*. Also found in Aster linariifolius, Chlorophytum capense, Colocasia antiquorum, Cordyline terminalis, Crinum sp., Jacaranda acutifolia, Juglans nigra, Liriope spicata, Mariscus jamaicensis, Nandina domestica, Pyrostegia ignea, Sambucus canadensis and Schinus terebinthifolius (Wheaton & Stewart 1970).

Valtrate $C_{22}H_{30}O_6$

[valtratum; valepotriate; valepotriatum; baldrisedon; halazuchrome B]



Oil; insol. in water.

Sedative (Buckingham et al. ed. 1994), tranquilliser, improves coordination, antagonises alcohol-induced hypotension (Harborne & Baxter ed. 1993), spasmolytic, anticonvulsant, increases *GABA* levels. Larger doses can be toxic (Hobbs 1993).

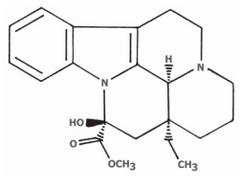
Vasopressin $C_{46}H_{65}N_{15}O_{12}S_2$

Human vasopressin is 8-L-arginine vasopressin [the formula given above]

Mammalian pituitary peptide hormone (Buckingham et al. ed. 1994; Budavari et al. ed. 1989). Improves attention, concentration and memory, modifies sleeping patterns, alters pain response, mediates some aspects of sexual arousal [dependent on presence of testosterone]. Has some *adrenocortocotropin*-releasing activity; potentiates cholinergic activity, and *glutamic acid* activity in some areas of brain; modulates α1-adrenergic activity. Stimulates thirst (Crenshaw & Goldberg 1996; Dean & Morgenthaler 1990; Kovacs & De Wied 1994; Kruk & Pycock 1983). Vasopressor, antidiuretic, haemostatic, reduces fever (Budavari et al. ed. 1989). Rapidly absorbed through nasal mucosa (Dean & Morgenthaler 1990). See *Neurochemistry*.

Vincamine $C_{21}H_{26}N_2O_3$

[vincamarine; minorine; perivincamine; methyl-14,15-dihydro-14-hydroxy-eburnamenine-14-carboxylate]

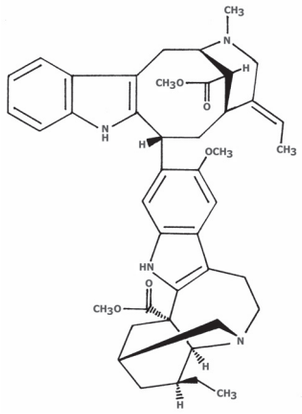


Occurs naturally as the D-form; yellow crystals from acetone or methanol; mp. 190-220/232-233[dec.]/274°C [dec.].

Antihypertensive (Buckingham et al. ed. 1994), cardiotonic, nöotropic. Induces low frequency [4-6Hz] rhythmic activity in the neocortex in rats; decreases alpha- and increases delta- and theta-wave activity. Sedative, depletes catecholamines. Causes cerebral vasodilation [increasing cerebral blood flow], and a biphasic fall in blood pressure. May stimulate neuronal metabolism, increasing utilisation of glucose and stimulating carbon dioxide production. Can improve memory, mood and concentration. Has a protective action in the brain; may cause enhanced cellular respiration. Oral therapeutic dose 30mg, twice daily (Bisset 1985a; Bruneton 1995; Dean & Morgenthaler 1990; Van Beek et al. 1984). LD50 in mice – 75mg/kg [i.v.]; >1000mg/kg [s.c.]; 1000mg/kg [oral] (Budavari et al. ed. 1989).

Voacamine $C_{43}H_{52}N_4O_5$

[voacanginine; 12-methoxy-13-[(3α)-17-methoxy-17-oxovobasan-3-yl]-ibogamine-18-carboxylic acid methyl ester]

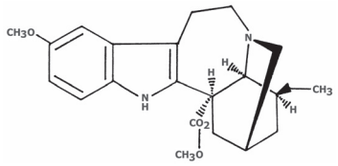


Prisms from acetone and methanol; mp. 224°C [dec. 223°C]; sol. in chloroform, acetone; slightly sol. in alcohol.

CNS stimulant or depressant 4.6x less potent than *ibogaine* (Bert et al. 1988); mild analgesic; cardiotonic of low toxicity; causes smooth-muscle contraction. In higher doses, causes hypertension due to peripheral vasoconstriction. LD50 – 360mg/kg [route of administration or species administered to not noted] (Bisset 1985a; Van Beek et al. 1984). Toxic to some cancers; some antibacterial action (Buckingham et al. ed. 1994).

Voacangine $C_{22}H_{28}N_2O_3$

[carbomethoxyibogaine; 12-methoxyibogamine-18-carboxylic acid methyl ether]

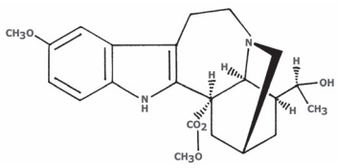


Prismatic needles from ethanol; mp. 136-138°C; sublimes 135°C; freely sol. in acetone, chloroform; slightly sol. in alcohol.

CNS stimulant 23x less potent than *ibogaine* (Bert et al. 1988); analgesic, hypothermic, surface anaesthetic, anticonvulsant, hypotensive; high doses cause convulsions, brachycardia and asphyxia; may cause some degree of catalepsy. Has some cytotoxic activity (Bisset 1985a; Buckingham et al. ed. 1994; Okuyama et al. 1992). LD50 in mice [i.v.] – 54mg/kg (Van Beek et al. 1984).

Voacristine $C_{22}H_{28}N_2O_4$

[voacangarine; 19-hydroxy-voacangine; 20-hydroxy-voacangine]

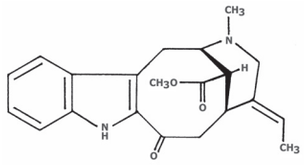


Crystals; mp. 112-114°C [dimorphous mp. 163-165°C].

CNS stimulant; hypotensive; can cause brachycardia. Weak cytotoxic activity against P-338 leukaemia cells. LD50 in mice – 77mg/kg [route of administration not noted] (Bisset 1985a; Buckingham et al. ed. 1994; Van Beek et al. 1984).

Vobasine $C_{21}H_{24}N_2O_3$

[N^4-methyl-perivine; methyl 3-oxovobasan-17-oate]

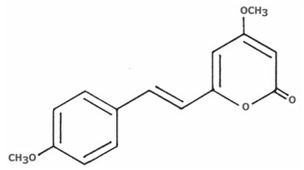


Crystals; mp. 111-113°C; sol. in ethyl acetate, acetone, chloroform, dichloromethane, methanol.

CNS stimulant [or depressant] 4.6x less potent than *ibogaine* (Bert et al. 1988), mild antipyretic and analgesic. Causes central and respiratory depression in large doses. LD50 in mice [i.v.] – 58mg/kg; however, cats have died from 10mg/kg [i.v.] (Bisset 1985a; Buckingham et al. ed. 1994; Van Beek et al. 1984).

Yangonin $C_{15}H_{14}O_4$

[4-methoxy-6-[2-(4-methoxyphenyl)ethenyl]-2H-pyran-2-one; 4-methoxy-6-(4-methoxystyryl)-α-pyrone]

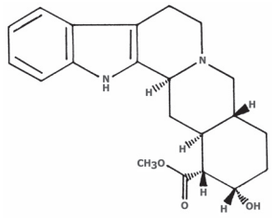


Greenish yellow crystals with blue fluorescence from methanol; mp. 153-157°C; practically insol. in water; sol. in hot alcohol, glacial acetic acid, ethyl acetate, acetone; slightly sol. in benzene, ether.

Muscle relaxant, anticonvulsant, sedative; strongly synergises with other 'kava-lactones' [see **Piper 2**] (Keller & Klohs 1963; Klohs 1967; Meyer 1967); MAO-B inhibitor in human platelets, slightly less potent than *methysticin* in this regard (Uebelhack et al. 1998). Nor-*yangonin* is found in Anaphalis adnata (Buckingham et al. ed. 1994).

Yohimbine $C_{21}H_{26}N_2O_3$

[yohimvetol; quebrachine; hydroergotocin; corynine; aphrodine; methyl(16-α,17-α)-17-OH-yohimban-16-carboxylate]



Orthorhombic needles from dilute ethanol; mp. 234-237/241°C; sparingly sol. in water; sol. in alcohol, chloroform, hot benzene; moderately sol. in ether.

Causes CNS excitation, increased blood pressure, heart rate and motor activity, sweating, nausea, local anaesthesia [similarly potent in this regard to *cocaine*] and mydriasis. Blockades α-2-adrenergic- and 5-HT2-receptors, and increases *serotonin* levels; releases stored *epinephrine* and *vasopressin*; increases *oxytocin*, *phenethylamine*, substance P, VIP, prolactin, cortisol and *acetylcholine* levels; decreases α-2 adrenergic, *GABA*, opioid and progesterone activity; inhibits plasma cholinesterase; increases *tribulin* levels in rat brain. Male aphrodisiac, though there is suppression of sexual activity at higher doses. Antidiuretic, antidepressant. Active around 15mg. Higher doses can cause nausea, arrhythmia, tremor, headache, dizziness, paraesthesia and anxiety. Has been used to treat angina pectoris and arteriosclerosis (Bhattacharya et al. 1991a; Bisset 1985a; Bruneton 1995; Buckingham et al. ed. 1994; Budavari et al. ed. 1989; Crenshaw & Goldberg 1996; Orgell 1963a). Should not be combined with tricyclic antidepressants (Fugh-Berman 2000). In combination with corynantheine, it has been sold as a *cocaine* substitute ['yocaine'] (Siegel 1980). Also found in Ladenbergia hexandra bark [traces] (Holker et al. 1964), Diplorhynchus spp., Lochnera spp., Pouteria spp. and Hunteria spp. (Meulen & Kerk 1964).

GLOSSARY

abortifacient — a substance used to procure abortion; or, referring to the property of causing abortion [ie. 'acting as an abortifacient']
AChEI — acetylcholinesterase inhibitor
achene — dry, one-seeded fruit which does not open [dehisce], formed from a superior mono-carpellate ovary
acidosis — medical condition involving high acidity in body fluids and tissues
acuminate — gradually tapering to a point
adaptogen — an agent that helps the body adapt to stress and novel situations
addiction — state of dependence related to habitual use of a substance or activity; usually correlated to physical dependence, wherin withdrawal symptoms are noted when the preferred substance or activity is not available
adrenergic — of or pertaining to neurons associated with ***epinephrine*** [adrenaline], or of an agent mimicking or promoting its effects; this relation also applies to the term ***noradrenergic***, with ***norepinephrine***, for example
adrenolytic — inhibits activity of ***epinephrine*** and/or adrenergic neurons
aghori — ascetic followers of Shiva, who believe that distinctions between opposites [such as concepts of 'good' and 'bad'] are illusory, and thus may sometimes be observed performing unusual acts outside the usual realms of social acceptability, such as performing rituals with human corpses, including eating the flesh
amenorrhoea — abnormal absence or stopping of menstrual periods
anaesthetic — any substance or procedure which reduces or abolishes sensation; general anaesthetics affect the whole body and produce unconsciousness; local anaesthetics only affect the region to which they are applied, and those closely surrounding it
analeptic — a CNS stimulant used to restore consciousness to a comatose person, or someone who has fainted
analgesic — any substance or procedure which relieves pain
anaphrodisiac — something which decreases sexual desire and/or ability
anodyne — something which soothes and/or eases pain
anthelmintic — eliminates intestinal parasites
anther — in a flower, the part of a stamen which produces pollen, usually divided into lobes by a band of tissue [the connective]
anticholinergic — a substance which blocks or reverses the activity of ***acetylcholine***; in the CNS this may result in delirium and hallucinations, amongst other effects [eg. see **Datura**]
antidiarrhoeic — acts against diarrhoea
antidipsogen — antagonises craving for alcohol
antifilarial — substance which kills filaria [parasitic nematode worms]
antinociceptive — antagonises nerve pathways involved in pain perception
antioxidant — neutralises damaging oxygen free-radicals
antiphlogistic — relieves inflammation or fever
antipyretic — reduces fever by lowering body temperature
antiseptic — destroys or inhibits growth of pathogenic bacteria
antispasmodic — reduces spasmodic activity in smooth muscle; often entails a nervine and general muscle-relaxant action
antitussive — suppresses coughing
anxiolytic — relieves anxiety and nervous tension
aphasia — also called dysphasia; a disease of the dominant hemisphere of the brain [eg. the left hemisphere for a right-handed person], affecting generation, content and understanding of language
aphrodisiac — incites sexual desire, or enhances sexual experience and/or ability
apiculate — terminating abruptly to a small point
arrhythmia — deviation from normal heart rhythm
arthralgia — joint pain without swelling or other arthritic symptoms
ascetic — person practising self-imposed hardship and denial of comforts, often including self-imposed physical and mental ordeals, usually in the pursuit of spiritual illumination
astringent — causes contraction of cells; observe the 'puckering' effect of black tea [see **Camellia**] in the mouth
ataxia — a state in which shaky and unsteady movement is observed
ayahuasca analogue — a combination of two or more plants or chemical substances, at least one containing an MAOI and the other/s containing ***DMT*** [or sometimes ***5-methoxy-DMT***], used to produce an effect analogous to that produced by ayahuasca containing **Banisteriopsis** and **Psychotria** or **Diplopterys**
ayahuasquero — shaman proficient in the use of ayahuasca [see **Banisteriopsis**]
ayurvedic medicine — therapeutic system based on ayurveda, 'the science of life', originating from India
bioassay — to determine the activity of a substance by ingestion, preferably self-ingestion — often referred to as the 'Heffter technique', after Arthur Heffter, who was the first person to bioassay a pure psychedelic compound on himself [***mescaline***, in 1897]
brachycardia — shortening of heart beat
bradycardia — slowed heart-rate to less than 50bpm
cannabinoid — any of a group of chemical substances structurally related to ***THC*** [including a tricyclic structure]; or, a substance which binds to cannabinoid receptors [such as ***anandamide***]
cardiotonic — tones and regulates heart activity
carminative — reduces intestinal gas
catalepsy — a symptom of catatonia involving abnormal maintenance of physical postures
catarrh — excess secretion of thick phlegm or mucus
catatonia — abnormal state of mute stupor, in which limbs can be moved by another person without resistance and will remain in the position they are left in for some time [see catalepsy]
catecholamine — chemical substance with two adjacent hydroxy groups on a benzene ring — eg. ***dopamine***
cathartic — laxative
caudate — excessively acuminate
cephalic — of or relating to the head
ch'i — also spelled 'qi' or 'ki'; Chinese word for vital energy of the universe or life force, paralleled by the Sanskrit 'prana'
cholinergic — of or relating to nerves which transmit and/or receive ***acetylcholine***; or a substance which mimics the actions of ***acetylcholine***, or stimulates its production and/or synaptic release
CNS — central nervous system
convolute — with one part wholly wrapped up in another
coriaceous — leathery
covalent linkage — a bond formed by sharing pairs of electrons between atoms
curandera — a female shamanic or medicinal healer
curandero — a male shamanic or medicinal healer
cyanogenic/cyanogenetic — of a plant or chemical compound which may generate cyanide or hydrocyanic acid [HCN] under certain conditions [see *Categories of Psychoactive Chemical Compounds*]
cytostatic — suppresses growth and multiplication of cells
cytotoxic — toxic to cells; sometimes this can be useful in treating cancer, if the cytotoxic activity is selective to tumorous growth
dehiscent — usually of a mature plant reproductive organ, referring to an ability to rupture or split to release seed or pollen
delirium — mental state characterised by disorientation, 'true' hallucinations, and sometimes excitation and delusional behaviour
demulcent — protects mucous membranes, keeping them moist and soothing irritation
diaphoretic — promotes sweating
dioecious — of plants which bear male and female flowers on separate plants
disinfectant — destroys or removes bacteria
dissociation — a state where thoughts and ideas seem to function separately, or removed from, consciousness or 'reality'
diuretic — promotes urine flow
drug — any substance which pharmacologically affects a living organism
d/w — dry weight
dysmenorrhoea — painful menstruation
dysphoria — opposite of euphoria
dyspnoea — difficult or laboured breathing
ecstasy — from the Greek 'ekstasis', roughly meaning 'flight of the soul from the body'; most people associate the word with less extreme sensations of rapture. Today it is commonly synonymous with 3,4-methylenedioxy-*methamphetamine* [MDMA] and its miscellaneous street substitutes or adulterants
emetic — causes vomiting
emmenagogue — promotes menstruation
emollient — soothes and softens skin tissue
empathogen — something which brings about a feeling of empathy with objects, places or other people
endogenous — from within the body
entheobotany — the study of entheogenic plants
entheogen — a substance which 'generates the god within'; sometimes interpreted as 'awakening the god within'. Originally proposed as a replacement term for ***psychedelic***. It is currently little-used; many people dislike the theological connotations of the word, which also is more descriptive of certain contexts of use and of a possible subjective effect out of many, rather than of a reliably replicable pharmacologic effect
enzyme — a complex protein which catalyses specific chemical reactions on the substrates with which it binds temporarily

ethnobotany — the study of the use of plants by humans
eupeptic — something which aids or maintains normal digestion
euphoria — 'bearing well'; generally associated with feelings of bliss, joy and good cheer in varying degrees
exogenous — from outside of, or alien to, the body; originating externally
expectorant — loosens phlegm or sputum, aiding in its removal
expert — a type of imaginary being invented by humans
febrifuge — reduces or prevents fever
filiform — slender and thread-like
fumigant — something smouldered or burned to treat a person or place with fumes or smoke, usually in a purifying context [spiritually or medicinally therapeutic]
galactagogue — promotes milk flow
GC — gas chromatography
glabrous — smooth
glaucous — covered with a fine waxy bloom
glucoside — a glycoside, in which the sugar constituent is glucose
glycoside — chemical compound derived from amino acids and containing one or more sugar moeities
habituation — psychological dependence on something that is used or done regularly
haemolytic — destroys red blood cells
haemoptysis — coughing up blood
haemostatic — prevents haemorrhage or bleeding
hakim — Muslim physician, judge or other authority
hallucination — a perception of any of the senses which can not be observed by others, and is thus deemed not to exist, or to be a delusion; in the case of psychoactive drugs, a hallucination is defined by the perceiver not recognising that the perception is a result of the effects of the drug and believe it to be physically real
hallucinogen — technically, a substance which causes hallucinations; often mis-applied to many psychedelic or visionary substances which do not usually cause 'true' hallucinations in most cases
hardhead — colloquial term referring to someone who is more resistant than most others to the effects of some psychoactive substances; such people are usually affected normally or even more strongly by at least some psychotropes
harv. — harvested
herb — botanically, a small tender plant; otherwise, any plant or plant part with medicinal or culinary virtues
HPLC — high performance liquid chromatography
hyperalgesia — increased perception of pain
hyperpnoea — increased rate of breathing, related and proportional to increased metabolism due to exertion
hypertension — high blood pressure
hypnagogic — of mental imagery experienced while going to sleep
hypnotic — a substance that causes sleep by depressing CNS function; I prefer to use the term to describe substances that induce a hypnotic state in the sense of trance, or detached but focused thought, which does not actually lead to sleep, unlike a narcotic or soporific, except in high doses
hypotension — low blood pressure
hypoxaemia — state of reduced oxygen content in arterial blood
icaro — magical chant or melody used by Amazonian shamans in healing or divinatory sessions; icaros are usually learned whilst under the influence of a psychotropic substance [such as ayahuasca], and different icaros have different effects, from calling on the healing power of a plant, to calling particular spirits, to simply calming a distressed patient
imbricate — overlapping at the margins in a parallel fashion
indigenous — originally native to a particular area
inebriation — an intoxication involving 'extravagant exhilaration' or ecstasy [see above]; often used to refer to alcohol intoxication
inflorescence — structure of flowering plants which bears the flower or flowers [the reproductive organs]
intoxication — referring to a state involving symptoms of 'toxicity' from ingestion of a drug; a very broad term which may refer to anything from nausea and vomiting, to varying states of desirable or undesirable inebriation, or psychotropic effect
in vitro — outside of a living organism [ie. in a test tube]
in vivo — inside of a living organism
involute — with edges inrolled spirally
ischaemia — insufficient blood flow resulting from blockage or constriction of blood vessels leading to a part of the body
lamina — blade of a leaf
ligand — in neurochemistry, something which has an affinity for a particular receptor type
lipid — fatty compound [including fats, steroids] that is soluble in organic solvents, but not in water
LSD — d-lysergic acid diethylamide or LSD-25 [also known as 'acid'], a synthetic psychedelic drug derived from ergot alkaloids [see **Claviceps**]
lyophilise — to dry by freezing in a high vacuum
macerate — process of soaking, usually to soften or break up tissues
MAOI — monoamine-oxidase inhibitor
medicine wo/man — a person proficient in healing, usually with herbs; not the same as a shaman, who has a broader function, though the two often overlap in practice
miotic — constricts the pupil of the eye
moeity — a chemical structure part of, or attached to, another; eg. ***tryptamine*** with an N-methyl moeity is also known as ***N-methyltryptamine***
MS — mass spectrometry
mucronate — abruptly terminating in a short, hard point
mutagenic — promotes cell mutation
mydriasis — dilation of the pupils
myosis — constriction of the pupils [also spelled miosis]
narcotic — a substance which diminishes consciousness and relieves pain; widely misapplied to all illegal drugs
nervine — has a tonic action on nerves
neuraesthenia — syndrome involving headache, dizziness, fatigue, irritability, anxiety and intolerance of noise
neuralgia — sharp burning or stabbing localised nerve pain
neuroleptic — antipsychotic, generally acting as a sedative tranquilliser
neurotoxic — harmful to nerve cells; many neurotoxins cause damage by causing excessive depolarisation or excitation of neurons
neurotrophic — relating to growth and nutrition of neural tissues
neurotropic — growing towards, or having an affinity for, neural tissues
nöotropic — a substance which enhances cognition, yet usually producing no marked psychotropic activity at normal doses; collectively, such substances are often called 'smart drugs'
nystagmus — rapid and involuntary eye movement
oedema — also known as dropsy; swelling of body tissues from excessive accumulation of fluids
oneirogen — stimulates dreaming, enriches dream content
ophthalmic — related to the eyes
ordeal poison — a toxic substance administered in some indigenous cultures [particularly in parts of central Africa] to determine guilt or innocence in important matters. Usually innocence is shown if the person under trial vomits up the substance [in the case of oral ordeal poisons]; otherwise, death may result, or at least violent gastric pain, signifying guilt
oxytocic — stimulates uterine contractions
paraesthesia — spontaneous tingling sensations, sometimes referred to as 'pins and needles'
paralytic — relating to paralysis; or, a substance which causes paralysis
PEA — phenethylamine, β-phenethylamine
pediculicide — a substance which kills lice
pers. comm. — personal communication [from another person], anonymous unless a name is given
pers. obs. — personal observation, whether it be a hypothesis, deduction, or derived from personal experience. This book is full of personal observations from the author, but the term is only used as a reference where necessary to avoid confusion with other referenced comments listed in close proximity
phenylpropane — chemical substance with a three-carbon side chain attached to a benzene ring
phenylpropanoid — chemical substance similar to, or synonymous with, phenylpropanes
phenylpropene — a kind of phenylpropanoid found in essential oils, which is lipid-soluble and aromatic
pheromone — a chemical which serves to signal messages between members of the same species, or sometimes between different species; pheromones are most famous for those which signal sexual interest or receptiveness, or which attract members of the opposite sex so that mating may occur
phytochemical — a chemical produced by a plant through natural processes; it is questionable whether this term can be applied to chemicals produced by plants purposely fed synthetic or exogenous precursors, which would otherwise not be found in the plant
precursor — in chemical terms, a chemical which is used to produce another chemical — eg. ***tryptophan*** is a precursor to ***tryptamine***
pruritis — itching
psychedelic — roughly meaning 'mind-manifesting', this word [coined as an alternative to the (usually) inaccurate term 'hallucinogen'] should correctly be spelled 'psychodelic' though this never caught on due to negative connotations of the prefix 'psycho'; generally referring to substances which elicit elaborate alterations in visual and thought processes, especially LSD, ***DMT***, ***psilocin*** and ***mescaline***; also used to refer to art or music evocative of a psychedelic state; currently disliked by some due to its mainstream association with 'hippies' and late 1960's 'psychedelic culture'
psychoactive — of something which alters consciousness or state of mind

psychonaut — a person who embarks on explorative journeys through the mind, through the use of psychoactive drugs, or by other effective means
psychoptic — a substance that has visionary properties; suggested by some as an alternative to 'psychedelic' and 'entheogen'
psychotrope — a substance that has psychotropic properties
psychotropic — a catchier way of saying psychoactive
purgative — a less embarrassing way of saying laxative
reality — many people devote their entire lives trying to figure out what it is, so I won't make any futile attempts to define such a bag of mystery and intrigue. Generally stated to be 'that which is real' [by consensus], but as reality seems to differ for everyone this is not a very acceptable definition
religion — secularised and dogmatised spirituality, its adherents often [but not always] lacking in true spiritual depth and understanding
revolute — with edges inrolled spirally, on the underside
rhizome — more or less horizontal creeping root, usually branching and sending up new growth away from the main plant
rubefacient — something which warms the skin and causes reddening
sacrament — a substance consumed, or act performed, ritually for the purpose of communion with god/s or 'higher realms'
saddhu — Hindu wandering 'saint' or spiritual seeker, generally a life occupation; many saddhus are also ascetics
sage — person renowned for being profoundly wise; also referring to **Salvia** spp. and some **Artemisia** spp.
schizophrenia — blanket term used to describe a variety of similar mental disorders, characterised by 'delusions', tenuous contact with consensus reality, and difficulty in functioning socially; sometimes hallucinations are present; is not the same as 'multiple-personality disorder' [a.k.a. 'split personalities']
serotonergic — of or pertaining to neurons associated with *serotonin*; or substances which mimic its effects
shaman — from the Siberian Tungusian word 'saman', referring to the 'medicine-men' or so-called 'witch-doctors' of the area, though now generally used to refer to similar practitioners worldwide; shamans use psychoactive plants and/or other methods to reach trance-like states or contact spirit realms for divination and healing
softhead — a person who is more easily affected by certain psychoactive substances, often with some exceptions [eg. a person may be a 'softhead' for **Cannabis** but not for alcohol, and vice versa]
somatic — relating to the body
soporific — produces sleep
sorcerer — practitioner of magic, usually used to harm or influence others, or for selfish means
spasmolytic — something which relieves spasms of smooth muscle
spirit — 'an ineffable vital quality that provides the link between the mundane and the divine' could be one way of attempting to capture it in words
spirituality — personal experience of the divine translated into one's daily life; non-secular, personalised religion
SSRI — selective *serotonin* re-uptake inhibitor
SRI — *serotonin* re-uptake inhibitor
stamen — of the male part of a flower consisting of a filament supporting an anther
stomachic — improves digestion and soothes stomach aches
stupefacient — a substance which causes one to become stupefied
sudorific — same as diaphoretic [see above]
sympatholytic — something which antagonises sympathetic nervous system activity
sympathomimetic — referring to symptoms of sympathetic nervous system stimulation, or something that causes them
synaesthesia — a merging of sensory perceptions, eg. seeing sound, tasting colour etc.
synergy — an action between two or more substances or things, which has an effect greater than the sum of the individual parts
tab. — tablespoon
tachycardia — increase of heart rate above the normal
TCM — Traditional Chinese Medicine
teratogen — causes birth defects
terete — not angular
THβC — 1,2,3,4-tetrahydro-β-carboline, also occasionally known as tryptoline
THIQ — 1,2,3,4-tetrahydroisoquinoline
TLC — thin-layer chromatography
tonic — a substance which improves and regulates the function of specific organs, or the body as a whole
topical — of something applied externally to the skin, usually to a specific area where an afflicition is located
torpor — state of sluggishness, decreased responsiveness
trachoma — an eye disorder which is a severe and contagious form of conjunctivitis
tranquilliser — [U.S. spelling - tranquilizer] a substance which produces calming effects
tremorgen — a substance which promotes fine-tremors
tripping — experiencing the effects of a psychedelic drug, whether one has been consumed or not
tsp. — teaspoon
urtication — burning or itching sensation, usually on the skin; can be due to hives or nettle sting [see **Urtica**]
vasoconstrictor — causes constriction of blood vessels
vasodilator — causes dilation of blood vessels
vasopressor — something which stimulates contraction of blood vessels, resulting in increased blood pressure
vegetalista — Amazonian shaman or curandero/curandera who utilises plants
vermifuge — something used to expel intestinal worms
visionary — a substance which can induce visions; also used to describe art or people that communicate visionary states or 'out-there' concepts
vulnerary — wound-healing
War on Drugs — a misguided exercise in futility, which serves only to alienate, incarcerate, and otherwise destroy the lives of large sections of the community, without decreasing the prevalence of drug use, as well as increasing the risks of non-prescribed drug use and producing flow-on social problems which would otherwise be trivial or non-existent
w/w — wet weight, fresh weight

Brush, D.E. et al. 2004. "Monoamine oxidase inhibitor poisoning resulting from internet misinformation on illicit substances." J. Toxicol. Clin. Toxicol. 42(2):191-195. [Note: this article is rather hysterically anti-drug, and seems to consider all "partisan" [as opposed to anti-drug] drug-related websites as sources of "internet misinformation", and all 'underground' scientists such as Jonathan Ott as suspect sources of information - where often the real problem is of young psychonauts failing to do their research properly and experiment with caution. The supposed peer-rated drug-knowledge credentials of emergency-room admittees are used to further encourage a fear of all psychedelic substances (implying that there is no safe self-experimentation), ignoring the fact that a lot of young psychonauts (and some older ones) are simply far less knowledgeable of the subject than they or their friends think they are, and hence tend to take stupid risks more frequently. In my opinion this just strengthens the need for books like this one you are now reading!]

ILLUSTRATION CREDITS

All illustrations have been executed by the author. Many are closely based on original artworks or photographs by others, as listed below. The prime criterion for including illustrations was accurate detailing to aid identification [along with the written descriptions]. Use of creative license by an illustrator can distort the accurate representation of a biological entity. Many of the species illustrated within were not available in a living state for first-hand study by the author [not including those investigated in a dry state], lacking the time and funding required for the extensive travelling such an undertaking would involve. Use of high definition colour photographs taken by the author and donated by others would of course have been preferable, but such an option was not available within the cost restrictions involved in producing this self-funded work. Black and white photographs often do not reproduce clearly enough to be useful for any but a cursory impression. A planned future revised edition of this work is hoped to include a large array of original colour photographs.

It is for these reasons the author reluctantly decided that attempting re-worked versions of the art of others was the best viable option for this current edition. I did not wish to directly reprint them, lacking the time and resources to secure copyright permission from all relevant sources, and also recognising that some of the original artworks could do with some improvement. Previously published originals were enlarged, traced for the general outlines, then painstakingly hand-detailed taking care to give the illustration dimension and to attempt to correct artistic embellishments, errors or unclear areas of the originals, based on comparison with botanical or zoological descriptions, as well as other illustrations or photographs when available. Some of these originals were so good they could not really be improved upon, though the reproductions of these are still different from the originals. Original artists are listed below, where their names could be located, followed by reference to the publication in which original artworks were printed. Some publications failed to specify the artists responsible for particular artworks, or failed to name any of the artists used; in such cases, only the publication in which the illustration appeared has been given as a reference.

List of Illustrations

cover illustration	original by the author.
simplified human brain cross-section	adapted from originals by C. Vadala, in Diamond et al. 1985, and M.M. Phelps & J.M. Roerig in McMurtrie & Rikel 1991.
chakras and nadis	original by the author.
chillum in hand	from photo in French 1976.
assorted pipes	originals by the author.
Acacia obtusifolia	after K. Thiele, in Butcher et al. 2001.
Acorus calamus	in Kirtikar & Basu 1980.
Amaranthus spinosus	after F. Owner, in Womersley ed. 1978.
Amsonia tabernaemontana	in Gleason 1952.
Anadenanthera peregrina	after I. Brady, in Furst 1976.
Ariocarpus fissuratus	after L.B. Hamilton, in Benson 1982.
Artemisia absinthium	in Gleason 1952.
Banisteriopsis caapi	after E.W. Smith, in Furst 1976.
Boophane disticha	after E.M. Tweedie, in Agnew 1974.
Brugmansia x candida 'Buyés'	after S. Amii, in Bristol 1969.
Bufo alvarius	from photo by A. Norman, in Staniszewski 1995.
Calea zacatechichi	after I. Brady, in Schultes & Hofmann 1980.
Calliandra anomala	after F.E. Runyan, in Emboden 1979a.
Calonyction muricatum	in Chopra et al. 1965.
Camellia sinensis	after B.E. Nicholson, in Harrison et al. 1985.
Canavalia maritima	after L. Elkan et al., in Harden ed. 1990-1993.
Canella winterana	after originals in Bailey & Bailey 1976, and Fawcett & Rendle 1926.
Catha edulis	after 'J.C.W.', in Exell et al. ed. 1960-1993.
Clerodendrum floribundum	after M. Andrews, in Aboriginal Communities 1988.
Coryphantha macromeris	after L.B. Hamilton, in Benson 1982.
Crenidium spinescens	after R. Roden, in D'Arcy ed. 1986.
Crocus sativus	after Faguet, in Pammel 1911.
Crowea saligna	after L. Elkan et al., in Harden ed. 1990-1993.
Cypripedium calceolus	in Gleason 1952.
Desmodium gangeticum	after C.C. Huo, in Chang et al. ed. 1977.
Dictyoloma incanescens	in Engler et al. 1897.
Dictyonema sp. 'nenendape'	from photo, in Davis & Yost 1983.
Duboisia hopwoodii	from photo by M. Letnic, in Letnic 2000.
Echinocereus triglochidiatus var. melanacanthus	after L.B. Hamilton, in Benson 1982.
Ecklonia maxima	after R.H. Simons, in Lüning 1990.
Erythroxylum coca var. ipadu	after 'E.W.S.', in Schultes & Raffauf 1990.
Ferraria glutinosa	after J.C. Manning, in Exell et al. ed. 1960-1993.
Grewia villosa	after 'W.E.T.', in Hutchinson & Dalziel 1954-1972.
Ilex paraguariensis	in Fridericus & De Martius ed. 1965-1975.
Isotoma petraea	after N. Oram, in Harden ed. 1990-1993.
Justicia pectoralis var. stenophylla	after E.W. Smith, in Schultes & Hofmann 1980.
Kaempferia galanga	after I. Brady, in Schultes & Hofmann 1980.
Laburnum anagyroides	after T.J. Cobbe, in Blackwell 1990.
Lancea tibetica	after W. Fitch, in Hooker 1857.
Leonurus sibiricus	in Steward 1958 and Wagner et al. 1990.
Macropiper excelsum	after N. Adams, in Poole & Adams 1990.
Magnolia virginiana	in Gleason 1952.
Mammillaria craigii	from photo by M.S. Smith, courtesy of M.S. Smith.
Mascagnia psilophylla	in Engler & Niedenzu 1928.
Methysticodendron amesianum	after E.W. Smith, in Schultes 1955b.
Monadenium lugardae	from photo by the author.
Monotropa uniflora	after W.B. Zomlefer, in Zomlefer 1994.
Mucuna pruriens	in Kirtikar & Basu 1980; seed from specimen in author's possession.
Nananthus albinotus	after B.O. Carter, in Jacobsen 1960.
Nicotiana tabacum	in Gleason 1952.
Nymphaea ampla	after F.E. Runyan, in Emboden 1979a.
Oncidium cebolleta	after 'G.C.K.D.', in Dunsterville & Garay 1979.
Opuntia acanthocarpa var. acanthocarpa	after P. Roetter, in Benson 1982.
Pagiantha cerifera	after D. Storez, in Boiteau 1981.

Pancratium trianthum	after E.M. Tweedie, in Agnew 1974.
Passiflora incarnata	after W.B. Zomlefer, in Zomlefer 1994.
Pedicularis canadensis	in Steyermark 1963.
Penicillium aurantio-virens	after R.A. Samson, in Domsch & Gams 1993.
Pereskia grandifolia	after L.B. Hamilton, in Benson 1982.
Peripentadenia mearsii	after L.S. Smith, in Smith 1956.
Petalostylis cassioides	after A. Barley, in Ross 1998.
Petunia violacea	after E.A. Vega, in Burkart 1979.
Phyllomedusa bicolor	from photo by A. Norman, in Staniszewski 1995.
Physochlaina praelta	in Kirtikar & Basu 1980.
Pilocarpus organensis	in Kaastra 1982.
Pithecellobium diversifolium	in Fridericus & De Martius ed. 1965-1975.
Przewalskia tangutica	after J.F. Wang, in D'Arcy ed. 1986.
Psychotria viridis	after I. Brady, in Furst 1976.
Rhizopus sp.	in Gilman 1957.
Salvia divinorum	after I. Brady, in Schultes & Hofmann 1980.
Sceletium tortuosum	from photo by the author.
Sclerotinia megalospora	after Woronin, in Von Tubeuf 1897.
Scopolia carniolicoides	after J.F. Wang, in D'Arcy ed. 1986.
Spiraea caespitosa	after J.R. Janish, in Abrams 1940-1944.
Stenocereus beneckei	from photo in Haustein 1991.
Streptopus amplexifolius	in Gleason 1952.
Symonanthus aromaticus	after R. Roden, in D'Arcy ed. 1986.
Thuja occidentalis	in Gleason 1952.
Tillandsia mooreana	after photo by D. Butcher, at http://www.fcbs.org/pictures.htm
Tribulus terrestris	in Exell et al. ed. 1960-1993; fruit segment partly from dried specimens in author's possession.
Trichocereus peruvianus	from photo by M.S. Smith, courtesy of M.S. Smith.
Turbinicarpus schmiedickianus var. schwarzii	after photo by G. Gröner, in Cullmann et al. 1986.
Utricularia minor	in Gleason 1952.
Voacanga africana	after 'J.W.', in Exell et al. ed. 1960-1993.

INDEX

abalone – 386
Abies – 19, 371
abre-o-sol – 187
absinthe – 57, 92-93, 177, 277
Abudefduf – 71-73
Abuta – 366
Abutilon – 371
Acacia – 19, 48, 56-58, 61, 65-71, 82, 160, 204, 244, 290, 361, 369, 388
Acalypha – 371
Acampe – 344
Acanthomyops – 384
Acanthopanax – 164
Acanthoscurria – 382
Acanthurus – 71-73
Aceras – 358
acetophenone – 341, 390
acetyl-carnitine – 390
acetylcholine – 22-26, 29, 32-33, 60, 80, 89, 131, 137, 169-170, 197, 206, 226, 237, 241, 293, 341, 357, 363, 372-373, 376, 382-383, 390
Achatina – 386
Achillea – 358, 377
achuma – 333-334
achuni-casha – 370
achuni-caspi – 370
achunisanango – 366
Achyranthes – 365, 373
Aconitum – 11, 58, 125, 236, 309, 352, 359
Acorus – 57-58, 73-74, 92, 94, 117, 175, 226, 237, 373, 375
Acraea – 74
Acremonium – 176-177, 217-218, 315-316
Acridocarpus – 363-364
Acris – 387
Acromyrmex – 384
Actaea – 361
ACTH – 25-28, 32-33, 35, 39, 76, 124, 135, 390-391
Actinidia – 30, 75, 377, 384, 390
actinidine – 75, 344, 377, 384-385, 390
Actinopyga – 75
acupressure, acupuncture – 35
Adalia – 384
Adansonia – 381
Adenanthera – 360
Adenia – 74
adenosine – 20, 26, 129, 138, 180, 345-346, 390
adrenochrome – 24, 32, 193, 288, 390
adrenocorticotropin – see ACTH
adrenoglomerulotropin – 24, 155, 348, 391
adrenaline – see epinephrine
adrenolutin – 24, 27, 391
Adriana – 357
Aegiale –385
Aerva – 371-372
Aesculus – 75-76
Aethusa – 396
Aextoxicon – 183

Meconopsis – 373
Medinilla – 191
meditation – 9-10, 18, 22, 34, 36-40, 43, 113, 125, 165, 294
Megalopyge – 385
Megoura – 385
Meixner test – 49
Melaleuca – 376-377
Melanophryniscus – 387
melatonin – 23-24, 26-35, 39, 176, 195, 201, 270, 306, 325, 371, 408
Melicope – 229
melilot – 359
Melilotus – 359
Melissa – 52, 57, 378
mellow yellow – 238
Melocactus – 369
Meloë – 384
Melolobium – 363-364
melon – 29, 58, 234
membrillo – 359
Memnoniella – 382
Menispermum – 373
Mentha – 57, 130, 213, 358, 378
Menyanthes – 377
Mentzelia – 358
5-MeO-DMT – see 5-methoxy-DMT
Mephitis – 366
Meriones – 165
Meripilus – 381
Merostachys – 385
Merremia – 89-90
mescal – 219, 331, 385
mescal bean – 311
mescaline – 14, 19, 23-24, 27, 34, 39, 44, 67, 70, 74, 91, 98, 122, 141-142, 182, 184-185, 203, 219-220, 227, 240, 251, 268-269, 282, 293, 314-315, 335-336, 339, 358, 362, 367-369, 385, 408
mesembrine – 153, 242, 302-303, 364, 409
Mesembryanthemum – 153, 301-303
Mesobuthus – 383

mesquite – 283
Mestoklema – 301-303
Mesua – 375
methamphetamine – 14, 16, 26, 67, 70, 165, 392, 394, 409
methionine – 22-23, 30-31, 39, 61, 102, 380-381, 409
5-methoxy-DMT – 19, 22-24, 31-33, 37, 39, 43, 45, 49, 60, 67-70, 72, 79-80, 83, 108, 110, 153, 155-156, 158-159, 161-162, 173, 192, 203, 207, 215, 229, 231, 237, 252, 272-274, 276, 333, 348-349, 372, 379-380, 409
6-methoxyharmalan – 24, 39, 348, 410
5-methoxytryptamine – 22-24, 39, 49, 155, 273, 329, 348, 382, 410
methyleugenol – 20, 68, 74, 93-95, 103, 128, 135, 146, 198, 213, 216, 230, 239, 242, 249, 277-279, 301, 312, 345, 351-352, 367, 369-370, 377, 410
methylisoeugenol – 20, 94, 144, 152, 198, 239, 279, 377, 410
N-methyltryptamine – 24, 67-70, 83, 153-154, 158-159, 187, 207, 231, 259, 273-274, 292, 317, 324, 327, 348, 351, 369, 386, 410
methysticin – 20, 279-280, 410
Methysticodendron – 229
Metteniusa – 369
metzollin – 226, 368
Mexican tarragon – 324
mezcal – 57, 150, 311, 338, 383, 385
mezcal worms – 385
Michelia – 230
Miconia – 116, 369
Microporellus – 180
Microstylis – 360
Mildbraedia – 362
milkbush – 248
milk thistle – 62, 389
milkweed – 282
milkwort – 282
millet – 56-57, 95, 130-131, 361, 379
Millettia – 364
millipedes – 383
Mimosa – 57, 230-232, 281
Mimusops – 322
mint – 20, 29, 52, 57, 130, 208, 211, 213, 358, 377
Mirabilis – 232
misha – 105, 203, 223, 334-335, 362
mistletoe – 11, 66, 139, 161, 223, 236, 283, 363
Mitchella – 191, 232
mitra – 367
Mitragyna – 11, 232-234, 346
mitragynine – 19, 233, 340, 410
mitraphylline – 68, 233, 340, 346, 410
miya – 59, 363
MMDA [3-methoxy-4,5-methylenedioxy-amphetamine] – 20, 411
MMDA-2 [2-methoxy-4,5-methylenedioxy-amphetamine] – 20, 393, 395
MMDA-3a [2-methoxy-3,4-methylenedioxy-amphetamine] – 20, 397
mohodu-wa-pela – 364
Mojave desert rue – 328
mokei – 366
mokgopha – 365
Molinea – 131
molluscs – 244, 385-386
moly – 361
Momordica – 234
Monadenium – 235
monarch butterfly – 385
Monema – 385
mongoose plant – 379
monitor lizard – 388
monkey frogs – 275
monkshood – 58, 359
Monodora – 234-235
Monomorium – 384
Monopteryx – 376-377
Monostroma – 399
Monotropa – 235-236
Montrichardia – 59
moonflower – 199
morara o moholo – 61, 364
Morchella – 380
Morinda – 57, 363
Morindae – 375
Moringa – 363
Mormon tea – 165
morning glory – 11, 19, 51, 89, 130, 137, 146, 199-202, 296
morphine – 19, 25-26, 30, 32, 35, 89, 109, 210, 257, 260-261, 304, 350, 366, 373, 384-385, 410-411
Mostuea – 364
motherwort – 214-215
mothokho – 61, 199
mothoto – 61, 146
moths – 138, 150, 171, 385
motsitla – 61
mould – 30, 49, 57, 95-96, 119, 121, 153, 176, 180, 195-196, 245-246, 268, 295, 307, 329, 341, 343, 382, 395
mountain laurel – 311, 358
mountain tobacco – 167, 244, 358
morel – 380
Morelia – 180
Morus – 236, 385
Moschus – 366
motelo huasca – 58
Mucor – 57, 153, 176
Mucuna – 60, 200, 236-237, 333
mucura – 370
Mugil – 71-73
mugwort – 92-93, 223, 359
muira puama – 61, 293
mukhuisa – 365
muk muk – 366
mukuyasku – 59
mulberry – 227, 236
mullein – 358
Mulloidichthys – 71-73
mulungú – 168-169, 296
mummies – 11, 127, 165, 205, 247, 381
murcohuasca, murcuhuasca – 369
murere, mureru – 59
Murex – 386
Murraya – 377
murucuja – 262-263
Musa – 54, 61, 123, 170, 191, 237-238, 245, 294, 357
Musanga – 322, 363
Musca – 385
muscimol – 19, 79-80, 387, 361, 411
mushroom, edible – 30, 79, 254
music – 18, 34-36, 43-45, 382
musk – 67, 117, 366
musk seed – 361
mustard – 29, 88, 104, 227, 353, 374
Mycena – 238-239, 382

scopolamine – see hyoscine
scopoletin – 20, 76, 84-85, 90, 93, 97, 106-107, 121, 123, 137, 151-152, 188, 190, 197, 201, 207, 213, 246, 264, 272, 276, 304-305, 309, 311, 332, 341, 350, 361, 364, 368, 372, 378, 416
Scopolia – 58, 305
scorpions – 58, 303
Scotch lovage – 376
screw pines – 258-259
Scurrula – 236
Scutellaria – 11, 135, 148, 283, 305-306, 377
scute turtle – 388
Scyphophorus – 385
Scytonema – 157
sea bream – 72
sea buckthorn – 379
sea cucumber – 75
sea daffodil – 258
sea dragon – 386
sea ear – 386
sea fan – 386
sea holly – 359
sea horse – 386
sea snails – 385-386
sea sponges – 309-310, 386
sea squirt – 386
sea toad – 60
sea turtle, green – 388
sea urchin – 386
seaweed – 163, 370
sea worms – 386
Sebastiana – 370-371
Secale – 131-132
secretary bird – 61
Securidaca – 66, 278, 306-307, 359, 364
Securiflustra – 386
Securinega – 376
securinine – 307, 376, 362, 416
sedge grass – 122, 146, 304
Sedum – 412
seharane – 179, 364
sehoere – 61, 146, 200, 274

Selaginella – 223
Selago – 223
Selenicereus – 166, 371
semen of the sun – 347
Sempervivum – 412
Senecio – 48, 170, 307-308
senega – 282
Senegalia – 371
Senegal-root tree – 306
senna – 109-110, 209
sensitive plant – 230
sensory deprivation – 33
Sepia – 386
Serenoa – 359
serotonin – 19, 22-28, 30-31, 33-34, 38-40, 49, 55, 60, 79-80, 83, 89, 108-109, 114, 131, 153, 163, 181, 183-184, 186, 195, 206, 231, 237-239, 255-257, 264, 273, 282-284, 288-289, 294, 302, 308, 311, 329, 340-341, 357, 361-362, 369-370, 372-377, 382-383, 385-388, 416
serotonin syndrome – 31, 184, 195, 273, 302, 394
serpent wood – 294
Serrasalmus – 43
Seseli – 309
Setaria – 131, 147
sete mbwunde – 364
sethuthu – 179, 364
setima mollo – 61
seven-banded turtle – 388
sex – 9-10, 15, 21, 23-28, 38, 43
shabu – 394

zorillo – 370
Zornia – 353
Zygaena – 385
Zygocactus – 166
Zygophyllum – 353

SEARCH FOR ULTIMATE TRUTH

many things in one
the way things are
the way things seem to be, and the way things could be
the inexplicable beauty of the evening sun
and the cool luminescence of its sister the moon
the balance of everything
the knowing that every action affects all others
the infinite connection of all parts
each part bearing the signature of the whole
the many faces of every fraction
the delightful order in the divine chaos
as above so below
the acceptance of every occurrence
as part of the game
as another valuable lesson
the knowing of your respective place in the greater whole
and further, of your equality with everything
of returning to the whole
and seeing it was there all along
not separate
not lost in time
bringing knowledge of the untapped strength inherent in all
to affect their destinies, and in course,
the destiny of all
not to overcome or destroy out of hatred
but rather to transform, share
and strengthen all with the virtues
of quiet wisdom, resilience, acceptance and kindness,
the wonders of joy and laughter
admiration for the unsurpassed brilliance
of creation in all its glory and diversity,
knowing of the presence and overlapping proximity
of dimensions and realities
other than the 'regular'
whatever that is
to recall that all
is of one and the same
a single organism beyond ordinary comprehension
constructed of mystery
made cohesive by an elusive truth
divided by confusion and fear
a true paradox
the simplicity and complexity of it all -
the futility of searching for a single phrase
to sum up or define 'the meaning' -
it's right in front of your eyes
reality is yours to explore, shape and create
why, why not?
